So this gunner preferred to seek the seclusion of his stable before the guns began to shoot; he was encouraged to be gun-shy, and to despise any sort of artillery that could not go at a gallop behind horses. His favourite arm was this *corps d'élite*, the plaything of the I.R.C. (Idle Rich Class), very expensive to maintain in peace, and of little proved utility in war commensurate with the cost.

But motor artillery has come to stay as the real artillery, unless "bilked" by the old school. This was the sort required in the war, and in peace it is not eating its head off, like horses in a stable, and is never tired on the march. De Wet was run to earth very soon by a squadron of motor-cars never giving his horses any rest: what our old cavalry tactics never could effect.

The civilian has grasped the paramount importance in modern warfare of heavy long-range artillery; and he must be careful that the lesson has not been lost on the regular gunner, or allow him to return to his ancient, worn-out traditions. Such long-range fire was declared officially of no military value, until our poor fellows came under the accurate fire of the long-range German howitzer, with no protection from our own side.

German science could always astonish our sleepy regular gunner, in providing a gun that could bombard Paris, and London too, when it could be brought up as near as Calais. How much longer would the war have lasted then? although the fire was declared of no military importance by those who did not suffer under it.

This advanced German artillery science, as well as of the chemical and aeronautical science, was the outcome and product of the Military Technical Academy in Berlin, a magnificent institution such as our Ministers thought England was too poor to afford. Sixty officers were under instruction there in a three years' course more thorough than exacted to-day for honours in the university. No wonder our feeble amateur military science went down before such superior training.

I was once privileged to visit the Berlin Academy, under the guidance of Prof. Cranz, and to inspect the instruction in all branches—ballistics, aeronautics, and electricity. There, for one thing, I remember seeing the electrical class occupied in making the antennæ of wireless telegraphy. This was ten years ago, when aeronautical science and flight were derided by our War Office authority, and opposed on the score of economy. We shall not feel safe in England until we set up a rival institution, but it must be as far apart as possible from the Woolwich tradition. South Kensington would be an ideal site, say in the building of the old School of Mines and Naval Architecture and alongside the Imperial College of Science, as the Berlin Academy is a neighbour of the Charlottenburg Technical High School, with the same

advantage of the free use of laboratories and special professorial lectures. Our artillery will then be able to throw off the badge of second class and claim to take the rank of first class again.

A cadet military college can only carry on the initial stage of the education of the artillery officer, and for that it is better for him not to be isolated too early from the other military branches. Many a scheme for the amalgamation of the military colleges will be found pigeon-holed in the War Office, awaiting the pressure required to be exerted on the opportunist. The artillery could then make its selection from the whole list of Army candidates, and with proper prestige secure the pick of the bunch. It would not then have to submit, as at present, to put up with the leavings of the Royal Engineers, and to be branded as second class.

The pick of the officers, after some military service, would be selected for a further course at our equivalent of the Berlin Military Technical Academy, where neither indolence nor apathy was tolerated, but stigmatised as bad form, so I was informed. Here they would find a standard of university rank, in a centre of keen intellectual activity.

But the atmosphere of all Woolwich is close and ill-ventilated. Throw open the window, and let in air and light! The Royal Military Academy there is unhealthy, physically as well as mentally, seated on the safety-valve of the main drainage of all South London. The buildings are antiquated and worn-out, fit only to be mined and blown up at the moon, and then a more healthy atmosphere, physical and intellectual, might be formed. With the solidarity of any other trade union, Woolwich strongly opposed dilution. But Dilution proved the best material, and carried the war to a successful conclusion, and so the insidious efforts at his elimination in peace must be watched carefully, and countered by a plentiful entry of university candidates from the outside.

The country will never cease to shiver at the recollection of our narrow escape from defeat and utter ruin, and will listen to no specious political views of opportunist economy likely to place us again in a state of military inferiority.

Obituary.

DR. RUDOLPH MESSEL, F.R.S.

DR. R. MESSEL died on Sunday, April 18, in his seventy-third year. Death came to him as a happy release but to a large circle of friends familiar with his social qualities and many acts of unostentatious generosity the loss is severe and will be deeply mourned. He had long been one of the most notable of our chemical manufacturers as pioneer founder of a most important industry, for he was the first to produce sulphuric anhydride from its elements on a large scale.

Messel was born in Darmstadt and came to this country, at the conclusion of his university career, shortly before the Franco-Prussian War; when this broke out he returned to Germany and volunteered for service but owing to a physical disability, I believe, he was drafted into the Army Service Corps and was wounded while on ambulance duty. He lost no time in returning to England and became assistant to the late Dr. Squire, a man of considerable ability and originality. Messel had qualified at Tübingen as a chemist under Strecker, who naturally took an interest in the then infant alizarin industry, as he had worked with alizarin. Strecker foresaw the important part that fuming sulphuric acid was to play in the industry and directed Messel's attention to the fact, suggesting that he might well seek to supply the want. Messel, therefore, was fully conversant with what had been done and when Squire, possessed of the same idea as Strecker, suggested to his assistant that he should set to work on the subject, he was soon ready with a process, having at once resorted to the use of platinum as a catalyst in order to bring about the interaction of sulphur dioxide with atmospheric oxygen.

A patent was taken out by Squire in 1875 and he and Messel described their process in a paper read to the Chemical Society early in 1876; but this was not published. Their works were erected at Silvertown, on the Thames; the manufacturing process was rapidly developed through Messel's skill and intense devotion to his task. Not alone were English wants soon met but a considerable quantity of the acid was supplied to the German colour-makers. The Badische Anilin- & Soda-Fabrik was led largely to develop the manufacture of the acid in connection with the production of synthetic indigotin; but the "splash" this firm made in 1900, when it published the results of its experiments in considerable detail, was unwarranted. Practically everything essential then put forward had long been a matter of everyday practice with Messel. Had not commercial considerations prevailed, he might well have upset the patents; but he was ever a man of peace, as well as a modest man, so he made no attempt to claim the credit that was his due. He acquired the German patents at a peppercorn price but his former countrymen never had the honesty to do him public justice.

The writer was a frequent visitor at Silvertown in early days and was always impressed by the remarkably systematic manner in which the works were operated. Messel was ever on the look-out for improvements and ever ready to make them. His chief trial in later years was the difficulty he experienced in persuading his conservative British

partners to consent to the scrapping of inefficient plant and the substitution of improved appliances. A man of great energy, he was ready at all times to work twenty-five hours a day for several days together. He long lived on the works in the most modest quarters and his all-seeing eyes were everywhere. In Germany the success of the great chemical works has been mainly due to the effective co-operation of a variety of workers, representing the different sides of the business, supported by a small army of highly disciplined, qualified scientific assistants; but Messel did everything himself: his versatility was astounding; he was not only chemist but also engineer, works manager and business man; he had no scientific staff but only an assistant or two.

Though a German but a German fired with Jewish imagination, Messel appreciated and practised English methods. Aided only by the most modest resources, he long held his place successfully against his rivals in Germany. Probably much of his early success was due to his sympathetic attitude towards his workmen, by whom he was generally beloved; but Messel was not only a worker, he also played hard. In great social request, he knew everyone: Gilbert was one of his great friends. Of late years Messel had been one of the most familiar and popular figures at the Savage Club.

Messel's eminent scientific services to industry were recognised in 1912 by his election into the Royal Society. No other compliment could have given him greater satisfaction. Though a manufacturer, he lived for science and in the atmosphere of science and not the least of his merits is the example he has thus set. H. E. A.

Prof. A. K. Huntington.

By the regretted death, on April 17, at sixty-four years of age, of Prof. Alfred Kirby Huntington so shortly after relinquishing the chair of metallurgy at King's College, University of London, which he had occupied since 1879, British technical science loses one of its old guard, and both metallurgy and aviation are the poorer by the loss of an indefatigable worker and an outstanding personality.

Though it be admitted that Prof. Huntington's name is linked with no spectacular discovery, his work, beyond its professional duties, was continuous, scholarly, and of marked originality. In both respects he therefore exercised a determinative moulding influence upon the two generations of men he trained in this rapidly widening field of science. His career, indeed, coincided with what we may justly regard as the Renaissance of non-ferrous metallurgy. For nearly forty years he was invariably abreast, more usually in the forefront, of the many new departures which have marked it. A physicist as well as a chemist, his researches on the micro-structure of metals and on "corrosion" have added essentially to our metallographic knowledge; his paper on "The Concentration of Metalliferous Sulphides by Flotation," read before the Faraday Society in 1905, broke ground which has been gratefully cultivated by others, and provided the starting-point for fresh researches; whilst in the discussion of such diverse technics as those of copper-smelting, cyanidation, nickel metallurgy, etc., many have owed essential enlightenment to his suggestions and criticisms, imparted with a kindly, if somewhat gruff, sententiousness.

Prof. Huntington rendered yeoman service in the earlier development of several of our now important technical associations; thus one recalls his two papers (upon "The Mexican Amalgamation Process" and "The Metallurgy of Nickel and Cobalt") which were read at the first annual meeting of the Society of Chemical Industry in 1882. Later he was actively interested in the formation of the Institution of Mining and Metallurgy, becoming its second president in 1894, and remaining an honoured member of council until his death. The mere enumeration of his contributions to its Transactions occupies a whole page of index. In 1913 he succeeded to the presidential chair of the Institute of Metals, and to that society he gave of his energy and experience with equal freedom. During the war his specialised knowledge of high explosives was placed at the disposal of, and fully utilised by, the Admiralty.

A marked characteristic of Prof. Huntington's metallurgical outlook was its practicality and its constant insistence upon the economic aspect of the problem under consideration. His motto might seem to have been: "First write your equation in economics, and the remaining 20 per cent. of technics will be easily and better supplied thereafter"—though it must be admitted that he could be unsparing if that balance appeared faulty!

Prof. Huntington's intense practical interest in aeronautics, which advancing years were powerless to quench (since, in addition to his exploits in ballooning, he was until quite recently his own pilot and flew his own 'plane), made him famous to a wide circle; but it is to his services to modern metallurgy that special tribute is due.

Dr. A. J. Chalmers.

The death of Dr. A. J. Chalmers in Calcutta on April 5 causes a gap in the ranks of British workers in tropical medicine, and will also be deeply regretted by his many friends in this country, as well as in the various Colonies in which he held important posts. The son of a Wesleyan minister, Dr. Chalmers was born in London in 1870, but began his career at University College, Liverpool, which at that time formed part of Victoria University. His career in the Medical School during his student days was brilliant, and it was soon apparent that he had a bright future before him. He gained the Holt fellowship of his college in 1890 and 1891, and obtained honours on taking his degree as M.D. Soon after

taking his F.R.C.S. (England), he had a great desire to travel, the tropics especially having an attraction for him, and he joined the West African Medical Service in 1897. He served as a medical officer with the Ashanti Field Force in 1900, and was with the British troops that were besieged in Kumasi, who, after some time, gallantly broke through the native hordes and regained the coast. Dr. Chalmers attended to the sick and wounded with great energy and devotion and was mentioned in despatches by the commanding officer, and received the medal with a clasp. In 1901 he accepted a post under the Ceylon Government as registrar of the Ceylon Medical College. Here his capabilities as administrator and organiser were brought into full play. He soon developed this institution into an excellent medical school, the licence of which is now recognised by the General Medical Council.

While in Ceylon Dr. Chalmers first turned his attention to the tropical diseases that came under his notice, and never spared himself in working among the resident Europeans and natives who came to him. Resigning his position in Ceylon in 1902, so that he might devote more time to the study of tropical diseases and parasitology, he returned to England. It was then that he conceived the idea of writing a much-needed manual on tropical medicine; and in collaboration with his colleague, Dr. Castellani, in Ceylon, he began the work which will remain a monument to his memory. The preparation of "The Manual of Tropical Medicine," which has now reached its third edition, cost him a great amount of time and labour. He was an ardent worker in many fields, and carried on research not only in pathology and bacteriology, but also in parasitology, especially in connection with diseases of the tropics. His work on the Mycetoma will always be connected with his name.

From 1912 Dr. Chalmers devoted more than a year to the study of the cause of pellagra, and in company with Dr. Sambon visited Italy and Rumania. On his return he carried on researches in this country, with the result that cases of pellagra, a disease unknown to be endemic in Great Britain, were found in Hertfordshire and Scotland. Later he visited Egypt and travelled up the Nile with the same object, and accumulated much valuable data in connection with the study of pellagra and other diseases such as endemic hæmaturia.

On his return to England Dr. Chalmers gave some time to the study of the history of medicine, and became an enthusiastic lover of ancient literature—especially that dealing with the medical art. After some time he felt again the call of the East, and often expressed a wish to return there. In 1913 he accepted a post as director of the Wellcome Research Laboratories at Khartum, which he filled with conspicuous success. He became a member of the Central Sanitary Board, and also of the Sleeping Sickness Commission of the Sudan. Dr. Chalmers continued there until a short time ago, when he left the Sudan, accompanied by his wife, with the object of returning home *via* India, Japan, and America, and when in Calcutta was unfortunately seized with his fatal illness.

PROF. L. T. O'SHEA.

LUCIUS TRANT O'SHEA, professor of applied chemistry in the University of Sheffield, who died suddenly from cerebral hæmorrhage on April 18 at sixty-two years of age, was educated at the Grammar School and at Owens College, Manchester, and went to Sheffield in 1880 as assistant lecturer and demonstrator in chemistry at Firth College. In 1890 he became lecturer in mining chemistry, and in 1905 professor of applied chemistry, in the university. For the past twenty years he had specialised in the study of explosives as applied to mining operations, and of the coking of coal in retort ovens. He also did much work on the safety of coal mines, particularly with regard to the effect of the gases given off by the coal and of coal dust on explosions in mines. He was a fellow of the Chemical Society, a member of the Society of Chemical Industry, and hon. secretary of the Institute of Mining Engineers.

Prof. O'Shea published "A Contribution to the History of the Constitution of Bleaching Powder," and "The Retention of Lead by Filter Paper," about the time of the lead-poisoning epidemic in Sheffield more than thirty years ago, and some years later, with Dr. W. M. Hicks, he produced electro-iron of almost perfect purity, which the present writer had the privilege of using for experiments when helping to lay the foundations of theoretical steel metallurgy, for which pure iron was required as a basis for study. He also published "A Note on the Woolwich Testing Station," "A Testing Station for Mining Explosives," and "The Safety of High Explosives, with Special Reference to Methods of Testing."

In 1901 Prof. O'Shea went out to the South African War in command of a detachment of the 1st West Yorks Royal Engineer Volunteers, remained until the declaration of peace, and was given the Queen's medal with five clasps. In 1914 he was made O.C. of the O.T.C., Sheffield University, with the rank of captain in the unattached Territorial Force, and he was an energetic and inspiring leader.

Prof. O'Shea was not able to devote a large proportion of his time to research, but he will be greatly missed for the painstaking work he did in the training of students in chemistry as applied to mining and to the coking of coal, and in the general preparation of fuel for industry.

A. McW.

A MAN who had great influence in the applications of science to the use and convenience of man has passed away in MR. THEODORE N. VAIL, well known to many in England, as well as in

his homeland across the Atlantic. Mr. Vail's life-work was the development of the "Bell" telephone system in the United States, and it is to his personal initiative that the enormous growth of the American Telephone and Telegraph Co., of which he was for many years the president, is largely due. He was a rare combination of the business man, quick to see opportunities and far-seeing in his policy, and the patient, scientific worker. It is not too much to say that the success of the American telephone system, culminating in the achievement of speech from New York to San Francisco, is mainly due to the unremitting attention that he gave to the organisation and prosecution of research, and the technical laboratories that he initiated are the finest in any industrial undertaking. It is pleasant to think that, unlike many workers on parallel lines, Mr. Vail lived to behold the fruit of his labours.

THE death is announced, at the age of eighty years, of DR. JOHN A. BRASHEAR, the founder of the well-known American firm of makers of astronomical and physical instruments. In his youth, while working as a machinist, Dr. Brashear devoted himself to the study of astronomy, and made his first telescope while pursuing this hobby after his working hours. With this instrument he made many observations, as a result of which he contributed articles to the daily Press on comets, etc. These attracted the attention of Mr. William Shaw, whose offer to build and equip for him a good shop for the production of astronomical instruments was accepted. This ultimately developed into the works of the John A. Brashear Co. at Pittsburgh, which turns out instruments that are used in observatories all over the world. Dr. Brashear received the honorary doctorate from Pittsburgh and other universities, and from 1901 to 1904 was acting chancellor of the Western University of Pennsylvania, now the University of Pittsburgh. He was a member of many American and foreign scientific societies, and was a recognised authority on solar phenomena, lunar craters, and other subjects.

MR. JAMES METCALFE, who died on April 12, was born in 1847, and was locomotive superintendent of the Manchester and Milford Railway from 1867 to 1880. He was afterwards managing director of the Patent Exhaust Steam Injector Co., whose injectors are extensively used in locomotives. Mr. Metcalfe was elected a member of the Institution of Mechanical Engineers in 1906.

THE death is announced of MR. FRANK EDWARD PRIEST as having taken place on April 14. Mr. Priest was born in 1860, and was chiefly interested in railways, waterworks, and road and sewerage works. He took a great interest in aeronautics, and at the time of his death he was chairman of Messrs. A. V. Roe and Co., Ltd. He was elected a member of the Institution of Civil Engineers in 1896.

Notes.

FURTHER news from Capt. Roald Amundsen fails to explain his movements. According to the *Times* of April 23, a message has been received in Norway from the wireless station on the Anadir to the effect that the expedition will arrive at Nome, Alaska, at the end of July. Nome is the port Amundsen reached on his accomplishment of the North-West Passage in the *Gjoa* in 1905. Possibly his ambitions include the North-West Passage before starting on his North Polar journey. These two difficult journeys, in addition to the discovery of the South Pole and the not improbable attainment of the North Pole, would be a remarkable record for one man. A start on the polar drift from Bering Strait or Point Barrow entails a longer route than Amundsen had originally intended, so that he may be calling at Nome for extra stores. News of the arrival of Amundsen himself at Anadir needs confirmation.

NOW that political and social conditions are more favourable in the Near East, a certain recrudescence of archæological activity is evident. The recent discoveries of M. Hatzidakis at Mallia, in Crete, have been followed by a further discovery west of Candia. M. Xanthoudides has excavated a Cretan palace, which appears to date for the most part from the end of the Middle Minoan period to the end of the first Late Minoan period. The most important discovery made in the palace was a series of colossal bronze double-axes, measuring several feet in length in some cases. No such axes of this size have yet been found on Cretan sites, and their purpose is for the present obscure. Another excavation by M. Xanthoudides near Candia brought to light some pottery of Early Minoan date of a peculiar type. Similar pottery has been found only at one other site in Crete, and it does not appear to be typically Cretan. In shape the vases found resemble the so-called Minyan ware. In technique they have no parallel in Cretan wares. The detailed publication of both these excavations will be awaited with the greatest interest.

APPLICATIONS for grants in aid of scientific investigations bearing on agriculture are receivable by the Ministry of Agriculture and Fisheries not later than May 15. They must be made upon Form A. 230/1, copies of which are obtainable upon application to the General Secretary, Ministry of Agriculture and Fisheries, 72 Victoria Street, S.W.1.

THE Minister of Health has appointed a Committee to consider and advise on the legislative and administrative measures to be taken for the effective control of the quality and authenticity of such therapeutic substances offered for sale to the public as cannot be tested adequately by direct chemical means. The members of the Committee are:—Sir Mackenzie Chalmers (chairman), Dr. H. H. Dale, Dr. G. F. McCleary, Mr. A. B. Maclachlan, and Dr. C. J. Martin. The secretary is Dr. E. W. Adams, of the Ministry of Health.

THE following have been elected officers and council of the Society of Antiquaries of London:—*President:*

Sir C. Hercules Read. *Treasurer:* Mr. W. Minet. *Director:* Sir Edward W. Brabrook. *Secretary:* Mr. C. R. Peers. *Council:* Sir W. Martin Conway, Mr. V. B. Crowther-Beynon, Mr. H. R. H. Hall, Mr. W. J. Hemp, Mr. A. F. Hill, Mr. C. H. Jenkinson, Sir Matthew I. Joyce, Mr. C. L. Kingsford, Lt.-Col. G. B. Croft Lyons, Prof. J. L. Myres, Lord Northbourne, Prof. E. Prior, Mr. J. E. Pritchard, Mr. H. W. Sandars, Major G. T. Harley Thomas, Mr. R. Campbell Thompson, and Mr. W. H. Aymer Vallance.

THREE important scientific appointments will shortly be made by the British Cotton Industry Research Association, and the council of the association invites applications from qualified candidates. The posts to be filled are those of the heads of the departments of colloid chemistry and physics, organic chemistry, and botany. The minimum salary offered in each case is 1000*l.* per annum. Applications, accompanied by the names of two referees, must be received not later than Saturday, May 22. Forms of application and any further information may be obtained from the Director, British Cotton Industry Research Association, 108 Deansgate, Manchester.

INFLUENZA is abating somewhat in its severity, according to the latest weekly returns of the Registrar-General. The deaths from the disease for the week ending April 17 numbered only 306 for the ninety-six great towns of England and Wales, whilst for the three preceding weeks the deaths were 392, 379, and 332. A similar decrease is shown in the deaths for London, which for the week ending April 17 numbered 101, and for the three preceding weeks the deaths were 131, 124, and 105. The returns also show a decrease in the deaths from pneumonia and bronchitis. The age incidence of the present influenza epidemic resembles somewhat the character of the attacks in 1918 and 1919, which were entirely different, so far as age incidence goes, from previous attacks since 1890. There seems, however, now a tendency to revert somewhat to the former age incidence. In the present epidemic the deaths in London during the last twenty-six weeks numbered 1056, and of these 16 per cent. occurred between the ages of 0 and 20, 36 per cent. between 20 and 45, and 48 per cent. at ages above 45 years. In the virulent attacks of 1918 and 1919 the deaths were about 24 per cent. between the ages of 0 and 20, 46 per cent. from 20 to 45, and 30 per cent. above 45 years, the able-bodied being attacked most severely. The maximum number of deaths in any week in London during the present epidemic was 131, whilst in the summer epidemic of 1918 the deaths in one week numbered 287, and in the autumn of 1918 the deaths from influenza for two successive weeks, November 2 and 9, amounted to 2458 and 2433. For the ninety-six great towns the deaths for the same two weeks in November were respectively 7412 and 7557, against 392 in the week ending March 27 in the present epidemic.

IN *Man* for April Sir W. Ridgeway describes two wooden Maori daggers, part of a collection brought home by the late Col. Honner after the first Maori war in 1840–41. It was at first suggested that these implements were Potuki, or "flax-beaters," and it was doubted whether the Maori did use daggers. But Mr. Henry Balfour has described a bone dagger from the Chatham Islands, and some cultural similarities indicate a link between those islands and New Zealand, especially the Otago district. It is now certain that the Maori did use daggers made of wood and bone. As regards the Potuki, there is a class of beautifully carved examples which can never have been put to any practical use. Their exact function has not been recorded, but they were, perhaps, signs of dignity in the tribe. Sir W. Ridgeway remarks that the paper mulberry, from which tapa cloth was made, was brought to New Zealand by Maori immigrants. But it did not thrive, and the tapa-beater, so important in the social life of Polynesia, would thus fall out of practical use. "My suggestion is that it retained only a ceremonial significance, and that its parallel straight grooves conditioned the type of decoration which the Maoris subsequently applied to it."

IN the Journal of the Manchester Egyptian and Oriental Society for 1918–19, recently published, Mr. W. J. Perry discusses the significance of the search for amber in antiquity in connection with the megalithic problem. He supposes that the amber used for decorative purposes in the Mycenæan age may have been found in the Adriatic. It is not easy, however, to see why it should have been so readily adopted as a form of wealth, as it does not possess the attractiveness of gold and pearls. Mr. Perry suggests as an explanation of its value that amber, a solidified resin, may have been associated with the productions of certain trees venerated in Egypt as the source of resinous substances used in mummification and other death-rites. As a further explanation he refers to the Chinese use of jade and gold, supposed to convey vitality to those who consumed them. "In the case of the Chinese, whose civilisation can be accounted for on the hypothesis of a cultural movement across Asia from goldfield to goldfield, the desire for life, health, and immortality has played an important part in the production of philosophical systems, and thus it is possible that their civilisation itself owes its existence to that instinctive process." The theory is certainly ingenious, but the evidence in its support is still scanty, and the analogy of Chinese or Egyptian beliefs with the search for amber in Europe must be accepted with some caution.

THE trade routes of the British Empire in Africa is the subject of a paper by Mr. G. F. Scott Elliott in the Journal of the Royal Society of Arts for April 2 (vol. lxviii., No. 3515). Mr. Scott Elliott approaches the problem of future rail and steamer routes from a geographical point of view. He emphasises the location of the plateau regions in Central Africa, each of which above 5000 ft. is a possible centre for European settlement, civilisation, and trade. The problem as he sees it is to link these interior regions with British seaports by lines through British territory. He discusses at length the possible routes for railways linking Lakes Nyassa, Tanganyika, Victoria, Edward, and Albert. These lines, with the construction of a railway from Kashitu. on the Bulawayo-

Katanga line, would complete a Cape-to-Cairo route within British territory.

THE annual report on the Nile gauges and rainfall of the Nile Valley ceased publication during the war, the last number being that for 1912, published in 1914. The work has now been transferred from the Survey Department to the Ministry of Public Works, which publishes the records of the gauges for 1913 to 1918 as Physical Department Paper No. 1. In order to reduce the number of data, five-day means are given for twenty representative gauges between the delta barrage and Entebbe, on Lake Victoria. Tables are also given of monthly means for each of the six years, and the actual discharges on certain days at several stations on the main Nile and Blue Nile. These discharges were measured by the current meter, which Mr. H. E. Hurst, the author of the report, calculates has a probable error of not more than about 3 per cent.

Two papers published recently by the Ministry of Agriculture and Fisheries (Series II., Sea Fisheries, vol. iv., Nos. 1 and 2) deal with the method of determining the age of fishes by inspection of the scales. It is well known that the material of the latter structures is laid down in more or less regular layers, and that there are differences between the substance deposited in the warmer, and that laid down in the colder, months. By counting these rings, then, an estimate of the age of the fish can be made. The method is not applicable to all scale-bearing fishes, and there has been much discussion as to its trustworthiness. In the first of the papers to which reference is here made Mr. R. E. Savage describes the structure of various scales as elucidated by special reagents and studied under polarised light. In the second paper Miss R. M. Lee has made a critical review of most of the important memoirs dealing with scale-markings, and subjected selected series of measurements to mathematical tests. Her general conclusions are that, with certain precautions, the method is trustworthy.

THE climate and weather of the Falkland Islands and South Georgia is the subject of a memoir compiled by Mr. C. E. P. Brooks, and published by the Meteorological Office as Geophysical Memoir No. 15. The Falkland Islands observations are all from Cape Pembroke lighthouse with the exception of a few discontinuous series from Port Stanley. The Cape Pembroke records date from the visit of the *Scotia* in 1903, when Dr. W. S. Bruce and Mr. R. C. Mossman started observations there in connection with their records in the Weddell Sea. The scanty South Georgia records are the result partly of various scientific expeditions, but are mainly due to the enterprise of the Argentine Fishery Co. in Cumberland Bay. Summaries of all available data, including those previously published, are given in the memoir.

THE Danish Meteorological Institute has published its issue for 1919 on the state of the ice in Arctic seas. As usual, the publication is in both Danish and English, and is well illustrated with charts. Information was scarce from the Beaufort and Bering Seas, Baffin Bay, and the western part of Davis Strait. In Spitsbergen seas the state of ice was about normal; the pack-ice off the west coast in April and May disappeared in June, and did not return throughout the summer. The ice in the fjords did not break up until May, which is later than usual and two months later than this year. The coasts of Iceland were singularly free from ice throughout the year except for a few days on the north-east in spring, and again in summer. Icebergs on the Newfoundland banks were normal in number and distribution. The Kara Sea, as usual, was navigable in the south and east in September, but there is no information for earlier summer months.

THE attention of systematic students of the Arachnida may advantageously be directed to J. Hewitt's "Survey of the Solifugæ of South Africa" (Ann. Transvaal Mus., vol. vii., part 1, 1919), in which clear generic and specific diagnoses are illustrated by structural drawings and by a series of excellently reproduced photographs. E. A. McGregor's paper on the "red spiders" (Tetranychi) of America (Proc. U.S. Nat. Mus., vol. lvi., 1919) is another recent arachnological publication of importance.

A CONTRIBUTION of importance to Cetacean embryology has been made by Dr. F. E. Beddard, who describes (Ann. Durban Mus., vol. ii., part 4, 1919) two embryos of the sperm whale of an earlier stage than has hitherto been observed. The smaller, measuring only 114 mm. in length, has the relatively short head flexed ventralwards, so that its long axis is almost at right angles to that of the body, while the lower jaw projects beyond the upper; the tail-fin is narrow and ovate in form.

IN a memoir on "The Theoretical Determination of the Longitudinal Seiches of Lake Geneva" (Edin. Roy. Soc. Trans., vol. lii., 1920, pp. 629–42), Messrs. Doodson, Carey, and Baldwin have applied Proudman's general solution (Lond. Math. Soc. Proc., vol. xiv., p. 240) to the particular case of Lake Geneva. The dimensions of the lake along thirty-one sections being obtained from Hornlimann and Delebecque's map, the durations of the first three periods were found to be 74·45, 35·1, and 28 minutes. According to Forel's observations (with a slightly different zero-plane), the period of the uninodal oscillation is 73·5 minutes, and of the binodal oscillations 35·5 minutes. The positions of the nodes of the uninodal and binodal oscillations are also determined theoretically, and agree approximately with those found experimentally, although, as the authors remark, the exact determination of nodes by observation is very difficult. Would it not be possible to test the latter by observing the reflections of the setting sun from the east end of the lake? Three definite reflections were once seen from such a position by the writer of this note.

THE Journal of the Queckett Microscopical Club (vol. xiv., November, 1919) contains an interesting contribution by Dr. Hamilton Hartridge on microscopic illumination, in which the question of the supposed advantages of so-called critical illumination (which consists in accurately focussing an image of

the actual source of light upon the object under examination) is carefully examined. The well-arranged and conclusive experiments described by the author lead to an unconditionally negative answer which will not surprise those who are familiar with the theory of microscopic image-formation, but the results, being experimental, may put an end to the barren discussions on this subject by practical microscopists. A very neat and compact arrangement for the efficient and perfectly controlled illumination of objects in accordance with the results of the investigation is described. Some of the theoretical views in the first part of the paper are not acceptable. Whilst it is true that the usual methods of illumination do not strictly realise the assumptions underlying Abbe's theory, it is surely not open to question that the *theoretical* work and the rare *theoretical* calculations of images have always been carried out in accordance with the theory. The statement that if the ideals of critical illumination were realised, then resolution would be destroyed, is quite untenable, for as that ideal is to make the object behave as if it were self-luminous, the statement amounts to claiming that a self-luminous object—say a white-hot one—could not give a distinct image, which is absurd.

WE have received the fourth report (for 1916) of the seismological observations at De Bilt, Holland (Konink. Nederl. Meteor. Inst., No. 108, 1918, pp. 1–102), in which are given full details of the records obtained from horizontal motion seismographs of Galitzin and Wiechert and a pair of Bosch horizontal pendulums, as well as a summary of the results from other observatories of the more important earthquakes. From this report we learn that the munitions explosion at Faversham on April 2, 1916 (see NATURE, vol. xcix., 1917, p. 250), was registered by the Wiechert and Galitzin pendulums at De Bilt. The effects of the air-waves of this explosion were widely manifested in Holland, especially in the western districts, by the shaking of doors, windows, and pictures, as if by a slight earthquake.

ONE of the strongest earthquakes felt in Porto Rico since the European occupation occurred on October 11, 1918, the official Report of the Earthquake Investigation Commission (Washington, 1919), by Prof. H. F. Reid and Mr. S. Taber, having recently been published. The approximate position of the epicentre is given as 18° 30′ N. lat., 67° 20′ W. long., in the north-east portion of Mona Passage, and the time of occurrence, within a very few seconds, at 2h. 14m. 38s. p.m. (Greenwich mean time). The earthquake was followed after a few minutes by a sea-wave which reached a height of about 4½ metres above mean sea-level along the north-west coast of Porto Rico, the first movement of the water, wherever seen, being one of withdrawal. The epicentre lies along a deep submarine valley, the slopes of which are so steep that they must be regarded as the result of faulting. During the last half-century the north-west coast of the island has been noticeably subsiding, and the authors attribute the earthquake and sea-wave to a vertical displacement near the head or on one side of the submarine valley.

Our Astronomical Column.

ECLIPSE OF THE MOON.—There will be a total eclipse of the moon on the night of May 2–3. The following are the Greenwich times of the various stages:—

Moon enters penumbra ...	May 2,	10.49 p.m.
Moon enters shadow		12.0 mid.
Beginning of total eclipse	3,	1.15 a.m.
End of total eclipse ...		2.27
Moon leaves shadow		3.41
Moon leaves penumbra		4.53

At Greenwich the moon rises on May 2 at 7.5 p.m. and sets on May 3 at 4.34 a.m. The whole of the phases of the eclipse will thus be visible.

During some lunar eclipses the disc of our satellite has remained fairly bright, while at others it has been scarcely visible. If atmospheric conditions are favourable, observations of the character of the shadow on this occasion might be made and, possibly, photographs taken. During the lunar eclipse of July 4, 1917, observations made at the Bordeaux-Floriac Observatory showed that, throughout totality the north edge of the moon seemed brighter than the south.

MARS AND WIRELESS SIGNALS.—It is regrettable that in these days, when results of great interest concerning solar and stellar physics are continually being reached, the public should have its attention concentrated upon sensational assertions, such as the Porta planetary scare last December and the suggestion of wireless signals to or from Mars which is now under discussion in the daily Press. Leaving aside the physical difficulties of such communication—which, though considerable, are perhaps not insuperable—a very little consideration suffices to show the utter improbability, closely approaching to impossibility, that the idea of signalling should be mooted simultaneously on the two planets. On any view as to the development of the planetary system, the periods when Mars and the earth pass through corresponding stages would be likely to be separated by millions of years. The suggestion that the Martians have kept up the practice of signalling at every opposition through such a period as this, in the patient hope that they might one day be answered, makes too strong a demand upon our credulity.

THE APRIL METEOR SHOWER.—The weather was moderately fine at the time the Lyrids were expected, and a fair number of them were visible. The best night seems to have been that of April 21, when the sky was generally clear and the maximum abundance occurred near midnight. The phenomenon was observed by Miss A. Grace Cook at Stowmarket, Mr. S. B. Mattey at Plumstead, S.E., Mr. C. P. Adamson at Wimborne, Mr. W. F. Denning at Bristol, and others. The Lyrid meteors formed about one-half of the total number visible on the nights of April 19, 20, and 21, and nearly all of them left streaks. They moved with moderate velocity, being decidedly slower than either the Leonids or the Perseids. As regards brightness they were much above the average, and some fine ones were recorded on the dates mentioned.

THE WASTING OF STELLAR SUBSTANCE.—This is the title of a paper by Prof. F. W. Very in *Scientia* for April. It will be remembered that Prof. Eddington made the suggestion in the *Observatory* last September that the immense duration of the radiation from the stars might be explained by the annihilation of some of their component atoms through collision, and the consequent liberation of their stores of energy.

Prof. Very states that he made a similar suggestion many years ago. He conjectures that great gaseous nebulæ, such as that in Orion, are the synthetic laboratories where matter is being built up; he applies the idea to the Russell sequence of giant and dwarf stars, supposing that the loss of mass (contrary to Prof. Eddington's suggestion) is a large fraction of the whole initial mass, so that the dwarfs, on his view, are stars not merely of smaller diameter and greater condensation, but also of small mass. The increase of velocity with advance of spectral type would thus receive an explanation.

Map-making in India.

THE Report for the year 1915-16 (vol. x.) of the Records of the Survey of India (printed at the office of the Trigonometrical Survey, Dehra Dun, 1917), which has lately come to hand, is somewhat belated. The price of it alone would indicate this, viz. "four rupees or 5s. 4d."; which does no justice to the present value of the rupee. It is in other respects a new departure. There is no preface, and we look in vain for the usual summing-up of the scientific results of the year's work by the Surveyor-General, Sir Sidney Burrard, who, for that matter, has ceased to direct the Department and retired to a well-earned rest. On the whole, it is a dry record of useful progress in the work of map-making, supplemented by long tables of the results of scientific observation, which surely, if they are of any use at all, should be published in such an up-to-date form as to compare readily with the work of other observers elsewhere whose researches may lead them into the same scientific fields. There is no narrative or detail explanation showing how the results recorded have been attained; no excursions into the realms of geography to lend a flavour of romance to the volume; and no new theories or startling discoveries to save it from the familiar atmosphere of dry official dullness. It is, of course, not meant to be amusing, but it might easily be made more interesting. One unusual and redeeming feature it does indeed contain. There are seven most excellent photogravure portraits of those gallant officers of the Department who fell in the service of their country. They are so good that one cannot but hope that they exist otherwise than in this official environment, and have already become a permanent and honourable feature in the headquarters' offices of the Indian Survey.

The actual progress of mapping for military purposes under the difficult conditions of the war period, when so many men were absent on duty in the fields of France, Mesopotamia, and elsewhere, appears to have been most satisfactory during that busy time. The Punjab surveys extended into Kashmir, and included a great deal of revision on the one-inch scale as well as certain areas on four inches to the mile. This feature of variety in the scale of mapping is common to all the topographical parties, and is a most encouraging sign that the scale is now adapted to the quality of the district surveyed far more freely than used to be the case. Formerly, there is no doubt, much money was wasted over unnecessarily large scale work in districts which had no possible military significance and not much geographical importance in any sense. Practically the topographical surveys are scattered all over India, from the Punjab to Madras and Burma. An examination of cost rates is interesting, for it does not indicate that the cost has greatly altered during the last twenty years. Here again everything depends on the physical characteristics of the district. From 7·6 rupees per square mile in the Punjab (almost entirely revision) to 50·7 rupees in Burma is certainly a most reasonable outlay for the work of the one-inch class, especially when compared with the enormous costs of European mapping on the same scale. The two-inch-per-mile surveys were a trifle more costly (when compared with previous years) than usual, but the surveyors had to face special difficulties in the shape of large areas of dense forest growth.

There is no record of any extension of first-class triangulation, and the scientific branch of the Survey Department seems to have been directed towards the completion of "fore and back double levelling of precision" in the Punjab and the United Provinces, together with the usual programme of tidal and magnetic observations. It is interesting to note the generally increasing accuracy of tidal predictions, although certain errors seem to require explanation. For instance, there were five predictions at Moulmein which were more than thirty minutes wrong. Why? The tabulated magnetic results show that great disturbances occurred in 1915, particularly in the month of June; and on August 29, 1916, the seismograph was dislocated by the violence of its action in recording an earthquake shock. The report, however, says nothing as to the probable location of that shock. It would be interesting to know more about it. An ingenious instrument for calculating attractions, which the designer, Mr. J. de Graaff Hunter, calls an "integrator," is illustrated by photogravure in the report, and this is indeed the one new feature in it which will probably attract most attention from men of science.

The final record of publications by the Survey of India can be best studied by an examination of the index charts which form the appendix. Progress with the 1/M (one-millionth) Maps of the World Series is very satisfactory. It is this class of geographical mapping which has formed the basis for the Peace Conference boundary delimitations, and in their preparation India is working hand-in-hand with the Royal Geographical Society and the Geographical Section of the War Office.

Vol. xiii. of the Survey of India Records, which is issued as supplementary to the general report of 1917-18, brings the topographical records of the Department to a later date than the above. It deals with the same distribution of parties working on original, revision, or supplementary surveys in much the same fields, and denotes good progress at reasonable rates, but for purposes of comparison a more detailed summary is wanted of the amount of survey completed in each class and a few notes on its character and cost by the Officiating Surveyor-General, Col. Ryder, R.E. The geodesic and scientific operations are summarised in part ii., and in the appendices will be found useful reprints from the Journal of the Royal Geographical Society (March and October, 1918) on the problem of the Himalayan and Gangetic troughs, containing the views of such scientific experts as Sir Sidney Burrard and Mr. R. D. Oldham on this most interesting subject. A feature in the report which attracts attention is the distribution of Survey detachments (with the consequent weakening of field parties) amongst artillery practice camps, presumably for the same purpose of range determination as that which absorbed such a large and expensive staff of surveyors under R.E. direction during the later years of the war. This leads one to ask whether the gunners could not be trained to carry out such special surveys for themselves.

T. H. H.

Melanism in British Lepidoptera.

MELANISM has long been a subject of special interest to British entomologists owing to the rise and spread of melanic varieties in many British species of moths and butterflies, such groups as the Geometridæ showing many examples. Records of melanism go back at least to 1850, when the dark variety *Doubledayaria* of *Amphidasys betularia* appeared near Manchester. It afterwards spread until it became the prevalent or exclusive form in Lancashire and the Midland Counties, extending also to the Continent in later years. The earlier naturalists' point of view (as represented by the writings of Tutt and of Porritt) concerning its causation, related it to the progressive darkening of the background in the neighbourhood of cities as a result of industrialisation. When this explanation was found to be inadequate, moisture was added as a cause of melanism; and Tutt concluded that moisture would darken the surfaces of rocks in rural districts just as smoke darkens surfaces in urban areas, natural selection progressively favouring darker forms which habitually rested on such darkened backgrounds.

In a recent consideration (*Journal of Genetics*, vol. ix., No. 3) of melanism, based on extended observations and breeding experiments in Yorkshire, Mr. J. W. H. Harrison discards the older hypothesis and proposes a new one. This is based on a modification of the insect's metabolism by its feeding upon substances more or less impregnated with chemicals derived from the smoke. It is pointed out that certain melanic areas, such as the vicinity of Middlesbrough, Newcastle-upon-Tyne, and Moray Firth, are among the driest in the country, having a rainfall of 25–28 in. Also, in such species as *Boarmia repandata* and *Oporabia dilutata* the melanic varieties are confined to the towns, while the type occurs in the surrounding country. The melanic forms of different districts, moreover, differ from each other, showing that they have originated locally and irrespective of each other.

Observations showed that an increase in melanism was accompanied by a striking decadence of cryptogamic plants, especially mosses, liverworts, and lichens, many species having quite disappeared from affected areas owing to smoke contamination. This effect on vegetation, and also the degree of melanism, is found to diminish as one leaves the town.

Mr. Harrison compares melanism to such a condition as alkaptonuria in man. The latter condition is known to be inherited, and may be considered a chemical mutation in which the alkapton is not decomposed owing to the absence of a certain enzyme. He suggests that the taking in with the food of small quantities of such salts as KCl, NaCl, and MnSO, present on the foliage in urban areas would lead to an increase in the amount of tyrosinase present, and so to an increased deposition of melanin, since the activity of various enzymes is increased by the presence of small quantities of these salts. The same interpretation is extended to melanic forms on coasts and islands, where the vegetation is impregnated with similar salts from the sea spray.

It is known that in many cases melanic varieties behave in inheritance as simple Mendelian dominants to the type (*e.g.* Onslow, *Journal of Genetics*, vol. ix., No. 1, on the melanic variety of *Boarmia* (*Tephrosia*) *consonaria*). In crosses with species of Oporabia, however, the author obtained a blend which remained true for two generations, and is interpreted as a gametic blend, the melanism being of a perfectly continuous type. Also, when the hybrids between *O. autumnata* and *O. filigrammaria* were crossed back with the parent forms, a blend resulted. In the F_2 of the cross, however, a "pseudo-segregation" was observed, which is likened to the behaviour in *Oenothera Lamarckiana*. Many writers have suggested such a relation between hybridisation and mutation.

In this interesting and manifold study the author has discarded an original anti-Lamarckian bias, and concludes that various cases, such as the food instincts of *O. filigrammaria* and the period of emergence in a pinewood race of *O. autumnata*, are only explicable as true Lamarckian effects. Natural selection is believed to lead to the genesis of local races, "limiting the range of variation by the elimination of genetical strains less protected in any given habitat."

The haploid chromosome numbers are determined for *O. dilutata*, *autumnata*, and *filigrammaria* as 30, 38, and 37 respectively, and the behaviour of the chromosomes in meiosis furnishes a basis for a further interpretation of the hereditary phenomena.

University Developments at Manchester.

THE University of Manchester is appealing for the comparatively small sum of 500,000*l.* in order to enable it to maintain its present activities effectively and to develop new features. These embrace not only additional buildings and equipment urgently required for the extension of the School of Medicine, especially in the departments of pharmacology and pathology, and for advanced scientific study and research in other important spheres of the University's many-sided work, but also a large increase in the professorial staff, including new professorships in social and political science, physiological chemistry, law, mathematical physics, and French. The present Department of Commerce, established in 1904, is stated to be hopelessly inadequate to the needs of a great commercial centre such as that of south-east Lancashire, and demands, if it is to serve its purpose worthily, a considerable strengthening of its teaching staff. The University has recently established a new degree, namely, the doctorate in philosophy (the Ph.D. degree), granted upon a course of advanced study and research, which will necessarily involve a large expenditure in staff and equipment.

The University is committed to an expenditure of a sum of 171,000*l.* in respect, among other items, of the building and equipment of the new arts building, where it is intended to house the subjects of languages, literature, history, and philosophy, the endowment of new chairs, the reconstruction and equipment of scientific departments, and the provision of women's hostels. It is further contemplated to set up a wide extension of extra-mural teaching so as to bring the influence of the University more closely in touch throughout its wide area with the needs and aspirations of working people by means of extension lectures and systematic three-year evening courses of tutorial classes.

Already in response to the appeal of the University a sum of about 160,000*l.* has been raised, and it ought not, having regard to the population and wealth of the area the University serves, to be difficult to secure the desired sum, and even more. With the view of inducing a large number of people of small means to participate in the effort to raise the money required, a novel scheme has been launched in the form of a prospectus, such as that issued on behalf of limited liability companies, entitled "Lancashire Development, Unlimited, The University of Manchester," inviting subscriptions for new capital to the extent of 500,000*l.*, divided into 425,000 cumulative participating bonds of 1*l.* each and 1,500,000 people's

bonds of 1s. each, the interest upon which will be found in the enrichment of the whole life of the people served by the work of the University. The faculty of technology carried on in the Municipal College of Technology is also issuing an appeal for 150,000l., more than half of which has already been subscribed, for the extension of its building and for new equipment. The great and lasting benefit of the work of the University ought to rouse the active sympathy of the numerous municipalities and district councils, together with that of the County Council itself, and to induce these bodies to levy a rate which, if as low as ½d. in the pound, would annually produce a sum equal to the interest upon the half-million it seeks to raise.

Courses on the History of Science.

GERMAN and American universities long ago recognised the importance of the history of science as a subject of academic study. In British universities the subject is only just beginning to receive attention. In the University of London last year the Faculty of Arts passed a resolution in favour of including the history of science among the subjects for the B.A. degree, and, although the Senate has not yet dealt with the question, the inclusion of the subject in the curriculum for the new diploma in journalism has helped to advance matters. University College undertook to provide the necessary courses. During the first and second terms of the session 1919–20 Dr. Wolf delivered a course of elementary lectures on the general history and development of science until the end of the eighteenth century. During the present (summer) term Sir W. H. Bragg and others will deal with the history of physical science during the nineteenth century, and Dr. Singer will lecture on the history of medicine. A more elaborate programme will be provided next session. Sir W. H. Bragg and Dr. Wolf will repeat their courses, Prof. J. P. Hill and Dr. Singer will deal with the history of the biological and medical sciences, Prof. Filon will lecture on the history of astronomy, and Mr. Wren on the history of mathematics. The history of other sciences will also be dealt with as opportunity offers.

The primary aim of the elementary courses on the history of science is to provide an essential part of the history of culture. The modern treatment of history is marked by the attention paid to the daily life and habits of the people, as well as to the romance of Court life and the adventures of warriors. The kind of houses which our forefathers inhabited, the kind of dress they wore, and similar matters are receiving due attention in order to fill in the historic picture. All this is as it should be, but the picture can scarcely be complete without the realisation of the mental make-up of the ages, especially so in view of the important *rôle* played by scientific ideas in carrying forward the torch of civilisation.

Over and above its value as an essential part of human history, a course on the history of science should also have the moral and disciplinary value of inculcating a scientific frame of mind—the kind of attitude on which the future of mankind will depend more than ever now that the age of faith seems to be a thing of the long ago.

Such are some of the benefits that may be expected even by those who are not, and do not intend to be, scientific workers, to say nothing of the scientific knowledge which even such students are bound to acquire in following an elementary course on the history of science. More advanced courses for scientific students can scarcely fail to confer the additional advantage of illuminating the methods and results of the makers of science, and so stimulating the latent originality of the student of science.

Marine Biological Structures and Functions.

VOL. XIII. of Papers from the Department of Marine Biology of the Carnegie Institution of Washington, which has lately reached us, contains some contributions of considerable interest. Dealing with gland-cells of internal secretion in the spinal cord of the skates, C. C. Speidel describes large irregular cells of peculiar structure present to the number of some hundreds in the anterior horn. The nucleus is lobular and branched, and the cytoplasm of the resting cell is homogeneous, but in active stages granules of a protein substance are formed in it and discharged into the tissues of the spinal cord, where they persist for some time. These cells develop from neuroblast tissue, and cells homologous with them have been found in various other fishes. The author discusses their function, and concludes that they are gland-cells of internal secretion. He is unable to find that they are necessary to the life of the skate, or to show what their function may be. In a paper on the spermatophores of *Octopus americana*, G. A. Drew shows that these structures, while they are built on a similar plan to those of the squid, are adapted to act quite differently, being less complicated, under less tension, and suited for less rapid service, in correspondence with the less active life of the species. H. L. Clark finds in the distribution of littoral Echinoderms of the West Indies evidence of a much closer relationship between that region and the western coast of tropical America than between it and the Mediterranean, while the fauna of Tobago contains an element derived from the Brazilian coast. Studies on the chemistry of light production in luminous organisms by E. N. Harvey reveal that the substance formerly called photophelein by that author includes two bodies, one—luciferin—oxidisable by luciferase with production of light and formation of oxyluciferin, which can again be reduced to luciferin, the other—protophelein proper—assisting in the promotion of the luciferin-luciferase reaction. E. W. Gudger describes the ovary of *Felichthys felis*, the gaff-topsail catfish, the male of which carries the eggs and larvæ in his mouth.

The Propagation of Flame in Gaseous Mixtures.

ALTHOUGH the large-scale experiments for which the Home Office Experimental Station at Eskmeals was designed have been discontinued since the outbreak of the war, the laboratories have continued to do good work under the direction of Dr. R. V. Wheeler, the chief chemist. In addition to Dr. Wheeler's own researches on the initiation of flame and its propagation through gaseous mixtures, Mr. W. Payman, a member of his staff, has recently published in the Journal of the Chemical Society a series of papers on the propagation of flame in complex gaseous mixtures (vols. cxv. and cxvii.).

Mr. Payman has determined the upper and lower "limits" of methane that will just propagate a flame along a horizontal glass tube 2·5 cm. in diameter when mixed with an atmosphere containing oxygen and nitrogen in which the oxygen varies from 13·7 to 100 per cent. He finds the speed of such flames

almost identical, on the average 20 cm. per sec., the highest speed being measured when the oxygen was 21 per cent. as in air. The same speed was found for the "lower-limit" mixture of all the other paraffin vapours up to pentane when mixed with air.

The "lower-limit" speed of carbon monoxide is also the same, but with hydrogen and air the speed at the lower limit is much slower (10 cm. per sec.), probably on account of the small size of the flame, which does not nearly fill the tube, though it travels to the end.

Mr. Payman next measured the speed of the uniform rate of the hydrocarbons from methane to pentane (when added in different proportions to air) along the same horizontal glass tube. The fastest uniform rate for methane was given by the mixture containing 9·52 per cent. of methane, viz. 66·6 cm./sec. For propane, butane, and pentane the fastest rate was in each case between 82 cm. and 83 cm. per sec.

Then, by mixing together mixtures of the several paraffins which had the same speed, it was shown that all the mixtures had the same speed except just near the maximum or the extinction point, and this gives us a simple means of calculating the values for any combination of paraffins in air.

In a third paper the speeds of the uniform movement in mixtures of carbon monoxide and air are recorded. The rate increased as the amount of water-vapour rose, *e.g.* when a mixture in equal volumes was saturated with steam at 10° C. The rate was 60 cm./sec., and when saturated at 17° C. 79 cm./sec. The mixture in equal volumes also gave the quickest speed at constant temperature, although the percentage for complete combustion is only 29·5 per cent. The uniform speeds for different mixtures of carbon monoxide with hydrogen and with methane were also determined and compared with the calculated speeds.

In the concluding paper Mr. Payman describes his experiments on the uniform rate of flame in mixtures of methane and of hydrogen with atmospheres richer in oxygen than ordinary air. When methane is mixed with pure oxygen the mixture which gives the fastest initial rate is the theoretical mixture for complete combustion with 33 per cent. of methane to 66 per cent. of oxygen; whereas in the propagation of the explosion-wave the fastest mixture is that in which the gases are in equal volumes. Although the uniform movement of flame in the mixture containing 33 per cent. of methane is faster than that in a mixture containing more methane, the author's photographs show that the explosion-wave is more quickly set up in the latter. The abrupt physical change in the mode of propagation seems to be accompanied by an abrupt change in the chemical reaction.

These papers form an interesting contribution to our knowledge of the propagation of flame by "conduction."

University and Educational Intelligence.

Edinburgh.—His Majesty the King has graciously consented to lay the foundation-stone of the University buildings on the new site of 115 acres at Craigmillar on the occasion of the Royal visit to Edinburgh in July next.

Acting on the recommendation of a special committee recently appointed to consider the question of the German chair, the University Court has resolved that no person be appointed professor of German who is not of British nationality and British parentage, and that, in view of the special circumstances of the case, no appointment to the chair be made at present, but that the present lecturer be retained.

Dr. G. L. Malcolm Smith has been appointed as whole-time assistant in clinical medicine, and Mr. John Anderson as lecturer in logic and metaphysics.

Dr. Robert Kidston has presented to the geological department a collection of Mesozoic fossil plants. The forestry department has received from the Director of the Royal Scottish Museum, on loan, a collection of forestry exhibits, and from the Forest Research Officer of the Federated Malay States and the Chief Conservator of Forests, Dominion of Canada, prepared samples of commercial woods peculiar to these countries.

Prof. H. J. W. Hetherington, of the University College of South Wales, Cardiff, has been appointed to the principalship of Exeter University College in succession to Mr. A. W. Clayden, resigned.

Notice is given by the Royal College of Physicians of London that the next examination for the Charles Murchison scholarship in clinical medicine will be held on Monday, June 14, and following days. The scholarship is of the value of twenty guineas, and tenable for one year. Intending candidates must send their names and other specified particulars by June 1 to the Registrar of the College, Pall Mall East, S.W.1.

At the request of the Ministry of Labour, and with the co-operation of the Rubber Growers' Association, a six months' course of training in the appropriate sciences has been arranged at Birkbeck College to enable ex-Service men to obtain the requisite knowledge to fit them for positions on the great rubber and tea plantations. The course includes training in chemistry, botany, geology, entomology, and simple mechanics, with some knowledge of the care of machinery and book-keeping.

The League of Nations Union is organising a summer school, to be held at Kempsey School, near Worcester, from Saturday, July 31, to Saturday, August 7. The school is open to both men and women. Applications for admission, which will be considered in the order in which they are received, must reach the League of Nations Union, 22 Buckingham Gate, S.W.1, by June 15. The main object of the summer school is to train those likely to make efficient leaders of study circles.

The London County Council will shortly proceed to the appointment of the principals of its first group of twenty-two compulsory day continuation schools to be established under the Education Act, 1918. These appointments will be the first of their kind in London, and will be of more than ordinary interest. The type of pupil to be dealt with is one that hitherto has, for the most part, failed to take advantage of educational facilities after leaving the elementary schools. The Act makes great demands on the commercial and industrial world, and it will devolve on the principals of these schools to cultivate close relations with business men and employers, and to secure their cordial co-operation. The success of this great new experiment in national education depends in considerable measure on the sympathy and assistance of the business world. The position of principal will require of its holder administrative ability, good scholastic attainments, and marked personality. The outside-school activities will have to be fostered in every way, so that, with shorter hours of labour, the increased leisure may be utilised to the fullest profit, not only of the individuals, but also of the community. The work should make a strong appeal to those interested in the social welfare side of education. Advertisements inviting applications for these positions are now appearing in the public Press, and forms of applica-

tion can be obtained from the Education Officer (T/3), L.C.C. Education Offices, Victoria Embankment, W.C.2.

THE MARQUESS OF CREWE, chairman of the governing body of the Imperial College of Science and Technology, was present, with other distinguished guests, at the ninth annual dinner of old students of the Royal College of Science on Saturday last, April 24. Sir Richard Gregory, president of the Old Students' Association, who occupied the chair, in proposing the toast of the governing body, said that the time had come for a national survey of the conditions and requirements of university and higher technical education in this country, so that a comprehensive view could be taken of the problem as a whole, existing deficiencies discovered, and adequate educational facilities provided in all areas. The Imperial College would take an important place in any national scheme which might result from such a survey. Lord Crewe, in responding to the toast, said that the college was not content to be merely a school of any university, however distinguished. Though there was in this country no precedent for a technical university, there was, on the other hand, none for a population of eight millions, which was the population of Greater London, with but one university to serve all purposes. The problem of the reorganisation of the University of London was quite enough in itself, without involving the infinitely more difficult task of trying to combine in some way the activities of the University and of the Imperial College in one entirely unprecedented unit. At any rate, the governors of the Imperial College had made up their minds that the problem had to be solved in a way which assured their practical independence. Sir W. H. Bragg spoke of the increased interest, due mostly to the war, now taken in scientific studies, resulting in overfilled laboratories in university institutions and insufficient instructors. Mr. Herbert Wright gave instances of purely scientific investigations at the college which had proved of great practical value, and Prof. J. C. Philip referred to the steps being taken to provide a worthy war memorial to old students. Prof. H. E. Armstrong, proposing the toast of "The Guests," paid a tribute to the men of science whose work contributed so largely to success in the war; and Sir Richard Glazebrook, in responding, referred particularly to the work of Mr. L. Bairstow, Dr. G. W. C. Kaye, and Mr. F. E. Smith, old students of the college, at the National Physical Laboratory.

Societies and Academies.

LONDON.

Linnean Society, April 15.—Dr. A. Smith Woodward, president, in the chair.—Capt. F. Kingdon **Ward**: Natural history exploration on the north-east frontier of Burma.—R. **Paulson**: Stages in the sporulation of gonidia within the thallus of the lichen, *Evernia prunastri*, Ach. It has for a considerable time been generally accepted that the bright-green spherical gonidium which is common to many lichens, and is referred to in the literature of the subject as Cystococcus, Protococcus, or Pleurococcus, multiplies vegetatively only, while it remains the algal constituent of the lichen thallus. Famintzin (1868), Baranetzki (1868), Woronin (1872), Bornet (1873), and Chodat (1913) state that the gonidia (Cystococcus?) of certain lichens produce zoospores after being isolated from the gonidial layer and afterwards cultivated in, or on, different media. The author has not been able to find that the gonidia of *Evernia prunastri*, and of twenty-three other species of lichens, representing eleven genera, divide vegetatively within the thallus; but in all these cases the reproduction of gonidia was found to be the result of the successive bipartition of the original protoplast of the cell into four, eight, or sixteen separate masses, each of which rapidly develops a cell-wall of its own while within the mother-cell. These daughter gonidia (suppressed zoospores?) ultimately escape as the mother cell-wall becomes diffluent. They exhibit all the characteristics of the parent cell before they are set free.

Royal Anthropological Institute, April 20.—Sir Everard im Thurn, president, in the chair.—R. Grant **Browne**: The races of the Chindwin, Upper Burma. The basin of the Chindwin, in the north-west of Burma, is of exceptional interest to ethnologists on account of the medley of peoples inhabiting it—peoples distinguished from each other by their language and customs rather than by their physical characteristics. They include Burmans, Shans, Tamans, Chins, Nagas, Kachins, and Kadus. These terms denote communities rather than races, for the inhabitants may change from one group to another in the course of a few years. The people of Maukkalauk, for instance, are now regarded as Kachins, but have learnt Shan, and will, no doubt, "become" Shans like their neighbours, and eventually Burmans; but their head-man says they left Assam, where they wore white clothes and spoke some language, of which they have forgotten even the name, when his father was a boy. In contrast to this process of assimilation there are mountain tribes living a few miles apart from each other whose dialects have been differentiated until they have become mutually unintelligible. The more civilised communities owe their language and customs to a succession of dominant races. The Burmese came last. Before them were the Shans, and before these probably the Kadus. There are signs that Kadu, now almost extinct in this area, was once the prevailing language of the riverine tracts.

Royal Meteorological Society, April 21.—Mr. R. H. Hooker, president, in the chair.—**Royal Observatory, Greenwich**: A night sky recorder. The object of the instrument is to supplement the daily sunshine record in so far as it gives an indication of the amount of cloud. The instrument consists of a small camera in a fixed position pointing to the pole of the heavens. The lens is a single component of a doublet of 8-in. focal length and 0·4-in. aperture, working at $f/20$. It is found that the aperture, in conjunction with plates of "ordinary" speed, will give a good record even at full moon. Measurements are made by means of a photographic scale.—Lieut. N. L. **Silvester**: Local weather conditions at Mullion, Cornwall. The author gave a detailed analysis of the local meteorological elements in the order of their importance relative to airship navigation, but remarked that the period under review (approximately one year) was too short to deduce much information of climatological value, though during most of this period the observations were as full and as frequent as the changes of the Service in war-time would permit. Ratios of gradient to surface wind had been computed and analysed from the results of more than 400 pilot-balloon ascents by the one-theodolite method. There was evidence of the marked friction and turbulence affecting the wind near the surface in the vicinity of large buildings, such as airship-sheds. Much useful information relating to the local occurrence of fogs and of unusual visibility had been tabulated; whilst another feature was the collection in tabular form of local signs of approaching bad weather, which should prove of value to the local forecaster.—J. E. **Clark**: The Surrey hailstorm of July 16, 1918. This storm differed from other similar British visitations by the

fortunate absence of much wind and by coming after midnight. The track of serious damage rarely exceeded [illegible] mile in width and was 16½ miles long, the hail beginning at 1.55 a.m. west of Holmwood Station and ending near North Bromley Station, twenty-two miles to the north-east, at about 2.30 a.m. (true time).

EDINBURGH.

Royal Society, March 15.—Prof. F. O. Bower, president, in the chair.—Capt. T. Bedford **Franklin**: The effect of weather changes on soil temperatures. In comparison with the variations of surface temperature, the regular pulsations of temperature in the soil follow well-known laws for amplitude and retardation according to depth, but in these regular pulsations there are fluctuations which occur according to the weather and the state of the soil. If the ratio of the ranges of temperature at the 4-in. depth and the surface be taken as the standard for measuring the heat transfer in the soil, it is found that in a light loam soil this range-ratio varies between 0·19 and 0·42 when active percolation is not taking place in the soil, and between 0·4[illegible] and 0·85 when rain is actually falling or during those long-period weather changes associated with the passage of depressions north of these islands, whether rain falls or not. Heat transfer in soil is thus carried out by both conduction and percolation, and a sandy soil that allows free percolation, with consequent high values of the range-ratio, will heat up quicker in spring than a clay soil which takes up and parts with water only sluggishly. Apart from percolation, the high values of the range-ratio in the south-westerly cyclonic type of weather are particularly valuable in causing rapid rises of soil temperature in spring. A surface layer of frozen soil protects the lower depths from rapid changes of temperature; an average surface temperature of −1[illegible]·0° C. would be necessary to freeze ordinary soil to a depth of 4 in. in one night. Snow is an even more efficient protection; in November, 1919, the air temperature above 4 in. of snow fell to −15° C. without freezing the soil surface or causing any appreciable fluctuation in the temperature 4 in. beneath the surface of the soil.—D. **Ferguson**: Geological observations in the South Shetlands, the Palmer Archipelago, and the Danco coast, Grahamland.—G. W. **Tyrrell**: A contribution to the petrography of the South Shetlands, the Palmer Archipelago, and the Danco coast, Grahamland.—H. H. **Thomas**: Petrographical notes on rocks from Deception Island and Roberts Island (South Shetlands), the Danco coast, and adjacent islands, Grahamland. These papers contained a great many new facts regarding the geology and petrography of the rocks in the islands named lying to the south of South America. In a broad sense, the geological arrangement might be described as a mirror reflection of the arrangement on the South American coast, and it was probable that the two sets of strata were connected by an arc passing east, and then bending round to the south and to the west, but there was no evidence in support of Suess's theory that this arc extended far to the east so as to include the South Georgian group.—Miss C. W. N. **Sherriff**: A class of graduation formulæ.—Prof. L. **Becker**: The daily temperature curve. In this paper the author developed a new mathematical method of treating the variation of temperature, and illustrated it by a discussion of a forty years' photographic record of temperature in Glasgow.

DUBLIN.

Royal Dublin Society, March 23.—Dr. F. E. Hackett in the chair.—Prof. James **Wilson**: The application of the food-unit system to the fattening of sheep. A summary of experiments in fattening sheep was published by Mr. Herbert Ingle in the Transactions of the Highland and Agricultural Society of Scotland for 1910 and 1911. From this it is evident that the sheep differs from the bullock by being better able to consume roots, and, therefore, less dependent upon hay and straw. The sheep is also considerably more economical as a producer of human food; for, while the well-fed bullock of average size—say 9 cwt.—needs from six to seven food units to produce a pound of beef—a food unit is the quantity of any other food which would have the same producing capacity as a pound of barley—a well-fed sheep of average size—say 120 lb.—produces a pound of mutton on five to six food units.

Royal Irish Academy, April 12.—Mr. W. G. Strickland, vice-president, in the chair.—E. **Heron-Allen** and A. **Earland**: An experimental study of the Foraminiferal species *Verneuilina polystropha*, Reuss, and some others, being a contribution to a discussion on "The Origin, Evolution, and Transmission of Biological Characters." In this paper the authors describe normal and monstrous forms of *Verneuilina polystropha*. The species exhibits characteristic dimorphism in a long, tapering test which is megalospheric, and a short test which is microspheric, but in the dwarf variety, *pusilla*, the tapering test is microspheric. Observations on the selection by Verneuilina of fragments of heavy minerals, by mixing crushed gems with the sand in the experimental tanks with which the authors worked, are described. Variation in the shells of *Massilina secans* is also described in detail, one of the most remarkable "monsters" being a perfectly twinned specimen which had added a curved tube at the junction of the shells to form a common aperture; the whole of this abnormal shell was chitinous. In another case a shell was entirely chitinous except the terminal chamber, which was perfectly and normally calcareous. Further instances of shells combining the characters of two distinct genera—such as have been recorded in former papers by these authors—are given, and the opinion is expressed that the accepted systems of classification of the Foraminifera, founded as they are on the shape and material of the test, must be regarded as largely artificial and unscientific.

PARIS.

Academy of Sciences, March 29.—M. Henri Deslandres in the chair.—G. **Bigourdan**: The observatory of J. S. Bailly at the Louvre.—Prince Albert de **Monaco**: Stray mines in the North Atlantic. A chart is given showing the positions of sixty-eight mines located between November 7, 1918, and February 9, 1920. The predictions by the author in two earlier communications have been fully confirmed.—A. **Rateau**: Some considerations on flight at very high altitudes and on the use of a turbo-compressor. An adverse criticism of a recent communication on the same subject by M. Villey.—P. **Vuillemin**: The growth of fungi discovered in the human nail by Louis Jannin.—G. **Julia**: Families of functions of several variables.—H. **Mineur**: Discontinuous solutions of a class of functional equations.—B. **de Fontviolant**: The strength of circular arches.—F. **Kromm**: A star with a large proper motion. The star B.D. +9·2636°, 9·1 magnitude, has an annual proper motion of nearly a second of arc.—G. **Sagnac**: Newtonian light radiation and the zones of silence in damped wireless telegraphy signals.—M. **Pauthenier**: The ratio of the absolute retardations in Kerr's phenomenon.—M. **Lemarchands**: Study of the reactions of the metallurgy of zinc.

Zinc oxide is reduced by carbon in absence of oxygen (atmosphere of nitrogen) at temperatures between 850° C. and 1100° C. The amounts of carbon used in the reduction of zinc oxide in ordinary metallurgical practice are excessive.—P. **Nicolardot**, A. **Réglade**, and M. **Geloso**: The volumetric estimation of manganese. A study of the errors of Knorr's method.—F. **Gros**: Improvements relating to the commercial production of oxides of nitrogen in arc furnaces. The improvements described are the use of dried gases, increasing the amount of oxygen to 50 per cent., and the replacement of the alkaline absorption towers by a physical method, the separation of the nitrogen peroxide by cooling. The latter can be readily converted into nitric acid of any strength.—A. **Mailhe**: A new method of formation of nitriles by catalysis. Methyl benzoate and ethylamine, passed over alumina heated to 480°–500° C., gave benzonitrile. Paratoluic nitrile, *iso*amyl nitrile, and *iso*butyonitrile were prepared in a similar manner.—L. **Joleaud**: The presence of a Tomistoma in the fresh-water Pliocene of Ethiopia.—F. **Baldet**: The diurnal variation of the atmospheric potential at the Algiers Observatory. A discussion of five years' observations. The diurnal variation is represented by a simple oscillation having a constant minimum about 4 a.m. and a maximum variable with the season. The observations confirm the law of M. Chauveau.—P. **Girard** and V. **Morax**: Liquid exchanges by electrical osmosis through living tissues.—J. **Chaine**: The union of the paramastoid apophysis and of the temporal in mammals.—A. **Krempf**: The oro-aboral metamerisation of the larva of *Pocillopora cespitosa* and of *Seriatopora subulata*.

April 6.—M. Georges Lemoine in the chair.—G. **Rémoundos**: Increasing functions and entire functions.—P. **Humbert**: A new application of the function $W_{k,m,\nu}(x, y)$.—L. E. Z. **Brouwer**: Enumeration of the classes of transformations of the projective plane.—J. **Andrade**: Extension of conservative systems and a generalisation of a theorem of M. Painlevé.—Ch. **Fremont**: Cause of the undulatory wear of rails.—M. **Lecornu**: Observations on the preceding communication.—J. **Villey** and A. **Volmerange**: Hovering flight by a horizontal wind of invariable direction and velocity.—M. **Girousse**: The distribution in the soil of currents from electric traction lines.—P. **Job** and G. **Urbain**: The detection of masked sulphuric ions in complex compounds. The benzidine method of estimating sulphate ions is shown experimentally to possess advantages over the barium method. Examples are given of analyses of cobaltammine sulphates.—Ch. **Boulin** and L. J. **Simon**: The action of water on dichloroethyl sulphide. Using an excess of water at its boiling point, dichloroethyl sulphide can be completely decomposed, giving hydrochloric acid and thiodiglycol; the reaction is reversible.—P. **Fallot**: An extension of the phenomena of drift in the Sierra of Majorca.—G. **Dubois**: The Quaternary fauna of the base of the Ergeron at Cambrai.—L. **Besson**: The actinometers of Arago and Bellani. Details of the precautions necessary in the accurate use of these two instruments.—A. **Piutti**: The action of chloropicrin on the parasites of wheat and on rats. Large-scale experiments have proved the efficacy of chloropicrin in destroying wheat parasites, and it has also been demonstrated that the treated wheat is inoffensive and preserves its nutritive power. Chloropicrin has also been successfully employed in the destruction of rats in ships.—V. **Galippe**: Researches on the resistance of the microzymas to the action of time and their survival in amber.—G. **Bertrand**: The action of chloropicrin upon the higher plants. Under suitable conditions it is possible to use chloropicrin to free a plant from all its leaf parasites without killing the plant.

ROME.

Accademia dei Lincei, February 1.—A. Ròiti, vice-president, in the chair.—G. **Fubini**: Affine differential invariants of a surface.—Q. **Majorana**: Gravitation. This is the seventh note on the author's experimental attempts to detect the screening off of gravitation by massive sheets of matter (see NATURE for April 22, p. 251). The whole note is devoted to the search after, and the discussion of, "causes of error" or disturbing effects. These troublesome effects are now all estimated numerically, but, notwithstanding this, the author closes the present note, postponing the computation of the corrected value of the effect sought for to the next (viii.) note.—V. **Amato**: Kronecker's method for the decomposition of an integral rational function in an amplifield field of rationality.—P. **Scatizzi**: Abelian differential equations reducible to quadratures.—L. **Tonelli**: Primitive functions (ii.).—Clara **di Capua**: Investigations on alloys of Au and Si.—C. **Gorini**: A microbiological investigation of the behaviour of *Bacterium coli* in milk.

Diary of Societies.

THURSDAY, APRIL 29.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (at Royal Society of Medicine), at 10 a.m.—J. B. Story: Presidential Address.—C. H. Usher: Enlarged Corneæ in Goldfish.—E. Treacher Collins: Megalo-cornea and Micro-cornea.—J. Rowan: Are not some Cases of Glaucoma Better Treated without Operation, and, if so, what are the Indications?—A. Zorab: Later Notes on Aqueoplasty.—T. Harrison Butler: Notes on Infection after Operations for Cataract.—G. H. Pooley: Abnormalities of the Lacrymal Apparatus and their Treatment.—G. Harvey Goldsmith: A Case of Double-Traumatic Dislocation of the Lens.—G. F. Alexander: (1) A Position of the Head Favourable to the Operation for Cataract; (2) An Operation for Advancement in Strabismus.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—R. Campbell Thompson: The Origins of the Dwellers in Mesopotamia.

ROYAL SOCIETY, at 4.30.—Prof. J. W. Gregory: The Irish Eskers.—Miss K. M. Curtis: The Life-History and Cytology of *Synchytrium endobioticum* (Schilb.) Perc., the Cause of Wart Disease in Potato.—B. Sahni: The Structure and Affinities of *Acmopyle pancheri*, Pilger.

ZOOLOGICAL SOCIETY OF LONDON, at 4.30.—Annual General Meeting.

CHEMICAL SOCIETY, at 5.—Extraordinary General Meeting to consider the Alterations in the By-laws proposed by the Council.

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Sir A. E. Shipley: Biting Insects and Children.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—A. E. McColl: Automatic Protective Devices for Alternating Current Systems.

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—Dr. C. E. Kenneth Mees: The Reaction of the Eye to Light.

FRIDAY, APRIL 30.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (at Royal Society of Medicine), at 10 a.m.—Sir Archibald Garrod, R. Foster Moore, and Others: Discussion on Diabetes in Relation to Diseases of the Eye.—At 8.—H. M. Traquair: Anatomically Separate Anterior Commissure at the Chiasma in a Case of Pituitary Tumour with Acromegaly.—Dr. G. Holmes: Tumours Involving the Optic Nerves and Chiasma.—M. L. Hine: Primary Epithelioma of the Ciliary Body.—E. Clarke: A Further Note on the Accommodation of the Eye.—H. Neame: Cysts of the Retina.—W. Wallace: A Glyptic Method for Representing Certain Conditions of the Fundus in Disease.—A. W. Stirling: A Case of Melanoma of the Iris.

WIRELESS SOCIETY OF LONDON (at Institution of Civil Engineers), at 6.—Major B. Binyon: A Wireless "Call" Device.

INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at Faraday House), at 7.—J. E. Holmstrom: Tidal Power.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—A. P. Bale and Others: Discussion on Suggested Means of Improving and Increasing the Services of the Institution to Members.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. F. O. Bower: The Earliest-known Land Flora.

SATURDAY, MAY 1.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (at St. Margaret's Hospital, Leighton Road, Kentish Town), at 10 a.m.—Dr. G. Fitzgibbon, M. S. Mayou, and Others: Discussion on the Prevention and Treatment of Ophthalmia Neonatorum.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. F. Chamberlin: The Private Character of Queen Elizabeth.—At 5.—Annual Meeting.

MONDAY, MAY 3.

ROYAL INSTITUTION OF GREAT BRITAIN (General Meeting), at 5.

SURVEYORS' INSTITUTION (Junior Meeting) (Annual General Meeting), at 7.

ROYAL INSTITUTE OF BRITISH ARCHITECTS (Annual General Meeting), at 8.

ROYAL SOCIETY OF ARTS, at 8.—A. T. Bolton: The Decoration and Architecture of Robert Adam and Sir John Sloane, 1758-1837 (Cantor Lecture).

SOCIETY OF CHEMICAL INDUSTRY (at Chemical Society) (Annual Meeting), at 8.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—H. St. J. Philby: Across Arabia: from the Persian Gulf to the Red Sea.

TUESDAY, MAY 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology: The Invaders of England.

ROYAL SOCIETY OF MEDICINE (Orthopædics Sub-Section), at 5.—Annual General Meeting.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Technical Meeting), at 7.—Dr. C. E. Kenneth Mees and L. A. Jones: The Theory of Tone Reproduction.

RÖNTGEN SOCIETY (at Medical Society of London), at 8.15.—Prof. S. Russ: Some Problems in the Action of Radiation upon Tissues.—Prof. A. O. Rankine: The Transmission of Speech by Light.—Dr. H. A. Eccles: New Portable Viewing Lantern (Demonstrations).

WEDNESDAY, MAY 5.

ROYAL SOCIETY OF ARTS, at 4.30.—Dr. C. E. Kenneth Mees: A Photographic Research Laboratory.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—S. Hazzledine Warren: A Natural "Eolith" Factory beneath the Thanet Sand.

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 5.30.—Annual General Meeting.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—C. A. Mitchell: Estimation of the Age of Ink in Writing.—E. R. Dovey: The Estimation of Chinese Crude Camphor.—H. D. Richmond and L. R. Ellison: Studies in Steam Distillation, Part VII.: The Volatility of Isomers.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 8.—Major H. H. Thomas: The Electro-Deposition of Iron as applied to Motor Vehicle Repair Work.

THURSDAY, MAY 6.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers) (General Meeting), at 10 a.m.—Dr J. E. Stead: Inaugural Address.—E. H. Lewis: Iron Portland Cement.—At 2.30.—F. Clements: British Blast-Furnace Practice.—H. E. Wright: Chemical and Thermal Conditions in Blast-Furnace Practice.—C. H. Ridsdale: The Valuation of Ores and Iron-making Material.—J. A. Heskett: The Utilisation of Titaniferous Iron Ore in New Zealand.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section, conjointly with the North of England and Midland Obstetrical and Gynæcological Societies), at 10.30 a.m.—Dr. H. Tweedy and Others: Discussion on The Treatment of Antepartum Hæmorrhage.—At 2.—Dr. E. Holland and Others: Discussion on Rupture of Cæsarean Section Scar in Subsequent Pregnancy or Labour.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—R. Campbell Thompson: The Legends of the Babylonians.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: R. H. Fowler, F. C. Gallop, C. N. H. Lock, and H. W. Richmond: The Aerodynamics of a Spinning Shell.—Prof. W. E. Dalby: Researches on the Elastic Properties and the Plastic Extension of Metals.—C. T. R. Wilson: Investigations on Lightning Discharges and on the Electric Field of Thunderstorms.—L. F. Richardson: The Supply of Energy to Atmospheric Eddies.

LINNEAN SOCIETY OF LONDON, at 5.—Dr. G. P. Bidder: Notes on the Physiology of Sponges. *Pandorina spongiarum*, a New Species of Alga found in a Sponge.—E. J. Bedford: The British Marsh Orchids and their Varieties, Illustrated by Coloured Drawings and Lantern Slides.

CHEMICAL SOCIETY, at 8.—G. M. Bennett: The Mustard Gas Problem.—C. K. Ingold: A New Method of Preparing Muconic Acid.—J. W. Cook and O. L. Brady: The Dinitration of *m*-Acetotoluidide.—Y. Venkataramayya and M. V. Narasimhaswamy: A New Ozoniser.—G. T. Morgan and H. D. K. Drew: Orthochlorodinitrotoluenes.

FRIDAY, MAY 7.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers) (General Meeting), at 10 a.m.—C. A. Ablett: Direct Current compared with Three Phase Current for Driving Steel Works Plant.—J. F. Wilson: Notes on Slag Conditions in Open-hearth Basic Steelmaking Practice.—B. Yaneske and G. A. Wood: The Reduction of Silicon from the Slag in the Acid Open-hearth Process.—At 2.30.—W. E. Hughes: Some Defects in Electro-deposited Iron.—T. Baker and T. R. Russell: Note on the Ball Test.—J. H. Whiteley: The Distribution of Phosphorus in Steel between Points Ac_1 and Ac_3.—G. F. Preston: Practical Notes on the Design and Treatment of Steel Castings.

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 4.—Annual General Meeting.

ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Prof. R. A. Sampson and Others: The Use of Wireless Telegraphy in the Determination of Longitude.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Lord Rayleigh: The Blue Sky and the Optical Properties of Air.

SATURDAY, MAY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. F. Chamberlin: The Private Character of Queen Elizabeth.

BRITISH PSYCHOLOGICAL SOCIETY (at Bedford College), at 3.30.—Dr. E. W. Scripture: Speech Inscriptions in Normal and Abnormal Conditions.—A. Klein: Camouflage in Land Warfare.

The Cost of Scientific Publications.

WE have had before us recently the annual reports of the councils of a number of scientific societies, and it is evident from all of them that the burden of the cost of publications of these societies has become so heavy that it cannot be borne any longer without additional support. The great increase in printers' charges, and the high cost of paper, make the expenses of publication so considerable that the slender funds at the disposal of most scientific societies, particularly those devoted to subjects having no direct association with profitable industry, will often not permit the substantial expenditure now required for the printing and distribution of papers presented at meetings. Few scientific societies have any other source of income than that provided by the subscriptions of their members or fellows, and science workers in general are already sufficiently harassed by the problem of their private budgets, with salaries little above the pre-war level, and relatively far below it on account of the rise in prices, that increased subscriptions cannot be contemplated without serious misgiving.

It has always seemed to us that in the pursuit of their researches and the publication of the results science workers follow principles on a far higher ethical level than that occupied by members of any other profession. The first object of their work is to increase the store of human knowledge, and the value of any communication to a scientific society is measured by what the explorer has brought back from a known region, or how far he has lifted the veil with which Nature jealously guards her secrets. Nothing must be kept back from the narrative of the discoverer, and the fruits secured must be displayed so that all who wish may enjoy them and be able to go out into the same fields to secure like riches for themselves.

In presenting the results of his labour to the human race without receiving any personal payment for it, the science worker occupies a unique position. Genius in art, or literature, or music may sometimes be neglected, but usually it secures generous reward, and its products have always a marketable value—high or low—whereas scientific discovery rarely brings direct gain to the genius who makes it. Plutocrats will pay high prices for the pictures they want, and popular authors and musical composers may amass riches from royalties on their works; but the science worker is deprived of any such rewards for his discoveries, though all the world may benefit by them. Not only does he bring his rich argosies into port, but he also describes his cargoes fully, and himself pays for the publication of the catalogue of gifts which he is prepared to bestow freely upon all who care to receive them. Such pure altruism is almost inconceivable to the ordinary business mind, yet it represents the common standard of scientific endeavour and achievement. Altered circumstances, however, make it necessary to reconsider this position, and we urge that it is time the community, through its rich citizens or the Government, provided reasonable contributions towards the expenses of publications which bring honour to them as well as add to the sum of human knowledge.

There is, indeed, no more difficult problem before our learned societies at the present time than that of the maintenance of their scientific publications. With a limited circulation which cannot be increased by the ordinary methods of enterprising journalism, the additional cost of production can be met only by a higher subscription. The societies which provide a library of their special subject already find most of their normal income absorbed by the increased establishment charges. As we have said, a very large proportion of the members of these societies are professional men whose incomes have not risen in proportion to the prices of the ordinary commodities of life. Any additional subscription to provide for an adequate record of the societies' activities under present conditions thus proves to be a hardship, sometimes an impossibility.

It may perhaps be admitted that, in the past, scientific publications have sometimes been produced in a rather extravagant style. Some societies have never completely emancipated themselves from this idea, and although a large format may sometimes be needed both for drawings of natural history and engineering, and for extensive mathematical formulæ, there has been less strict regard to such necessities than should have been exercised. Moreover, during the years before the war, with cheap printing, there was an increasing tendency in some departments of science to pour forth the undigested contents of notebooks rather than carefully considered results.

After all reasonable reform and economy, however, it still remains impossible to continue the serial publications of science with the means that

have hitherto been at its disposal. The question arises, therefore, whether help from some public source may not reasonably be expected. There is doubtless a very general popular feeling that ordinary scientific research is as much a recreative amusement to its devotees as are games and sport to the majority, and that those who indulge their whims should bear the additional cost like any other section of the community. But it must not be forgotten that there are various degrees of games and sports suited to the several means of those who pursue them, whereas ability and inclination to make and record scientific discoveries are in no way proportional to the resources of those who possess them. It must also be emphatically maintained that there is no basis for such a comparison. Science is undoubtedly an absorbing source of gratification to those who study its problems; but even the most abstract research, however far removed from the affairs of everyday life, is an asset of which no man can estimate the value.

In some directions the public has already become accustomed to the scientific spirit. It has begun, for example, to understand the value of preventive medicine. It no longer reserves its gratitude for those who discover remedies for disease; it realises the still greater importance of the work of those who try to learn the origin of disease and the influence of the environment upon the exciting cause. It should now be led to understand its debt to those who make advances in this and other branches of purely scientific work. The germs of all material progress and comfort are contained in our scientific serials and the publications of our scientific societies, and to allow a limitation of their scope is a hindrance to the public welfare.

The Government has already aided a few of the older and more important societies with a partial or complete grant of premises, and it entrusts an annual sum of money, given in the Estimates of 1920–21 as 11,000*l.*, to the Royal Society, to be distributed for scientific investigations by a committee appointed for that purpose, as well as 1000*l.* annually towards the cost of scientific publications. It has also established the important Department of Scientific and Industrial Research. We would now urge that a further step should be taken, and some direct endowment provided for those purely scientific publications which have for so many years been maintained by voluntary effort, both to the honour of the country and to the welfare of mankind.

Physiology and National N—

W. D. Halliburton. Pp. vii+[illegible] don: Constable and Co., Ltd., 1919.) Price 8*s.* 6*d.* net.

PROF. HALLIBURTON and his fellow-lecturers have made out a good case for physiology having done its bit in the great war. The editor leads off with an account of the activities of the Royal Society and other committees in food control in general, and gives more particular details of the inquiries made in his own laboratory on the value of margarines and fatty acids. Vitamines occupy the whole of Prof. Hopkins's discourse, and Prof. Harden returns to them again with a summary of the work done on scurvy at the Lister Institute. But Prof. Harden is surely in error in saying that Lind held that scurvy was caused by abstinence from fresh vegetable food. That astute observer knew 150 years ago that scurvy could be cured by fresh vegetables, but he thought it was caused by living in confined, damp quarters, arguing that no one would say that ague was caused by abstinence from bark because it could be cured by giving bark.

Prof. Paton's essay on physiology in the study of disease is much less satisfactory. He is under a complete misapprehension of the aim and objects of medicine—a mistake shared in part by Prof. Halliburton—and medical men who read his solemn castigation of their empirical methods may not unreasonably retort that his discovery that tetany is due to the liberation of guanidin, controlled "somehow" by the parathyroids, has left medicine just about where it was. Prof. Paton seems to think that the object and business of medicine is to study disease. The object of medicine in reality is to prevent people feeling ill, and to make those who do feel ill feel better, and its success is to be measured by the product of the degree of betterment and its duration. "What the physician has to find out in every case," he says, "is simply what has gone wrong, and why it has gone wrong, before he attempts to put it right." So that if I have a headache and send for my physician, he is to engage with the hitherto insoluble problem of the nature and cause of the common megrinous headache (which is one of the great causes of human inefficiency, and no trivial matter) and solve it before he cures me by exhibiting 10 grains of aspirin: it might be good physiology, but it would be thoroughly bad medicine. The "practical man" is of course very wicked from our point of view, but he has been belaboured pretty freely these last few years; and, after all, he does a lot of practical good in

his blundering way. Genius, as Mr. Belloc says, would sink if he stopped to meditate about the surface [illegible] he might get no nearer the truth than Prof. Paton does when he affirms that phosgene yields chlorine in the lungs. Knowledge helps practice truly enough, but to ask that practice shall stand still while a particular sort of intolerant knowledge gropes to a rationale will meet no national need whatever.

Prof. Dendy's interesting account of the ravages of weevils in stored grain and the means of preventing them tells, on the other hand, an excellent tale of practical empiricism. Prof. Dendy found, as on general grounds he expected to find, that the weevils soon perished if infested grain was shut up in air-tight receptacles in which the metabolism of the seeds soon replaced most of the oxygen by carbon dioxide, and he shows with a variety of experiments that air-tight storage is the practical method which is wanted: which appears to have been known from time immemorial and is expressed in the habit of Indians, Maltese, and others in storing their harvested grain closely in covered, underground pits in face of the opinion that it was "absurd to hold that weevils require a free play of air or that free access of air is favourable to their existence," given by the entomological expert—doubtless a mere morphologist.

Natural man, indeed, as Dr. Pembrey argues in his breezy plea for the wild life, is apt to go right: "A sturdy growth of children is not to be obtained by the intelligent selection of the quality or quantity of their diet, but by the natural process of muscular activity in the open air, the appetite with its likes and dislikes acting as the guide in questions of food" (p. 158), which is not quite what the editor seems to say (p. 23). But the discrepancy is only on the surface: Sussex is not the Marylebone Road, and it is when civilisation interferes that trouble comes. Western refinements in rice polishing gave the East beriberi; a world trade in wheat gave the weevils their chance; mean and restricted lives brought in physical exercises instead of games. The truly physiological procedure, says Dr. Pembrey, is to put people where they can live a natural life by accumulated experience and to let them live it. "Bread and cheese" off the hedges is an older remedy than orange juice, and even scientific opinion has been taught by Prof. Leonard Hill that there is something to be said for our primitive open fires.

The book as a whole is extraordinarily interesting from many different aspects, as much perhaps for the questions it asks as for those it answers. "Physiology" is conceived in no narrow spirit; it is hygiene, pathology, bacteriology, and pharmacology, as well as itself. And in this generous field everyone will find a good many things worth thinking about.

A. E. B.

Service Chemistry.

Service Chemistry: Being a Short Manual of Chemistry and Metallurgy and their Application in the Naval and Military Services. By the late Prof. Vivian B. Lewes and Prof. J. S. S. Brame. Fifth edition. Pp. xvi+576+vii plates (London: Edward Arnold, 1920.) Price 21s. net.

THE late Prof Vivian Lewes, of the Royal Naval College, Greenwich, an excellent teacher and an admirable lecturer, conferred a great benefit on the Service of which he was a member by the compilation of this manual. In the early days of the history of the college, the relation and importance of physical science to the business of the naval officer were but dimly appreciated by the authorities at Whitehall, and the scheme of instruction at Greenwich went but little beyond the standard of a public school which sought to develop its modern side. Prof. Debus, the first professor of chemistry, although a sound and remarkably well-informed chemist, carried with him to the college merely the traditions and methods of Clifton. The scope of his instruction of the naval lieutenant was practically that which had served him for years past in the several public schools to which he had been attached. He continued to teach chemistry simply as a branch of a liberal education, with no very direct reference to the life-work of those whom he addressed. It may be that at the outset of the career of the college no other course was open to him. The preliminary education of a naval officer at that period afforded no opportunity for him to acquire even the most elementary knowledge of science, and hence his teacher had of necessity to restrict himself to the kind of instruction which a well-ordered school system ought to have supplied.

Prof. Debus exercised a very salutary influence at the Royal Naval College. He was personally popular, and, in spite of certain little mannerisms, his quiet dignity and personal bearing enabled him to keep an effective control over a class of young men whose sense of humour is proverbially always acute and occasionally irrepressible. But to the budding Nelson, keen on his job, there must have been much in the professor's teaching that made no appeal. It probably seemed to him to have no possible relevance to the work of his pro-

fession. Prof. Lewes, who acted as chief assistant to Prof. Debus for some years and eventually succeeded to his chair, was no doubt fully conscious of this fact. At all events, his intimate association with the young officers in the laboratory must have afforded him abundant opportunities of learning it. When his turn came he entirely remodelled the course of chemical teaching. During the years of his assistantship he had been brought into frequent contact with Service and dockyard problems, in which his chemical knowledge and practical aptitudes could be turned to account. Prof. Debus was essentially the philosophic student; Prof. Lewes, with no pretensions to the academic attainments of his predecessor, was more a man of affairs, with a keen appreciation of the value of science to practice, and he could bring his experience to bear upon the character and style of his teaching.

The book before us was written to aid and supplement Prof. Lewes's instruction. It was unique of its kind. It bore directly upon what he conceived to be the true function of his chair. In one sense it is more restricted in scope than the ordinary text-book of pure chemistry, which seeks to cover more or less fully every department of the science, with no special reference to its practical application; in another sense it is wider, inasmuch as its subject-matter is intended to lead up to the far-reaching problems with which modern Service conditions deal.

A book based upon such principles can continue to be of value only so long as it has regard to the constant changes and increasing complexity of these conditions. Each successive edition bears witness that such regard has been held. The four previous editions of the work were issued under the direction of the original author, the fourth having appeared in the year before the outbreak of the war.

The present edition—the fifth—is due to Prof. Brame, Prof. Lewes's successor at the Royal Naval College. The plan of the work has not been altered in any essential particular. But the text has been carefully revised, and certain new features have been introduced. Greater attention has been paid to the applications of organic chemistry, especially in relation to fuels, explosives, and oils, mineral and vegetable. Also, the sections on boiler waters, corrosion, pigments, etc., have undergone considerable alteration.

It has become a truism to say that the great war through which Europe has recently passed was a chemist's war. Whether that is wholly true is a matter of opinion. But it is at least universally acknowledged that chemistry entered more largely into it than into any previous war. That fact alone adds interest and value to a book of this kind. Both arms of the Service now recognise that the operations of modern warfare are largely dependent upon chemical principles. That dependence is bound to increase in the future, and should therefore lead to a wider recognition of the importance of chemical instruction to all who may be concerned in the conduct of war, whether afloat or ashore. The book before us makes mention of many chemical applications and adaptations which the war originated; but the complete story has yet to be told, and in the present unsettled state of the world some time must elapse before it can be published. When, however, it is made generally known, it will constitute a triumph for the knowledge, skill, and resourcefulness of British chemists. That fact is already appreciated in the Naval Service, and by no section more warmly than by those who owe their chemical knowledge to the instruction they have received at the Royal Naval College.

T. E. THORPE.

Euclid's Elements.

Euclid in Greek. Book I. With Introduction and Notes. By Sir Thomas L. Heath. Pp. ix+239. (Cambridge: At the University Press, 1920.) Price 10s. net.

THE editor of this text expresses the hope that it may be read by boys in the higher forms of schools. We hope so too, although the price of the book is rather prohibitive. At any rate, a copy should be obtained for the school library.

The text is accompanied by an introduction and a set of explanatory and critical notes; each of these is a model of its kind. In the introduction we have a summary of the contents of the elements, all the facts known about Euclid's life and works, and a full account of the principal translations and editions of the elements. The notes are extremely valuable in various ways. In the first place, the author is both a competent Greek scholar, and also a student imbued with the unadulterated spirit of Greek geometry. This makes his translations of technical terms eminently apt and trustworthy. As an example of his critical ability, we may take his discussion of the very difficult phrase ἐξ ἴσου in Euclid's definition of a straight line. He shows, we think conclusively, that the intention of the definition is to express that if any point on the (indefinite) line be taken, what we may call the aspect of the line therefrom is an "indifferent" one, with no bending one way or the other; in fact, we have an attempt at expressing in abstract terms the Platonic test—that a straight viewed "end

διχα is a point. The editor keeps the time-honoured rendering "evenly"—we should prefer "equably" or "indifferently"; but this is of little importance, because, whatever term is used, it will have to be carefully explained. In any case, Simson's definition is a gross misrepresentation of Euclid, who evidently, however obscurely, states a property of a straight line in relation to all the points upon it.

Owing to the great popularity of the Elements, it is unlikely that we shall ever find out exactly the contributions made to geometry by Euclid's predecessors. Naturally, we should like to know what were the attainments of the Pythagorean school, and how far they were arithmetical or geometrical respectively. A still greater satisfaction would be to know how far the Greek theory of proportion was developed by Eudoxus. As presented in the Elements, it may fairly be called the crowning triumph of Greek mathematics; it is so near absolute perfection that no recent analysis can amend it, except perhaps by explicitly introducing what is known as the axiom of Archimedes. The question is, How far, if in any way, did Euclid improve upon Eudoxus's exposition?

We do not know whether Sir T. Heath intends to publish all the other books of the Elements. Those who are interested in Greek mathematical thought would be grateful for a similar edition of Euclid's arithmetical books, especially the tenth, which, as De Morgan pointed out long ago (in Smith's Dictionary of Classical Biography), contains an exhaustive discussion of a particular family of irrationals. Another boon would be an edition like this of some of the books of Apollonius's "Conics," especially those which virtually give the equations of conics referred to a principal diameter and the tangent at a vertex.

There is one point on which we venture, with all deference, to disagree with the editor. On p. 175 and elsewhere he translates πολλῷ μείζων by "much greater." The Greek idiom is peculiar, but unless we are to make it absurd we must render πολλῷ by "all the more," or some such phrase.

One remark in conclusion. Forty or fifty years ago, when a blind idolatry of Simson's "Euclid" was still the vogue, Euclid's fifth book was never read, and its theorems were assumed on the basis of Todhunter's "Algebra." In other words, the greatest achievement of Greek mathematics was absolutely ignored. It is a great mistake to assume that all who are in favour of modern methods of teaching are wholly out of sympathy with the classic exponents of their subject. On the contrary, those of them who are sane psychologists will always bear in mind that the progress of the individual is, in a way, a condensed image of the progress of the race, and they will be the last to ignore the historical development of their subject, whether it be mathematics, or philosophy, or chemistry, or anything else. G. B. M.

The Earliest Flint Implements.

Pre-Palaeolithic Man. By J. Reid Moir. Pp. 67+29 plates. (Ipswich: W. E. Harrison; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., n.d.) Price 7*s.* 6*d.*

IN this little volume Mr. Reid Moir treats of the various forms of flaked flints found in deposits older than those in which ordinary palæolithic implements occur. He also describes the experiments in flint-fracture which have convinced him that the specimens in question are examples of human workmanship. Most of the matter has already appeared in various papers by the author, and many of the illustrations are from these papers, but the whole is a useful summary which the general reader will be glad to have in so convenient a form.

Among flints like the so-called eoliths, which are very little shaped by chipping, it must naturally be difficult to decide which have been flaked by man for his own use, but Mr. Reid Moir considers that they can be distinguished by the shape and appearance of the flake-scars. According to his experiments, the scar left by fortuitous percussion is comparatively wide and truncated, and often marked by concentric lines, while that made by human flaking is longer than it is wide, tapering at the far end, and not marked by concentric lines. If this criterion be trustworthy, it is evident that man's earliest handiwork can be recognised, for when he first began to use stone he must have selected pieces which were already of the needed shape, and he merely trimmed certain edges for greater effectiveness.

Man's first efforts to shape a real implement are supposed to have resulted in the rostro-carinate type, and this by further chipping gradually passed into the familiar palæolith. Mr. Reid Moir describes the process of change, as further discussed in his memoir in the Philosophical Transactions which was noticed in NATURE for April 1, p. 146. He also, as in the memoir just mentioned, expresses the opinion that the Acheulean and the Mousterian forms of palæoliths have been derived from the rostro-carinates in somewhat different ways. The speculation is interest-

ing, and the argument is easily followed with the aid of the many accompanying illustrations.

Mr. Reid Moir's final chapter on "Pre-Palæolithic Man in England" is more discursive, and suggests that we should turn to England rather than to Asia for the earliest traces of man. The detritus-bed at the base of the Pliocene Red Crag near Ipswich is described as yielding rostro-carinate and other worked flints. The age of the Piltdown skull is also discussed, and it is regarded as Pliocene. The conclusion is that English "pre-palæolithic" deposits should be more carefully studied than they have been hitherto, and the little book before us cannot fail to stimulate such study.

The Heat Treatment of Cast Iron.

Malleable Cast Iron. By S. Jones Parsons. Second edition, revised. Pp. xi+175. (London: Constable and Co., Ltd., 1919.) Price 14*s.* net.

THE first edition of Mr. Parsons's book on malleable-iron founding was published in 1908. A second edition has now been issued. It differs principally from the first in that it contains two new chapters, one dealing with mixing by analysis, the other with the measurement of temperature. There is also a brief addendum on what is called "malleable cast steel."

The high percentage of "waster" castings formerly produced in malleable-iron foundries has undoubtedly been reduced in the interval which has elapsed between the appearance of the two editions by adopting a more scientific method of making up mixtures according to chemical standards; but this alone is not sufficient to ensure a continuous output of good malleable castings. There has always been an undue amount of wastage in the annealing process, chiefly owing to irregularities in the temperature of the ovens. This is inevitable when there is no means provided for measuring the temperature. In the best foundries the hopelessness of relying on the purely human element has long been recognised, and it has now been proved by the use of suitable pyrometers that a considerable saving in fuel may be effected and the percentage of waster castings due to imperfect annealing almost entirely eliminated. The chapter on temperature measurement gives a brief account of optical and thermo-couple pyrometers and the methods of using them in this industry.

It is somewhat surprising that in a book which is evidently designed to assist the malleable-iron industry to more scientific methods of production there is no mention of the light thrown by the microscope on the structural changes which occur in the malleablising process; nor is there any reference to the mechanical properties of the various types of iron produced. It is the microscope which has shown what the essential difference is between European malleable iron, which dates back to the time of Réaumur, and the modern "Black Heart" variety, which is an American product. This instrument affords a valuable means of controlling the extent of the malleablising action of the annealing process.

A valuable account of these two aspects of the scientific control of malleable iron is to be found in Dr. Hatfield's book "Cast Iron in the Light of Recent Research." If a third edition of Mr. Parsons's book is called for he would be well advised to include a reference to these additional methods of control.

Our Bookshelf.

The Running and Maintenance of the Marine Diesel Engine. By John Lamb. Pp. xii+231+4 plates. (London: Charles Griffin and Co., Ltd., 1920.) Price 8*s.* 6*d.*

THIS book opens with brief descriptions of the properties of oil fuels, combustion, the modes of working of four-cycle and two-cycle engines, and the general arrangement of the marine Diesel engine on board ship. The remainder of the book is taken up with descriptions of details and the manner in which these operate; sections are included dealing with high-speed Diesel engines for driving dynamos and fans, steering-gears, running troubles, and lists of stores which should be carried. The book is profusely illustrated with diagrams showing the construction of details; as the author's object has been merely to explain the mode of working, many of these diagrams have not been drawn to scale; detailed descriptions of parts which are common to all classes of engines, *e.g.* connecting-rods and crank-shafts, are not included.

The book will appeal to and be found useful by a large class of engineers whose experience has been confined to the steam engine, both by reason of the clearness of the matter included and by the many useful hints which the author's four years' sea-going experience in motor ships has enabled him to give. For example: "In the same vessel the scavenging valves would intermittently fail to close, frequently to such an extent that the escape valves on the scavenging air pipe would lift. The scavenging pumps drew the air through a ventilator passing up through the deck. It was afterwards found that scale from the inside of the ventilator was the cause of the valves failing to close. The air was then taken from the engine-room, when no further trouble was experienced." Obviously hints of this kind are of service not only to the engineers on board ship, but also to the

designer. We can recommend the book to all engineers desirous of obtaining information on the running of Diesel engines.

A Course of Practical Chemistry for Agricultural Students. Vol. i. By L. F. Newman and Prof. H. A. D. Neville. Pp. 235. (Cambridge: At the University Press, 1920.) Price 10s. 6d. net.

MR. NEWMAN AND PROF. NEVILLE have brought into three volumes details of a practical course of agricultural chemistry designed for students taking degrees in agricultural science; the present volume deals with the chemistry and physics of the soil. Much of the book is concerned with pure chemistry and pure physics (physical properties of gases, density, specific heat, etc.), and has no special connection with agriculture as distinct from any other branch of science; only about one-third is devoted to soils and manures.

The exercises appear to be well chosen, but one cannot help wishing that the authors had used one of the many books already published on pure chemistry, and given more space to agricultural problems.

The exercises on soils and manures are mainly analytical; they are on the usual lines, and intended obviously for elementary students, for whom the instructions should be found sufficient Had there been more space available, some more inspiring exercises might well have been given, especially in the direction of pot and plot experiments. Many of the properties of soil are more easily demonstrated out of doors than indoors, and in any case the principles of soil fertility cannot be elucidated entirely by purely laboratory work. Numerous experiments have been devised, but they are scattered about over a number of text-books and have never been collected.

Within the limits they have set themselves, the authors have produced a useful book which will be helpful to teachers, especially in these busy times, when classes are large and demonstrators very hard-worked.

The Mason-Wasps. By J. Henri Fabre. Translated by Alexander Teixeira de Mattos. Pp. vi+318. (London: Hodder and Stoughton, n.d.) Price 7s. 6d. net.

THE writings of few open-air naturalists have equalled, or even approached, in ease and attractiveness of style the "Souvenirs entomologiques" of J. H. Fabre, the veteran observer of Sérignan. Much of the charm of these essays has been preserved in the skilful translations by A. T. de Mattos, of which the present work is an example in no way inferior, either in interest or in wealth of accurate observation, to the other volumes of the series. In it are recorded the results of a minute and careful study of the life-history of wasps belonging to the genera Eumenes, Odynerus, Pelopœus, Agenia, and Vespa, related with the utmost simplicity and vividness, and illuminated by the lively and charming personality of the author.

Leaving the domain of pure observation and experiment, and entering on that of bionomic speculation, we find Fabre a less satisfactory guide. It is well known that no theories of evolution appealed to him in the least degree, and the *naïveté* with which he touches and dismisses the problems of mimicry and protective resemblance in the volume before us gives a key to the reasons of his failure to appreciate the greatest advances in biological science of his time. On the other hand, his views on the subject of instinct, fortified by ingenious experiments on the mud-building and spider-storing habit of Pelopœus and on the cocoon-weaving procedure of Saturnia, are sound enough But it is difficult to follow him in the distinction that he draws between "instinct" and "discernment"; nor can one take seriously his playful remarks on the mental processes involved in insect activities. F. A. D.

The Handbook of Cyprus. Eighth issue. Edited by Harry Charles Luke and Douglas James Jardine. Pp. xii+300. (London: Macmillan and Co., Ltd., 1920.) Price 12s. net.

To every Englishman—and by that we mean every English-speaking citizen of our Commonwealth—Cyprus suggests, not the succession of love-cults, but that one great lovers' meeting when Othello came to land. "Once more well met in Cyprus." This new issue of the official handbook assures us that the island is now a Crown colony of Britain. Let us trust that its authors, who are both administrators of empire, in reviewing their work among its mixed inhabitants, may record that they "have found great love amongst them."

It is rare to find a publication that in its essence is economic and statistical allowing also for the taste of visitors in archæology and natural history. Enough is here given in a small compass to lead the reader on to the works enumerated on pp. 93-95 and in the sections on geology and zoology. It would have been well if the treatment of the geology had been connected with the brief geographical section which occurs some two hundred pages earlier. The comparatively recent origin of the islands of the Levant, consequent on the breaking up of the Ægean land, is the real basis for the history of merchant fleets. The dwarf elephant and hippopotamus, so well included under Natural History on p. 246, are effective links in the romance. We find so much in this invitation to the isle that we should like to arrange it more in sequence, so as to produce the true geographical effect. Perhaps each reader will do this for himself as he journeys eastward, sure of welcome. G. A. J. C.

An Introduction to Social Psychology. By Dr. W. McDougall. Fourteenth edition. Pp. xxiv+459. (London: Methuen and Co., Ltd., 1919.) Price 7s. 6d. net.

IN this edition, among other changes, the principle is elaborated that all emotion is the affective aspect of instinctive process.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Organisation of Scientific Work.

I HAVE only recently seen the article in NATURE of February 19 and the correspondence so unanimously supporting the view that the present decentralised system of team work by experts in different branches of science in agricultural, forestry, and medical research institutes is greatly superior to the proposed centralisation in distant Simla of each separate science —chemistry, botany, etc.—under directors of research with autocratic powers to decide what each original worker in his branch throughout India shall investigate and publish; for it is clearly impossible in these days for one man to be sufficiently conversant with each special division of his science adequately to fulfil such a stupendous task. I desire to associate myself with that view, which may be illustrated by my experience in organising the Calcutta School of Tropical Medicine, shortly to be opened, for which I have just obtained endowments from two successful European and Parsi business men for a whole-time biochemist, in addition to two other chemists for the analysis of indigenous drugs and of food and water respectively, all three of whom will aid nine medical research investigators in team work at important medical problems under a medical director. Could anyone contend that these very specialised chemists would be better controlled by a purely chemical director a thousand miles away in Simla, who could know nothing of the medical problems they will investigate?

On the other hand, if the Government of India is to provide the large sums urgently required for the further development of scientific research in India, it will require some organisation to co-ordinate and report on the work it will be financing. May it not learn a lesson from the Medical Research Committee of eminent medical men of science, which is wisely utilising the large sums supplied by the British Government in assisting the investigations of university and medical-school workers with established reputations and with a minimum amount of interference? A very similar and successful organisation was set up in India when the late Sir Pardey Lukis persuaded the Government of India to hand over five lakhs (some 50,000*l.*) a year to the Indian Research Association, administered by a governing body on which the medical members, through their special knowledge of the subject, exercise a preponderating influence; while I have recently obtained a purely medical governing body to administer the endowments of the Calcutta School of Tropical Medicine with an income of some 11,000*l.* a year, which I have been fortunate enough to raise to provide both men and apparatus without the long delays, usually of several years' duration, involved in obtaining the sanction of the Government of India and of the Secretary of State for new posts.

This plan has thus already proved its value and is capable of extension, while boards composed of a number of men of science of high standing will command much greater confidence than an autocratic director of research. The nucleus of such a body already exists in the Board of Scientific Control, which meets twice a year in Delhi and Simla, and might with greater advantage hold its principal meeting coincidently with the Indian Science Congress in one of the large centres of research. At a meeting in Delhi in December, 1918, I advocated, in place of an autocratic director of medical research, that an inspector of research might be appointed, who would not attempt the invidious task of laying down what each research worker should investigate and publish, but would visit different research laboratories and consult with their respective directors or councils regarding the financial and other needs of the institutes, and help to co-ordinate the work in different parts of India to prevent waste through overlapping. The recent correspondence in NATURE confirms me in that solution of the difficulty, and I venture to think that in some such ways as I have suggested the established advantages of the present decentralised system may be retained and strengthened by greater and more elastic financial aid, and be better coordinated, without introducing the highly objectionable autocratic and distant centralised control of the proposals now before the Indian Government to which you have directed such timely attention.

LEONARD ROGERS.

South Devon, April 29.

The Small Islands of Almost-Atolls.

THE familiar inductive series of fringing reefs, barrier reefs, and atolls may be further subdivided so as to contain six members: Normal fringing reefs, offshore fringing reefs, narrow-lagoon barrier reefs, broad-lagoon barrier reefs, almost-atolls, and atolls. Almost-atolls, or atoll-like reefs encircling lagoons in which one or several small islands rise, are of interest as affording a critical test of certain competing coral-reef theories, as follows: Murray's theory of outgrowing reefs around still standing islands explains a completed atoll by supposing that the original volcanic island is slowly worn down as the encircling reef grows outward and the lagoon is excavated behind the growing reef by solution, the degraded central island eventually disappearing in a way not clearly explained, perhaps by outwash of its detritus from the lagoon by currents which are fed by the influx of surf over the windward reef and discharged by outflow through passes in the leeward reef. Under this theory the small island of an almost-atoll would be a nearly worn-down central island, which would exhibit rolling hills of low relief surrounded by delta flats; or in a later stage, after the delta deposits had been swept away, the low hills of the vanishing island would be encroached upon by the lagoon waves and cut back in low bluffs fronted by low-tide rock platforms that gradually deepen into the lagoon.

According to Daly's Glacial-control theory, atoll reefs are built up from the margin of platforms abraded by the waves of the lowered Glacial ocean across still standing islands that had been previously worn down to low relief by long-continued normal erosion, the reefs being built up as the ocean rises in post-Glacial time. Under this theory an almost destroyed central island would have a surface of rolling hills, cut back by cliffs which would now—except for fringing reefs that may border them—plunge into the lagoon waters to a depth of twenty or more fathoms. This inference is well supported by the occurrence of strongly clift islands surmounting submarine banks of moderate depth in the extra-tropical seas. According to Darwin's theory of upgrowing reefs on intermittently subsiding foundations —submergence by subsidence being faster than erosional degradation—atolls are produced when the central island of an up-growing barrier reef has sunk out of sight. Under this theory the lagoon of an

almost-atoll would contain one or several nearly submerged islands of mountainous or mountain-top form.

The characteristics of the small islands of hypothetical almost-atolls, as thus deduced from several theories of coral reefs, may be confronted with the appropriate facts as represented in five actual almost-atolls: The Hermit Islands, in the Admiralty group north of New Guinea; Truk or Hogoleu, in the Caroline Islands; Budd Reef, in north-eastern Fiji; the Great Astrolabe Reef, in south-western Fiji; and Mangareva or the Gambier Islands, south of the Paumotus. The Hermit Islands are enclosed by a reef about 12 miles in diameter; the largest of the islands is 3 miles long and more than 3000 ft. in height. The encircling reef of Truk is about 30 miles in diameter, and encloses some twenty small islands; the largest measures 6 by 3 miles, and several of the larger ones are from 1000 ft. to 1300 ft. high; the smaller ones rise from 20 ft. to 300 ft. Budd Reef measures 12 miles in its longest diameter; three small islands, each less than a mile across, rise from 280 ft to 480 ft. near the lagoon centre; a small horseshoe crater island, a mile in diameter and 590 ft. high, near the north-eastern angle of the enclosing reef, appears to be of much more recent origin than its neighbours, and does not bear on the problem here considered. The Great Astrolabe Reef makes an oval loop, 6 miles wide by 10 miles long, around a lagoon containing nine small islands; it is not properly an almost-atoll reef, for on the south it continues a long distance around the four-mile island of Ono and the thirty-mile island of Kandavu. However, the small islands that its northern loop surrounds are typical residuals; the largest is scarcely a mile in length, the highest rises 460 ft.; all are of rounded, mountain-top form, their small spurs being a little cut back by shore-line cliffs, which rise from low-tide rock platforms and do not plunge into deep water. Moreover, a triangular space defined by three of the islands, a mile and a half on its open sides, has the same depth of from 17 to 20 fathoms that prevails between the islands and the barrier reef; and this is beyond explanation by the Glacial-control theory. Gambier Reef is from 12 to 15 miles across; the enclosed islands are eight in number, and the largest of them measures 4 by 2 miles and has a height of 1300 ft Dana wrote of the larger of these islands: "The very features of the coast—the deep indentations—are sufficient evidence of subsidence to one who has studied the character of the Pacific islands; for these indentations correspond to valleys or gorges formed by denudation during a long period while the island stood above the sea" ("On Coral Reefs and Islands," 1853, p. 95). Within the polygon defined by several of these islands two soundings give depths of 38 fathoms, while the lagoon outside the polygon has no depths so great.

All these almost-atoll islands are of mountainous or mountain-top form; they appear to be residuals of originally larger islands, much reduced by sub-aerial erosion and now isolated by submergence The smaller ones are mere summits, too small to show embayed valleys; the larger ones have somewhat embayed shore-lines, which would, according to the best accounts that I can gather, be more strongly embayed if the deltas that now partly occupy the bays were removed None of the islands are described as strongly clift, like those of the extra-tropical seas, although some headlands are a little cut back in low bluffs fronted by low-tide rock platforms, evidently the work of the lagoon waves at present sea-level. It thus appears that the small islands of actual almost-atolls are excellent counterparts of the mountainous or mountain-top islands of hypothetical almost-atolls deduced as the necessary consequences of Darwin's theory, but such islands cannot be accounted for by either Murray's or Daly's theory.

The attention of European men of science has been so largely withdrawn from the study of coral reefs during the last thirty years that the coral-reef problem now has scarcely a hearing among them. It is to be hoped that, with the acquisition of the numerous islands and reefs of northern and eastern New Guinea with the neighbouring reef-encircled islands by Australia, the old problem may be taken up again by the explorers and investigators of that remarkable region. The Louisiade group in particular deserves attention. The present communication suggests some of the newer aspects of coral-reef study, which, along with the embayments of reef-encircled islands and the unconformable contacts of fringing and elevated reefs with their foundations (see "The Geological Aspects of the Coral-reef Problem," *Science Progress*, xiii., 1919, pp 420–44), must be taken into account for the future. All considered together, these newer aspects go far towards restoring confidence in Darwin's theory, which between 1880 and 1910 was so unreasonably discarded by many writers The theory needs subordinate modification by the addition of changes of ocean level during the Glacial period, to which Daly has so justly directed attention; but those changes acting alone would, whenever they occurred, produce emergences or submergences everywhere alike in their moderate amount, their slow rate, and their Pleistocene date, while all the reef-encircled islands that have yet been studied—as, for example, in Foye's "Geological Observations in Fiji" (Proc. Amer Acad of Arts and Sci, liv, 1918, pp. 1–145)—testify to submergences and emergences at dates that are frequently unlike from place to place, and of amounts that are frequently much in excess of the most liberal estimates of Glacial changes in ocean-level Such submergences and emergences are, therefore, to be explained by local movements of subsidence or upheaval in the islands concerned. As reef-growth has been associated chiefly with the various movements of subsidence, reinforced recently by rise of ocean-level, Darwin's theory subordinately modified is thereby supported. W. M. DAVIS.

Scientific Apparatus from Abroad.

THERE is one aspect of the proposed "anti-dumping" legislation to which I should like to direct attention.

While there is much scientific apparatus made in the British Isles of a quality at least as good as that imported, it is, unfortunately, very costly. But there are also many articles which our manufacturers have not yet learned to produce in anything like a satisfactory quality The result of restricting the import of good articles by a heavy duty would be to compel scientific workers to use home-made goods. There would be no hardship if these goods were satisfactory. But such is by no means always the case, and we are then penalised by waste of time and frequent loss of experimental results. Moreover, if inferior goods obtain a sale by methods of this kind, no inducement is given to the makers to improve the quality.

I am aware that I may be called a doctrinaire Free Trader, but it seems to me to be a far more reasonable procedure to allow free import of such apparatus *until* equally good material is to be had cheaply at home. In the meantime, our manufacturers should,

if necessary, receive State aid to enable them to perfect their processes. When they can show that they have attained success, an import duty might be imposed temporarily on the foreign substitute to ensure the sale of the British article and to introduce it to the market. If the product is satisfactory, there would be no need to retain the duty for any great length of time.

Owing to the present poor rate of pay of free scientific workers, it is only just to give them generous grants if they are compelled to buy the costly home-made goods of the first category referred to above.

It will surely be admitted that the desirable state of affairs is that each country should produce what it is best fitted to do, and that there should be no necessity for protective duties. But if the League of Nations is believed to be ineffective, and if we must be prepared to be self-supporting in case of another great war, it behoves those who advocate measures to bring this about to see that the nation does not lose more than it is likely to gain.

I have confined my remarks to the case of scientific appliances, but similar considerations apply to many industrial processes. Inferior material and machinery would have to be put up with for the sake of supporting some other industry. If the foreign goods are superior they should be freely imported, and the British makers subventioned until they can produce equally good material, if it is thought essential that they should do so.

University College, London.

The Cost of Laboratory Fittings.

IN all directions we have at the present time evidence of a growing enthusiasm for education in the field of natural science. Students are being turned away from our schools and universities for lack of accommodation, and the new Education Act has given great encouragement to science teaching. Our war experiences seem to have aroused the nation to the necessity for vastly extending the facilities for these studies, and at the same time the need for financial economy is pressing in all directions.

The material requirements of science teaching are expensive, and, though heavy outlay is in the main inevitable, it seems probable that if costs cannot be reduced the very necessary expansion of science in our schools may in many cases have to be deferred or abandoned, and, possibly, curtailed in our higher institutions. The character of the fixed fittings in our laboratories has altered but little for many years, and it seems pertinent to inquire whether something could not be done by the use of alternative materials or by standardisation to reduce their cost.

I recently brought this matter to the notice of one of our learned societies, and received a very cordial reply from its council, which has referred the question to the Department of Scientific and Industrial Research; and I have reason to believe that this Department is proposing to take some action, in which event I have arranged that the Science Standing Committee of one of our Royal institutes shall be represented at any deliberations. Things, however, move slowly and time is passing, which must be my excuse for troubling you with this letter in the hope that the subject may raise some interest, and possibly lead to some constructive suggestions.

There are several obvious directions in which research on this subject, which should be neither particularly lengthy nor expensive, seem likely to be fruitful, but I must not encroach further by elaboration.

The Standard of Atomic Weights.

IN reply to the letter of Prof. J. R. Partington appearing in NATURE of April 29, it has already been announced in your columns that Dr. Aston has shown neon and chlorine to be each mixtures of two isotopes with atomic weights which are whole numbers, and I have suggested that the atomic weights of all the elements with low atomic weights are very approximately of the form $2x+a$, where x is the atomic number and a a small integer, and there are indications tending to show that a is independent of the chemical properties of the element (see NATURE, February 26, p. 704). For the lower atomic weights the calculation is not greatly affected whether the atomic weight of hydrogen or of oxygen is taken as the standard. With the exception of hydrogen, no atomic weight is less than $2x$, if the atomic weight of oxygen is taken as the standard. There is, accordingly, some justification for treating the atomic weights of helium, boron, carbon, nitrogen, oxygen, and fluorine as normal and that of hydrogen as abnormal. If, as appears to be the case, the atomic weights are not only variable, e.g. lead, neon, etc., but also contain a quantity independent of the chemical properties of the element, the determination of the relative atomic weights of two elements to a high degree of accuracy will in many cases be impossible, and in some others futile.

In some respects it might be convenient to take helium as the standard for atomic weights, this element certainly assisting in a few instances to build up the atomic weight, and as helium can now be prepared in large quantity the accurate determination of its density will not be so difficult as heretofore.

The Mole Cricket.

ONLY one British species of mole cricket is known, *Gryllotalpa vulgaris*. It is now becoming very rare in England. It is largely carnivorous, and by burrowing underground with its powerful fore-legs, which by a shear-like action cut through roots, it causes a certain amount of damage. It is by the peculiar

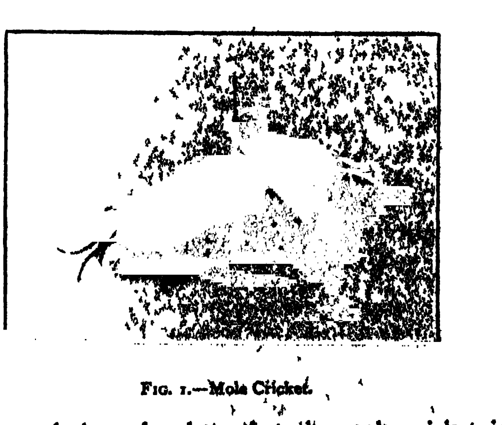

FIG. 1.—Mole Cricket.

structure of these fore-legs that the mole cricket is readily recognised and distinguished from all other insects. These legs are thicker, but shorter, than the hind-legs, each of the very short tibiæ ending below in four claws spread out like the fingers of a hand. The specimen represented in the illustration was caught at Send, near Woking, in Surrey, on March 15 last.

The Optophone: An Instrument for Reading by Ear.

By Dr. E. E. Fournier d'Albe.

The type-reading optophone, an instrument designed to enable blind people to read ordinary print, was described in Nature in 1914 (vol. xciv., p. 4). At the British Scientific Products Exhibition of 1918 some public reading demonstrations were given with a somewhat improved apparatus exhibited by the writer and by Mr. W. Forster Brown (see Nature, vol. cii., p. 10, September 5, 1918). These demonstrations sufficed to show that all the essential problems of type-reading had been solved, but the instrument then exhibited had certain defects which militated against its prolonged and convenient use by blind persons. Thus, the displacement along the line of type was effected by turning a handle, which no blind person would care to use by the hour. The construction of the apparatus generally was not sufficiently solid and substantial, in view of the fact that it had to be put into the hands of a necessarily somewhat clumsy operator.

After the close of the exhibition the construction of the instrument was undertaken by Messrs. Barr and Stroud, Ltd., of Glasgow, the well-known makers of range-finders and fire-control apparatus for the British and foreign navies. A great deal of thought and care has been bestowed upon the instrument by Dr. Archibald Barr, and the result has been a thoroughly sound, compact, and practical instrument, such as was shown by Dr. Barr in his lecture to the Royal Philosophical Society of Glasgow on March 24 last.

The general principle of the apparatus is shown by Fig. 1. A siren disc, D, is run at about 30 revolutions a second by means of the small magneto-electric motor shown. It contains five circles of square perforations, the innermost circle having twenty-four perforations, the outermost forty-two, the other circles being intermediate and corresponding to the relative frequencies of certain notes of the diatonic scale. A line of light in a radial direction is provided by the festoon lamp L, and the image of the filament of this lamp is thrown upon the print by a system of three lenses on the other side of the selenium tablet S. The axis of the concavo-convex lens C is slightly tilted out of the axis of the other lenses for a purpose which is specified below. The general result of the optical system is to give a line of luminous dots on the print, each dot having a different musical frequency. The light constituting these dots is diffusely reflected back on to the selenium, which is put in circuit with a battery and a high-resistance telephone receiver. Those dots which fall on white paper produce a note of their own musical frequency in the telephone, while those which fall on black are extinguished. We thus get what may be called a "white-sounding" optophone, in which the black letters are read by the notes omitted from the scale rather than by the notes which remain sounding. All the reading demonstrations hitherto undertaken have been given with a "white-sounding" optophone.

A modification of this principle, introduced by Messrs. Barr and Stroud in consultation with the writer, is the provision of a second selenium preparation in the form of a cylindrical rod, the top of which can be seen at B (Fig. 1). This rod receives the light reflected by the concave surface of the lens C, which produces a real image of the line of dots on a generator of the cylindrical rod, and by turning this rod about its axis the image can be made more or less effective as desired. By balancing the effect on B against the effect on S, when white paper alone is exposed, a silence can be produced in the telephone, and the effect of the passage of a black letter is to make a sound which varies in accordance with the formation of the letter. This is the principle of what may be called a "black-sounding" optophone, and

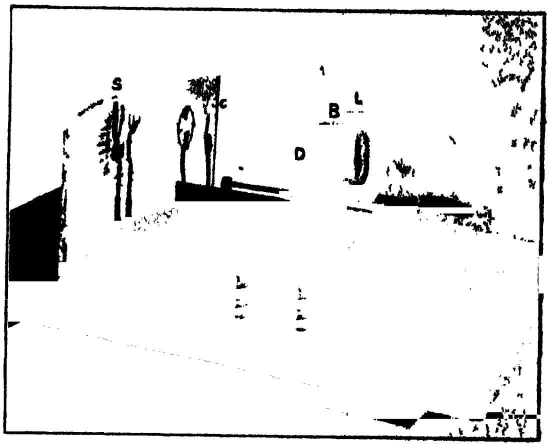

Fig. 1.—Skeleton apparatus showing the principle of the optophone.

although its advantage over the white-sounding type has yet to be proved, there is little doubt that the learning of the alphabet sounded on the new principle will be easier, though in the writer's opinion the ultimate speed acquired by either black-sounding or white-sounding will be approximately the same. It is interesting in this connection to note that Miss Mary Jameson, the blind girl who gave the demonstrations at the 1918 Exhibition, now reads habitually at a speed of about twenty-five words a minute with a "white-sounding" optophone made by Messrs. Barr and Stroud, and finds, indeed, that when the instrument is adjusted for a lesser speed reading becomes more difficult.

The present construction adopted by Messrs. Barr and Stroud is shown in Fig. 2. The disc, lamp, lenses, and selenium, as well as the motor, are all mounted in the swinging "tracer," which

can be brought over to the right by means of the reading-handle H. It then returns to the left with a slow, silent, and steady motion regulated by the worm gearing W, which drives a small paddle inserted in a viscous liquid. This paddle can be inserted more or less deeply into the liquid by the regulating nut R, and such is the range

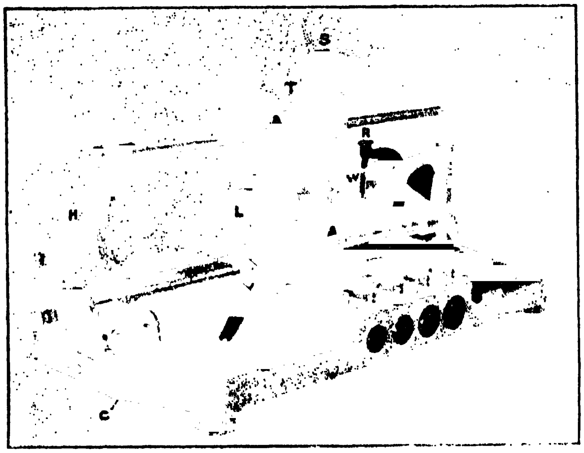

FIG. 2.—The optophone with book-rest removed.

of adjustment possible that a line can be read in anything from five seconds to five minutes, according to the proficiency of the reader. When the line is read, the next line is brought into focus by the change-bar C, which works a friction grip inside the bar on which the "tracer" is pivoted, and can be adjusted for any desired line space

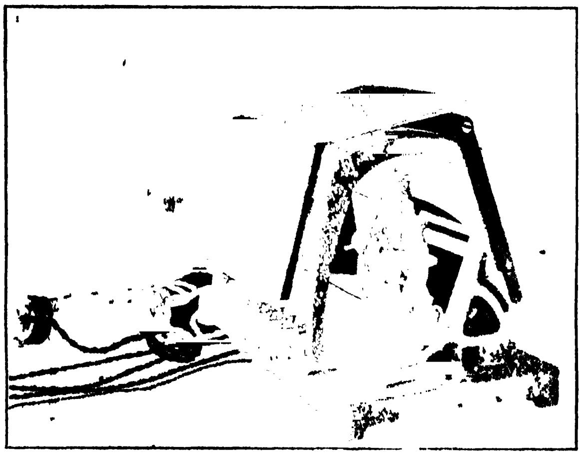

FIG. 3.—The optophone complete with book-rest.

by means of the screw attached to the change-bar. A lever attached to the "tracer" enables the operator to reverse this motion or to release the whole "tracer" from the friction gear, so that it may be quickly brought to the top of a page.

The festoon lamp is inserted at L, where it is held by a spring clip, and whence it can easily be removed for renewal even by a blind operator. The balancer is inserted at B, and can be adjusted for silence by means of the small handle shown.

Fig. 3 shows the apparatus from the top page end and with telephone and flex connections attached, as well as the book-rest R holding a book. The adapters of these flex connections are all of different sizes, and fit into different-sized holes in such a manner that they cannot be wrongly inserted—an important consideration with blind operators.

The various connections with their switches are for the motor, the lamp, and the two selenium circuits respectively. When the adapters are removed, a cover can be placed over the whole instrument, which clips on to the aluminium base, and the optophone can thereupon be carried about like a typewriter.

Fig. 4 shows the manner in which the instrument is manipulated by a blind person.

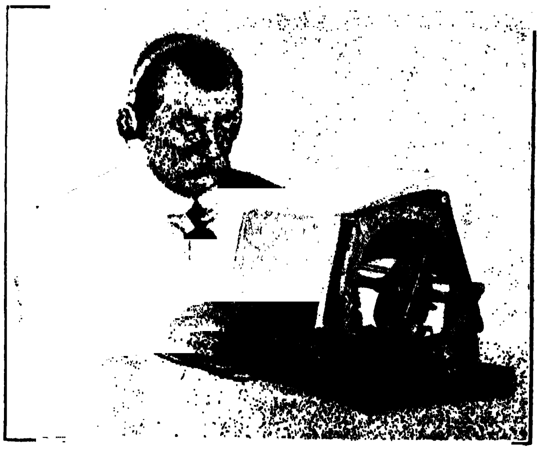

FIG. 4.—Line-changing with the optophone.

Special mention ought to be made of a contrivance for adjusting for various sizes of type. The middle lens of the three shown in Fig. 1 is mounted in a nut which can be screwed up and down within the "tracer" by means of two gaps cut in the upper cylindrical portion at T (Fig. 2). The nut is provided with six nicks across the rim, which enable a blind operator to count the number of turns of the nut, and thus to adjust for any definite size of type. This ingenious contrivance is, I believe, due to Dr. Stroud.

In practice it is found that, with the new apparatus, the various adjustments for size of type, length of line, and line interval are quite easily made by blind persons, and that the instrument, with all its delicate adjustments, can remain in use for a long time without anything getting out of order. It is therefore safe to say that the problem of opening the world's literature to the blind is now definitely solved.

The Kalahari and Ovamboland.

By PROF. E. H. L. SCHWARZ.

THE Kalahari and Ovamboland belong physiographically to one and the same province; the former is a region of red sand and the latter of white sand. The whole area, some 350,000 square miles, is blocked by an encircling ring of hard rocks, breached on the east by the Victoria Falls, on the south by the Aughrabies Falls on the Orange River, and on the west by the great cataract (300 ft. high) on the Cunene River. The consequence of this peculiarity is that the whole region is flat and the rivers have scarcely any fall, the floods seeping rather than flowing along the sandy river-beds and blocking up the channels with bars made of branches, reeds, and other rubbish, so that there has been a constant changing in the distribution of the water.

On the west there are two great depressions, the Makarikari and the greater Ngami. Livingstone obtained the impression that the two formed the bed of one enormous lake, but the map of Passarge shows the two very clearly defined. The greater Ngami is a depression elongated in a south-westerly direction, with parallel sides, and 300 miles long by 100 miles broad; part of the breadth in the northern half is occupied by sand dunes, so that the effective area is now less than that of Victoria Nyanza; but before it was tapped by the Zambezi it must have been a little larger. The Zambezi enters the depression at the Mambove Falls, follows the northern boundary, and leaves the old lake at Kasungula. It is not certain when the Zambezi first breached the wall and let out the waters of the lake; the Portuguese maps before Livingstone's time showed the river beginning not so very far above Zumbo, and we know that the Portuguese had a very good idea of the country so far back as the sixteenth century. The Falls cannot be of very great age, because the gradient below them is more than 15 ft. to the mile, and a great river like the Zambezi would have flattened out the gradient if it had been of any considerable age. The recent earthquake at New Langenburg, at the head of the Loangwa River, shows that the area is one of great seismic activity, so that the original idea of Livingstone and Murchison, that the crack was formed by

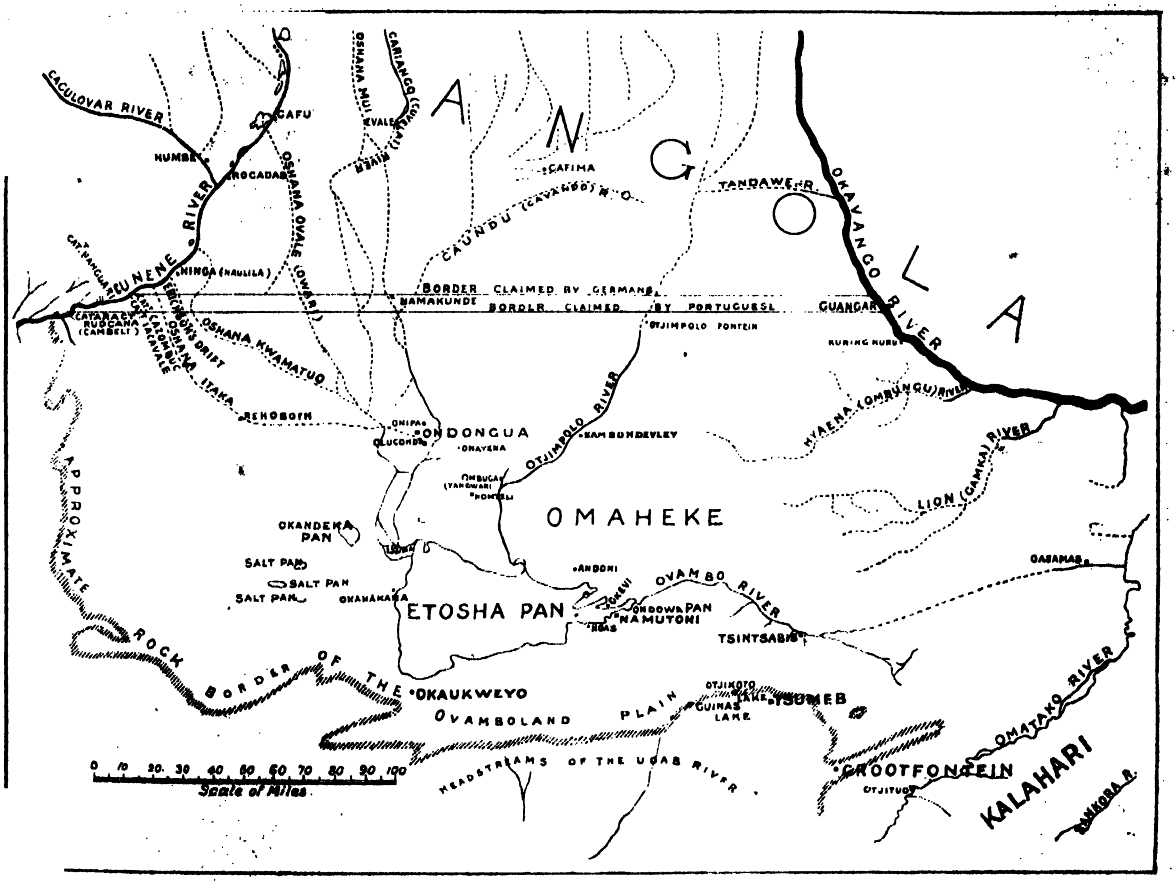

FIG. 1.

such agency, is worth reconsidering. Certainly the idea that the river has worked back along joints requires some modification, because the depth of the crack, reckoning from the top of the Falls to the bottom of the gorge, is more than 1100 ft., and joints do not penetrate so deep.

Two rivers fan out on the floor of the depression of the greater Ngami, in the same way that the Rusisi does on the plain on the north of Tanganyika, which has been exposed since the Lukuga tapped the lake and drew off the water; this last case, according to Arab accounts, has occurred within the last 500 years or less. The Ngami feeders are the Okavango and Chobe rivers. The Chobe flowed south in Chapman's time (1852), but the channel became blocked with reeds and rubbish below the Mababe swamp, and it now goes straight into the Zambezi. The Okavango until quite recently also flowed south into the Ngami of Livingstone, but a branch, the Selinda, has developed which takes the water into the Chobe and so into the Zambezi, and Ngami is now dry.

When the Chobe and Okavango rivers flowed south to Lake Ngami the water overflowed from that lake into the Botletle, which breached the eastern wall of the depression, and so made its way to the Makarikari. This depression has an area of 15,000 square miles and two "floors"; the Soa and Ntwetwe Pans form the lowest levels, while around are immense grass flats. We know fairly definitely that this dried up about 1820, thirty years before Chapman was there, and the Bushmen described to him how the whole expanse was then covered with dead hippopotamus and fish. Now the Botletle very seldom reaches the Makarikari, though the floors may fill for a few weeks from drainage from the east.

When the waters of the upper Zambezi were impounded in the Ngami depression, the water flowed south from the Makarikari into the Letwayo or Okwa, and found its way into the Molopo and so to the Orange River. According to traders who have crossed this part many times, the old channel can still be traced; certainly the lower Molopo has a bed far greater than would have been cut had it only carried the waters from the tributaries now shown to connect with it. The region between the Makarikari and the bend of the Molopo is the "Great Thirst"; the main routes through the Kalahari are now fairly safe and the Government has put down bore-holes for the accommodation of travellers, but it is still exceedingly difficult to explore away from the main tracks. The natural slope of the plain of the Kalahari is to the S.S.W., so that there was nothing to prevent the original river taking the course indicated; when the water was diverted to the Zambezi the area became a waste of sand. The French in the western Sahara have similarly shown that the ergs or sand deserts occupy the basins of former river systems.

Ovamboland is just a great level river plain, the ideal peneplain. Every part of it is covered with shallow depressions, sometimes connected, forming rivers; at others they are in parallel series of disconnected hollows, elongated in the direction of the nearest river. In between are sandy tracts covered with forest. In this there are a number of wide, open tracts, which form the main habitable areas, and each of these openings is occupied by a separate tribe of Ovambos. On the north there are the Cunene and Okavango rivers, which have built themselves above the plain, and in flood-time they overflow their banks and send the water down spillways which, in former years, filled up all the depressions and converted the country into a swamp; something like a third of the plain was then submerged. As the flood subsides, the crops, which are planted on series of little sand-hillocks, rapidly come to maturity in the damp, steaming atmosphere, the palms and morula-trees yield wine, and the lot of the Ovambo was then a pleasant one.

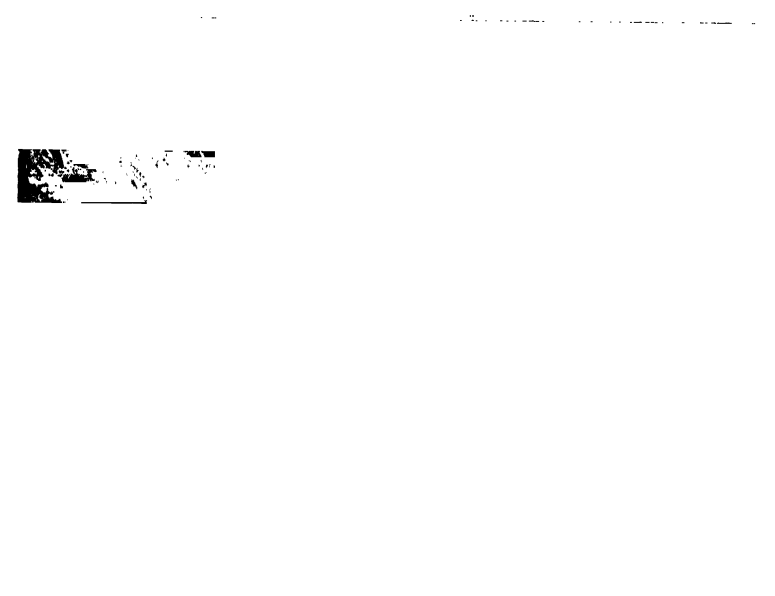

FIG. 2.—Rucana Cleft, Cunene River.

The spillways from the Okavango still carry water out from the river southwards, but not in sufficient quantity to reach any distance; and those from the Cunene are quickly diminishing. The rapid lowering of the beds of the main rivers by erosion has resulted in the desiccation of the country, and at no very distant date Ovamboland will become a land of the "Great Thirst" like the Kalahari. The conversion of an area of

70,000 square miles from the condition of a tropical swamp, similar to the Bahr-el-Ghazal, into a wilderness of dead trees and withered grass has had a very bad effect on the climate of South Africa, and the consequences are noticeable north as well as south of the Zambezi; the completion of the process is a matter of a few years only. What has happened in Ovamboland occurred in the Makarikari a hundred years ago, and in the central Kalahari not so very long before that; so, section by section, this great area has lost its water-supply, and between 300,000 and 400,000 square miles of country have become desert within comparatively recent times.

The spillways from the Cunene on one side, and those from the Okavango on the other, connect in the great depression to the south, the Etosha Pan. This is a "floor," like the Soa and Ntwetwe Pans, only here there is no trace of brak, the level pan being covered with a dark green film due to microscopic plants which turn a yellowish-green when moistened with water from a thunderstorm. Very little water finds its way into the pan down the river channels nowadays. The grass flats round the pan are some 5 ft. above the level of the floor, and are often black with zebras, wildebeests, gemsbok, koodoos, and springbok, with the attendant lions. The late Mr. J. W. F. Breijer was game ranger at the time of my visit, and it is due to his tireless efforts to suppress poaching that the game has returned to the district; to him also I owe the tracing of the Lion River, a spillway from the Okavango to the Etosha, thus completing the through connection of the Cunene and Okavango rivers.

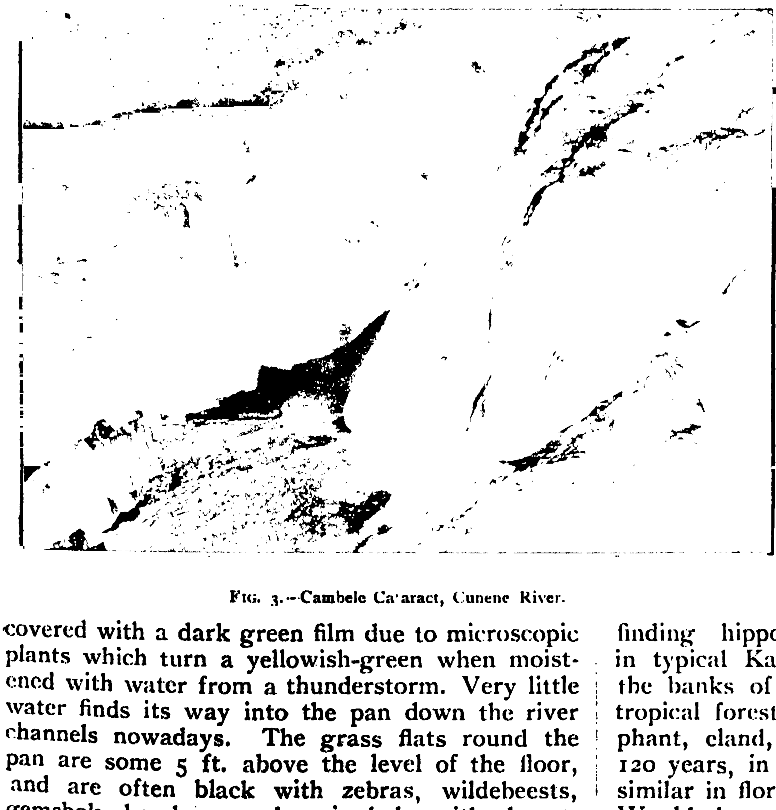

FIG. 3.—Cambele Cataract, Cunene River.

The restoration of the Kalahari and Ovamboland plains by weiring up the outlets on the north and turning the waters of the Cunene on one hand, and of the Okavango and Chobe rivers on the other, would convert these countries into habitable regions once more. Both rivers are necessary, for the one reinforces the other. Ovamboland would be converted into a swamp, a condition of affairs which the natives are accustomed to and thrive on; as it is, they are always on the verge of starvation, and in 1915–16 thousands did die of starvation, and their bones are strewn for 200 miles along the road from Ondongua to Tsumeb, the terminus of the railway, where they had expected to get food and work. Ovamboland is not suitable for white settlement, but from the evaporation from this vast swamp the rivers, like the Zambezi and Okavango, would be reinforced at their sources, and their diminishing volume converted into an increasing one. The Kalahari, on the other hand, is eminently suited for white settlement; with water anything will grow; cotton is indigenous and would form the summer crop as in Egypt; wheat grows as a winter crop, and mealies (maize) as an autumn one. Away from the actual irrigation furrows the ranching possibilities are enormous. The country is now nominally under Bechuana chiefs; but, while every consideration can be paid to their wants, a meagre population of 150,000 natives cannot indefinitely hold up a country of 300,000 square miles. White settlement could proceed without interfering in any way with the natives, as there is room enough for all.

The effect on the climate of South Africa is another matter. We know that hippopotamus swarmed all over the Karroo in not very distant times, for their bones are dug up all over it in the dry river-beds. Before the Makarikari went dry in 1820, Barrow, Lichtenstein, and Le Vaillant described finding hippopotamus in enormous quantities in typical Karroo country like Cookhouse, and the banks of the rivers were clothed with subtropical forest, in which roamed rhinoceros, elephant, eland, etc. The Karroo within the last 120 years, in the eastern portion, was a country similar in flora and fauna to British East Africa. Would the restoration of the Kalahari affect the Karroo? The lost lakes formed the end of the series of great lakes in Central Africa, and the function of these latter is to provide moisture for the inland regions. The central areas of Africa lie so high that moisture blown in from the sea is dropped on the edge by the diminution of pressure, and very little is left for the centre from these sources. With the Kalahari lakes restored and the vegetation once more established, it seems reasonable to suppose that the effect will be the same as that produced by the great northern lakes on their neighbouring regions.

The Royal Academy.

EVERY critic of the Royal Academy finds material for praise or for condemnation from whatever point of view he regards the works exhibited, and the scientific visitor is no exception to this rule. Indeed, it is impossible that among so large a number of works all should be of the same high order of merit as are the few produced by master hands. From the scientific point of view it is not difficult to divide the sheep from the goats—the true representations of Nature from the grotesquely unreal. It may be presumed that the perpetrators of the latter type of work visit the Academy and there study the pictures of their fellow-artists. If this be so, it is astonishing that they should continue from year to year to produce unreal caricatures of natural objects, when often in close contiguity to their pictures are to be seen beautiful representations of the same type of scenes, truthful to life in every particular, and gaining immeasurably thereby. The fact that both obtain admittance to Burlington House must be taken to demonstrate that both are of artistic merit, but there the similarity ends.

An example of this contrast in methods of dealing with a subject may be found in this year's exhibition by comparing "Off the Land" (38) with "Sunset at Sea" (347). Both show sea and sky scenes. The former gives a perfectly natural representation of light from the sky reflected in the sea, while in the latter an intensely red sunset sky meets at the horizon an intensely blue sea, a condition unlikely to obtain while water possesses its normal powers of reflection. The effect is so entirely unnatural that it is difficult to believe, without reference to the title, that the lower part of the picture is meant to represent water at all. In Gallery No. III., on either side of the chief centre piece, with which the scientific critic is not concerned, are two pictures of yacht racing which form an interesting contrast. When looked at from near-by the one is wholly delightful, while the other is spoilt by its crude sky. When, however, a view is taken from a considerable distance, the two pictures appear of more equal merit. The contrast between the two methods of treatment is brought out strikingly by the juxtaposition of the pictures, be it accidental or otherwise.

A feature of the present exhibition which will strike the visitor is the extraordinary sea-colouring in several of the works, though examination of the catalogue shows that for this a single artist is largely responsible. One case has already been cited. To mention one other from among several examples, it would be very surprising to meet in Nature with the contrasts in colouring depicted in "The Sunken Reef" (177). The writer has not had any opportunity of studying dazzle-painted ships in their natural surroundings, but if in the work "In the Narrow Seas" (200) Mr. Norman Wilkinson has given a correct representation of the effect produced—and there seems no reason to doubt that this is the case—it is well brought home to the landsman how baffling the effect must have been to the commanders of enemy submarines. In "The Forerunner" Leonardo da Vinci is seen showing a model of his flying machine to Ludovico Sforza, Duke of Milan, and his Court. Some of the spectators look amused, and for this the modern airman will find little difficulty in forgiving them. Several of Leader's beautiful scenes are exhibited. In studying "An Autumn Evening" (139) one wonders what object outside the picture casts a shadow over the lower part of the trees, while the upper part is illuminated with an evening glow; but there is no temptation to doubt the truthfulness of the portrayal.

J. S. D.

Obituary.

CAPT. E. W. CREAK, C.B., F.R.S.

CAPT. ETTRICK WILLIAM CREAK, who died in his sleep on April 3, was the son of the late Commander William Creak, of Norfolk, and a nephew of Sir H. Havelock, of Lucknow fame. He joined the Navy in the navigating branch of that Service about the year 1849, and served in various ships afloat until he was selected in 1868 to serve as an assistant in the compass department of the Admiralty. His service afloat was distinguished not only by his nautical acquirements and the remarks he sent from time to time to the Hydrographer, for which he was specially thanked in 1866, but also by his knowledge of French and music, rather rare acquirements in those days. He was able to add to our knowledge of some unsurveyed localities by his study of surveying operations, particularly by a plan of Ngaloa Bay, in the Fiji Islands, when serving in H.M.S. *Esk* about 1866. About this time Capt. Creak turned his attention to the errors of the compass on board certain ships which had traversed a great range of magnetic latitude, which inquiry was embodied in a report to the Admiralty and published by the Board of Trade. This marked him out as a suitable officer to be employed in the investigation of compass errors in H.M. ships, which were being increasingly constructed of iron and steel. For his services in the compass department and his magnetic reports he was made a fellow of the Royal Society in 1885, and he became superintendent of the Admiralty compass department in 1887.

Capt. Creak took an active part in the determination and control of the constants required for

the reduction of the magnetic observations made by the *Challenger* expedition, 1872–76, during which expedition it was discovered that the coral islands of Bermuda lay over a magnetic field in which the variation of the compass differed as much as 6°, viz. from 4° W. to nearly 10° W., the true variation of the needle being 7° W.; this was ascertained by swinging the *Challenger* on every point in deep water close to the islands, and this process was continued on board that vessel in many other parts of the world, where the true variation was affected by local attraction on shore, so that the results of the shore observations were not trustworthy; but the *Challenger* being a wooden vessel, although not entirely free from iron in her construction, better results were obtained by swinging her in deep water near the land. The results of the *Challenger* observations are published in vol. ii. of the official narration of the voyage, and in vol. ii. of the reports on the physics and chemistry of the expedition, where plans, constructed by Creak, are given of the magnetism observed at the Bermuda Islands, and also charts of the variation, inclination, horizontal force, and vertical force for the epoch 1880, constructed mainly from the *Challenger* observations, combined with all other observations available to the date of publication.

Capt. Creak pointed out in his magnetic contributions that at certain positions in the world magnetic shoals exist which affect the compasses of vessels sailing over those shoals. One such shoal near Cossack, in North Australia, was crossed by H.M. surveying vessel *Meda*, in a depth of 8 fathoms, with two shore objects transit, and the compass needle was deflected 30° for about one mile.

At Funafuti, another coral atoll in the Pacific, in lat. 8° 30′ S., long. 179° 12′ E., another magnetic field exists, where the variation changes nearly 2°, and the dip 1°, in different localities, as shown by the magnetic survey of the atoll made by Admiral Sir A. Mostyn Field in H.M.S. *Penguin* in 1896, the results being investigated by Capt. Creak, and published by the Royal Society in 1904. Capt. Creak also instructed the officers engaged in the Arctic expedition of 1875–76 under Capt. G. S. Nares, R.N., and prepared the directions and magnetic charts for the "Arctic Manual," 1875. He also prepared the magnetic instructions for the Antarctic expedition of 1901. When, owing to his having reached the age of fifty-five, he had to retire from active service afloat in 1890, and to his not having served the number of years afloat to entitle him to be retired with the rank of captain, a special Order in Council was issued giving him that rank, so that his important services in the compass department should not deprive him of the honour he would have received had he served the requisite number of years at sea.

During Capt. Creak's service in the compass department the late Lord Kelvin invented a compass superior to that then in use in H.M. ships, which was adopted by the Admiralty; but, owing to the increase in the size of the guns in H.M. ships, this compass was eventually discarded for a liquid compass brought out by Capt. Creak, which is now the standard instrument afloat, and is furnished with a special azimuth circle for use in torpedo-boats, destroyers, etc., all other compasses having failed to stand the vibration and motion and the gunfire in these vessels. He also brought out a simple form of instrument for correcting by magnets the heeling errors, and invented the Lloyd-Creak dip and intensity apparatus, originally meant for observations afloat, but which has been found very useful also on shore. This instrument was fully described in *Terrestrial Magnetism* for October, 1901.

In 1903 Capt. Creak was president of the geographical section of the British Association, and in his presidential address at Southport in that year gave an interesting account of the progress of our knowledge of magnetism both afloat and ashore up to that time, which was published in the Proceedings of the British Association, and also in the *Geographical Journal*, vol. xxii., 1903. He was made a C.B. in 1901, in which year he was retired from the compass department at the age of sixty-six. Capt. Creak also assisted the late Sir Frederick Evans and Mr. Archibald Smith in preparing and publishing the "Elementary Manual for the Deviations of the Compass in Iron Ships" in 1870, and after the death of Sir F. Evans later editions of that manual were entirely prepared and published by Capt. Creak. In the ninth edition prepared by him in 1895 the question of heeling error and its correction was specially discussed, and tables were given to assist in the correction of quadrantal deviation and the application of the Flinders bar, etc.

T. H. T.

SIR EDMUND GILES LODER, BART.

THE death of Sir Edmund Loder at the age of seventy removes from the ranks of English country gentlemen one of the cultivated members of that class. Possessed of ample means and abundant leisure, Sir Edmund devoted his youth and middle age to field sport and travel in many lands. In the pursuit of big game in four continents his fine marksmanship enabled him to make the very large collection of horned and other trophies now preserved at Leonardslee. He was among the last of British sportsmen to take toll of the dwindling herds of bison in North-west America, and the first European to obtain a specimen of the little desert antelope, named after him, *Gazella Loderi*, which inhabits the Sahara contentedly without access to water.

Were that all, it would scarcely serve to raise Sir Edmund Loder above the common ruck of big-game shooter and globe-trotter; but he possessed and exercised the gift of accurate observation, enabling him to acquire much sound knowledge of the habits of wild animals, and to distinguish their specific affinities. Unfortunately, he had

not the knack of recording his experience. Not only was he destitute of all turn for literature, but the mere act of putting pen to paper was intolerably irksome to him. This is the more to be regretted, because the few papers on zoology and botany which he contributed to scientific journals contained sound, and sometimes important, information.

Sir Edmund's indolence in this respect had no counterpart in his botanical work, for he took infinite personal pains in the delicate operation of hybridising rhododendrons. His crowning achievement in that line has been the magnificent cross between *R. Griffithianum* and *R. Fortunei* which appropriately bears the name *R. Loderi*, and is generally admitted to be the grandest hardy hybrid hitherto raised in that genus. The collection of conifers which he formed and grew at Leonardslee contained more species than any other in the United Kingdom.

Only a few weeks before Sir Edmund's death the present writer spent an afternoon with him in the wonderful landscape he had created at Leonardslee. The early Asiatic rhododendrons were already ablaze; there was no warning in that fair scene; but now comes Horace's dirge irresistibly to mind:—

Linquenda tellus et domus et placens
Uxor, neque harum quas colis arborum
Te, præter invisas cupressus,
Ulla brevem dominum sequetur.

HERBERT MAXWELL.

PROF. WILHELM PFEFFER, FOR.MEM.R.S.

W. PFEFFER, who died on January 31 last at Leipzig, was born in 1845 near Cassel, the son of an *Apotheker*; he studied at a number of German universities, his Ph.D. being taken at Göttingen. He was first a Privatdozent at Marburg, then assistant-professor at Bonn, and later full professor at Basel, in Switzerland. In 1878 he went to the University of Tübingen, and in 1887 to the University of Leipzig, where he remained for the rest of his life. He was elected a foreign member of the Royal Society in 1897. Pfeffer may be associated with Sachs as the founder of modern plant physiology. He and the late Prof. Strasburger, of Bonn, were for a long time the two best-known German botanists, and for many years they drew to their respective laboratories numerous foreign workers, particularly from the United States. Pfeffer was the author of many scientific papers, but he is perhaps best known for his "Pflanzenphysiologie," of which the first edition appeared in 1880, and the last part of the second edition in 1904; the second edition was translated into English. This handbook was a truly monumental work, in which a wealth of material was dealt with with great critical insight; hence it was for many years the standard and invaluable reference book on the subject. Pfeffer's work in 1877 on osmotic pressure, which laid the foundation of our more exact knowledge of that phenomenon, must also be referred to. With his death the three outstanding figures of the older German botany—Sachs, Strasburger, and Pfeffer—have all passed away.

V. H. B.

IT is with much regret we learn of the death, on February 20, of MR. MAXWELL HALL, Government Meteorologist of Jamaica. Mr. Maxwell Hall was a barrister-at-law and resident magistrate for the district of Hanover. His interest in meteorology has placed the knowledge of the weather of Jamaica on a better basis than that of any other West Indian island. He succeeded in establishing a weather service in Jamaica in 1880, the objects being to encourage the recording of rainfall and to foretell the approach of hurricanes. In 1911 rainfall records were available from 194 stations, with observations at each for at least ten years. It is hoped that this fine record of work will not be interrupted by the death of its originator. For upwards of thirty years Mr. Maxwell Hall was a fellow of the Royal Meteorological Society.

THE death is announced of LORD GUTHRIE, one of the senators of the College of Justice in Scotland, at seventy-one years of age. Charles John Guthrie was admitted to the Faculty of Advocates in 1875, and, after a successful career at the Bar, was appointed a Judge in the Court of Session in 1907. Lord Guthrie was for a time president of the Royal Scottish Geographical Society and chairman of the Early Scottish Text Society. His interest in antiquities led to his election as member of the councils of the Antiquarian and Scottish History Societies. He was joint author of the memoirs of his father, the Rev. T. Guthrie, D.D., founder of the Ragged Schools and editor of the *Sunday Magazine*. In the world of literature he will be best remembered as a friend in youth of Robert Louis Stevenson, of whose nurse, "Cummy," he published an appreciation in 1914.

MEMBERS of the British Association who have attended any meeting for many years past will learn with regret of the death of MR. H. C. STEWARDSON, the chief clerk and assistant treasurer. Mr. Stewardson's record of devoted work was particularly notable. He entered the service of the association in 1873, being encouraged to do so by William Spottiswoode, president of the association in 1878, to whom he was apprenticed in the printing business. The annual reports of the association owe much to his careful reading and indexing, and he was also specially concerned with the work of the Corresponding Societies Committee, and compiled its valuable annual catalogue of communications to local scientific societies. Mr. Stewardson was a member of the Stationers' Company.

THE RIGHT HON. SIR THOMAS W. RUSSELL, Vice-President of the Department of Agriculture and Technical Instruction for Ireland from 1907 to 1918, died on May 2 in his eightieth year.

Notes.

THE first conversazione of the Royal Society this year will be held in the rooms of the society at Burlington House on Wednesday evening next, May 12.

A SUMMER meeting of the Institution of Naval Architects will be held in Liverpool on July 6–8. Meetings for the reading of papers will be held, and arrangements will be made to visit some of the principal shipbuilding and other works in Liverpool and its vicinity.

SIR HENRY A. MIERS, Vice-Chancellor of the Victoria University of Manchester, has been re-elected president of the Manchester Literary and Philosophical Society for the session 1920–21. Dr. H. F. Coward and Prof. C. A. Edwards have been elected honorary secretaries.

A PUBLIC meeting, arranged by the National Union of Scientific Workers, will be held on Tuesday next, May 11, at 8.30 p.m., at the Imperial College Union, Prince Consort Road, South Kensington, for the discussion of "The Economic Position of Scientific Workers." The chairman will be Dr. H. M. Atkinson, and the subject will be introduced by Prof. J. B. Farmer and Dr. J. W. Evans.

SIR HENRY BIRCHENOUGH has been appointed chairman of the British Dyes Corporation in succession to Lord Moulton, whose resignation is announced. Sir Henry was chairman of the Royal Commission on Paper, 1917; of the Committee on Cotton-growing in the Empire, 1917; and of the Advisory Council to the Ministry of Reconstruction, 1918.

A COMMITTEE of fellows of the Royal Society and members of the University of Cambridge has been formed for the purpose of collecting funds for a memorial to be erected in Westminster Abbey to the late Lord Rayleigh in recognition of his eminent services to science. Lord Rayleigh was both president of the Royal Society and Chancellor of the University, and an appeal has been issued by the society and the University. It is thought, however, that there may be some men of science unconnected with either of these bodies who may wish to show their appreciation of Lord Rayleigh's work. Donations may be sent to the hon. treasurers of the fund, Sir Richard Glazebrook and Sir Arthur Schuster, at 63 Grange Road, Cambridge.

THE council of the Institution of Civil Engineers has made the following awards for papers read and discussed during the session 1919–20:—Telford gold medals and Telford premiums to Mr. David Lyell, Mr. J. K. Robertson, and Major-Gen. Sir Gerard M. Heath; a George Stephenson gold medal and a Telford premium to Mr. Maurice F. Wilson; a Watt gold medal and a Telford premium to Mr. P. M. Crosthwaite; and Telford premiums to Major E. O. Henrici, Sir Francis J. E. Spring, Mr. F. O. Stanford, Mr. J. Mitchell, Mr. J. W. Sandeman, and Dr. A. R. Fulton.

LT.-COL. SIR LEONARD ROGERS, I.M.S., has recently returned from India on a year's leave on medical certificate, on the expiry of which he will have only a short period of Indian service remaining before being retired under the age rules. As he has completed the organisation of the Calcutta School of Tropical Medicine for opening next autumn with a full staff, he does not propose to return to India, but to devote himself to continuing his researches on the treatment of tuberculosis, which have already yielded some promising results in India, and have arisen out of his successful method of treating leprosy by injections of soluble preparations of the unsaturated fatty acids of various oils.

AT the annual general meeting of the Marine Biological Association, held in London on April 28, Sir E. Ray Lankester was re-elected president of the association, and Sir Arthur Shipley chairman of council. The Rt. Hon. Sir Arthur Griffith-Boscawen was added to the list of vice-presidents, and Messrs. T. H. Riches and Julian S. Huxley became members of council for the first time. The council reported that donations amounting to 1770*l.* had been promised towards the erection of new laboratories and the equipment of a department of general physiology. Scientific work at Plymouth during the year had been specially directed to a comparison of the condition of the trawling grounds with that which had been observed before the war, to the continued study of the distribution of post-larval and young adult stages of fishes and the food eaten by fishes when in these stages, and to observations on the invertebrate fauna, particularly on the rate of growth of various organisms.

THAT the Plumage Bill was "talked out" in the House of Commons last Friday is probably due to the fact that it did not come before the House until the day was far spent. As a private members' Bill, its chances of success, should the debate be resumed on some future Friday, are not great. The Hon. E. S. Montagu spoke briefly, and to the point, in its favour, remarking that the Government was extremely anxious to see the Bill passed into law. He did not believe, he said, that the passing of the measure would destroy any legitimate trade. Lord Aberdeen's Bill, which is on its way to the Commons, affords yet another chance, though a slender one, for necessary legislative action. It does not seem to be realised, even by zoologists, that the matter is one of real urgency, not merely for ornithologists, or for those who desire to protect birds for their own sake, but for all who are concerned with problems of economic zoology and pure science. It is therefore devoutly to be hoped that this matter will at once be taken up by men of science in all seriousness. Their considered opinion is necessary if any Bill restricting the import of plumage of wild birds is to become law before extermination has set its seal upon a number of species which are well within the "danger-zone."

THE need has long been felt for a corporate body analogous to the Institute of Chemistry which would represent the profession and strengthen the position of workers engaged in physics, and would also form a bond between the various societies interested. The

Institute of Physics has been founded for this purpose by the co-operation in the first instance of the Faraday Society, the Optical Society, and the Physical Society of London; and the first board is constituted from representatives appointed by the councils of these societies. It is hoped that in the course of time other societies will associate themselves with the institute. There will be three classes of members: Ordinary members, associates (A.Inst.P.), and fellows (F.Inst.P.). Only the two latter classes, membership of which will require full professional qualifications, will be corporate members. The institute has already received promises of support from leading physicists, and the initial expenses are covered by a guarantee fund amounting to more than 1200*l.* The first president of the institute is Sir Richard Glazebrook, Sir Robert Hadfield is treasurer, and Prof. A. W. Porter honorary secretary. The other members of the board are:—Dr. H. S. Allen, Inst.-Commander T. Y. Baker, R.N., Prof. F. J. Cheshire, Dr. R. S. Clay, Mr. W. R. Cooper, Prof. W. H. Eccles, Major E. O. Henrici, Dr. C. H. Lees, Mr. C. C. Paterson, Major C. E. S. Phillips, Dr. E. H. Rayner, Mr. T. Smith, and Mr. R. S. Whipple. Mr. F. S. Spiers has been appointed secretary to the institute, and further particulars and forms of application for membership may be obtained from him at 10 Essex Street, Strand, W.C.2.

DURING the last ten years important research work on the corrosion of metals, and particularly on condenser tubes, has been carried on by the Corrosion Research Committee, which was founded under the auspices of the Institute of Metals. Very considerable progress in the study of this difficult subject has been made by the investigators acting under the direction of the committee, and the five reports which have been issued contain most valuable information, both as to the factors which influence corrosion and as to the methods of preventing corrosion, especially in the case of marine condenser tubes. The financial support of the investigations has been provided partly by the Institute of Metals and partly by the makers of tubes and of condensers. More recently a grant has been received from the Department of Scientific and Industrial Research. The cost of the investigations is, however, considerable, and the committee now makes an appeal for further funds from the users of tubes and condensers, who are equally interested in the question with the manufacturers. The continuance of a Government grant is contingent on a sufficient sum being provided by persons interested in the research. The persons affected by the work include shipbuilders and shipowners and also the insurers of ships, and it is hoped that a sum of something like 1000*l.* per annum can be raised from this source. Particulars of the work may be obtained from the secretary of the Institute of Metals, 36 Victoria Street, Westminster, London.

AT the annual general meeting of the Institution of Civil Engineers held on Tuesday, April 27, the result of the ballot for the election of officers for the year 1920–21 was declared as follows:—*President:* Mr. J. A. Brodie. *Vice-Presidents:* Mr. W. B. Worthington, Dr. W. H. Maw, Mr. C. L. Morgan, and Mr. Basil Mott. *Other Members of Council:* Mr. E. A. S. Bell, Dr. C. C. Carpenter, Col. R. E. B. Crompton, Mr. M. Deacon, Sir Archibald Denny, Bart., Sir William H. Ellis, Mr. A. Gordon, Mr. W. W. Grierson, Sir Robert A. Hadfield, Bart., Sir Brodie H. Henderson, Mr. E. P. Hill, Mr. G. W. Humphreys, Mr. Summers Hunter, Mr. H. G. Kelley, Mr. C. R. S. Kirkpatrick, Mr. J. Marchbanks, Mr. H. H. G. Mitchell, Sir Henry J. Oram, Mr. F. Palmer, Capt. H. Riall Sankey, Sir John F. C. Snell, Mr. W. A. P. Tait, Mr. A. M. Tippett, Mr. E. F. C. Trench, Prof. W. H. Warren, and Sir Alfred F. Yarrow, Bart. This council will take office on the first Tuesday in November next.

THE annual meeting of the members of the Royal Institution was held on May 1, Sir James Crichton Browne, treasurer and vice-president, in the chair. The annual report of the Committees of Visitors for the year 1919, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report of the Davy Faraday Research Laboratory Committee was also read. Sixty-four new members were elected during the year, and sixty-two lectures and nineteen evening discourses were delivered. The following gentlemen were unanimously elected as officers for the ensuing year:—*President:* The Duke of Northumberland. *Treasurer:* Sir James Crichton Browne. *Secretary:* Col. E. H. Hills. *Managers:* Dr. Horace T. Brown, Mr. J. H. Balfour Browne, Mr. J. Y. Buchanan, Mr. Burdett-Coutts, Sir James J. Dobbie, Dr. J. Dundas Grant, Dr. Donald W. C. Hood, the Right Hon. Earl Iveagh, Mr. H. R. Kemps, Sir Ernest Moon, the Hon. Sir Charles Parsons, Sir James Reid, Bart., Sir Ernest Rutherford, the Right Hon. C. Scott-Dickson, and Sir Henry Wood. *Visitors:* Sir Hugh Bell, Bart., Sir William H. Bennett, Mr. W. R. Bousfield, Mr. J. G. Bristow, Dr. Frank Clowes, Mr. Montague Ellis, Mr. W. E. Lawson Johnston, Mr. J. R. Leeson, Mr. T. B. Lightfoot, Mr. F. K. McClean, Mr. W. S. Norman, Mr. H. M. Ross, Mr. J. Shaw, Mr. T. H. Sowerby, and Sir Almroth Wright.

AT the anniversary dinner of the Royal Academy of Arts, held on May 1, the president, Sir Aston Webb, in proposing the toast of "Science," remarked that to science and scientific research in medicine and surgery they were indebted for the marvellous record of freedom from disease and saving of life which was one of the most wonderful and gratifying chapters in the war. To the physicist and engineer were due much of the work done in connection with aircraft, tanks, submarines, and guns, the wonderful work done in sound-ranging for submarines, the location of aircraft and guns by sound; but it was impossible to give any list of all that was done, and still less the names of the men of science who thus helped their country in its time of urgent need. The president coupled the toast with the name of Sir Joseph Thomson, who, in replying, said that the qualities of mind

that were called into play by the artist were in many respects identical with those used by the man of science. Imagination and observation were vital to scientific discovery. The artist and the man of science were concerned with the same subject—the study of Nature under various aspects. While it was vital for the progress of this country that the application of science to industry should receive every encouragement and assistance, yet they ought not to neglect those who, forsaking the trade routes of the great liners, steered their little ships to uncharted seas to bring back to us the golden fleece.

SIR JAGADIS BOSE gave a very interesting lecture at the University of London Club on Thursday evening, April 29, on his well-known experiments on movements in plants. He has applied the methods of instrumental physics to the study of tropic plant movements, and, beginning with methods which magnified the growth one hundred times, has finally, with his high magnification crescograph, reached magnifications of more than ten million. This instrument uses the principle of a fine magnetised lever affecting a magnetic needle and so demonstrating growth by the movement of an attached mirror. By this method very delicate growth responses of the plant could be shown, and its relative sensitivity under different conditions compared. One of the lecturer's most general conclusions was that indirect stimulus causes an increase of growth, while direct stimulus of a plant organ causes a decrease of growth or contraction. In this way positive, negative, and neutral responses to gravitation or light on the part of any organ were explained as the result of various combinations of response to direct and indirect stimulus. Sir Jagadis Bose's crescograph is so remarkably sensitive that doubt was recently expressed as to the reality of its indications as regards plant growth; and the suggestion was made that the effects shown by it were due to physical changes. A demonstration at University College, London, on April 23, has, however, led Lord Rayleigh and Profs. Bayliss, V. H. Blackman, A. J. Clark, W. C. Clinton, and F. G. Donnan to state, in the *Times* of May 4: "We are satisfied that the growth of plant tissues is correctly recorded by this instrument and at a magnification of from one to ten million times." Sir seen similar demonstrations elsewhere, give like testimony that the crescograph shows actual response of living plant tissues to stimulus.

FURTHER news from Capt. Roald Amundsen confirms the belief expressed in NATURE of April 22 and 29 that he had not abandoned his North Polar journey. His object in calling at Nome, Alaska, in July is evidently to secure more supplies, add to his crew, and to receive mails. A long despatch published in the *Times* of May 1 gives some details of the fortunes of the expedition and explains the change in plans. The *Maud* left her winter quarters in the Nordenskjöld archipelago west of Cape Chelyuskin as late as September 12, 1919. It was necessary to blast a channel through about one and a half miles of solid floe six to nine feet thick. Until the Taimir peninsula was cleared pack offered some obstruction, but to the eastward the sea proved to be fairly open. The lateness of the season was in Amundsen's favour in this part of his journey, and he was no doubt trusting to former accounts of open water in September. The *Maud* sailed east through Laptev Strait between the New Siberia Islands and the mainland and then turned north-east for Jeannette Island, but was stopped by tight pack in lat. 73° N. Amundsen made fast to the floes, intending to begin his drift, but on finding that the pack was nearing south he had to abandon his attempt. He decided to winter on the coast of Siberia, and after a passage rendered dangerous by ice and darkness reached Aion Island, Chaun Bay. One member of the expedition spent the winter with the Chukchee, who inhabit the interior of this part of north-eastern Siberia, in order to study their customs. Two men sent overland to the small trading village of Nizhne-Kolimsk with despatches for home turned back at Sukharnoe, a village at the mouth of the Kolima, with news that all communications with Europe were cut off. Amundsen hopes to reach Nome in July or August, and, if not too late in the season, to return north and enter the ice about Wrangel Island for his five years' drift.

WITH reference to the note in NATURE of April 15, p. 210, upon the laboratory of applied psychology connected with a well-known institute of mind-training, the director informs us that the fees charged are very considerably less than the cost of the tests performed or the scientific advice given, and that the laboratory is projecting the publication of research papers giving details of the work done, so that the world of science in general will be able to examine the methods adopted and the results obtained.

WITH the return to peace the increased cost of production has made it necessary to devise a new scheme for the publication of the "Victoria History of the Counties of England." Hitherto no order for fewer than ten volumes relating to a single county has been accepted, but it has been found by experience that there is a considerable demand for separate articles on special subjects. It has therefore been decided to issue the History, both that portion which has already been published and the remainder which is in preparation, in separate parts. Each part will include a single hundred, wapentake, or borough, and persons interested in the history, archæology, or economics of a special area will be able to procure what they require within a single cover. The new arrangements seem well adapted to popularise a work which has already taken the rank of a standard authority on the subjects with which it deals.

SIR THOMAS MUIR, the well-known mathematician, and until lately Superintendent-General of Education in Cape Colony, has recently made a splendid gift to the South African Public Library, Cape Town. It consists of about 2500 books and pamphlets, collected by the donor in the course of many years, and it includes a number of serials, sets of which are now almost un-

procurable. As might be expected, there is an unusually complete group of works on determinants and allied topics. The gift is of special interest because it is made to a *public* library. Several of our college and university libraries have been enriched by similar donations (*e.g.* there is the Graves collection at University College, London). The time has come when we may hope that the reference departments of our rate-supported town libraries will be strengthened in a similar way. Of course, mathematics is not the only subject deserving attention; natural science, history, archæology, economics, etc., all have a claim to be considered. Anyone who cares to examine the present record of public research libraries will be convinced that such gifts as that of Sir Thomas Muir are not likely to be wasted.

THE meeting of the Physical Society of London on March 26 took the form of a discussion on Einstein's theory of relativity. Prof. A. S. Eddington opened with an explanatory lecture. Prof. A. O. Rankine described experiments undertaken in collaboration with Dr. Silberstein on the influence of a gravitational field on the velocity of light polarised in a plane parallel to the field; the results of the experiment were in accord with the theory. Sir Joseph Larmor contributed a paper in the course of which he remarked that "the unresolvable essence of relativity appears to be that we cannot get on without *some foundation* to which phenomena are referred, and with respect to which they are ordered to the degree that is necessary for our reasonings." Reference was made also to the close relation between the theory and the fundamental principle of least action. That principle furnishes the most concise and elegant means of comprehending Einstein's theory. Here Helmholtz was a pioneer, not only in his grasp of physical principles, but also in his appreciation of the true nature of geometry. The searching question was asked: "How is it that astronomers since Newton's time have persisted in one special and very precise illusion about the distribution of gravitation, whereas really an unlimited choice is open?" Several speakers raised questions about the interpretation of the Michelson-Morley experiment, indicating that the explanations offered both by Lorentz and by Einstein still remain unconvincing to many physicists.

THERE are many chemists, and doubtless other scientific workers, who, busy with their everyday duties, have not been able to follow closely the progress made during the last few years in the study of atomic structure, and would welcome a connected survey of recent experiments and present views. Hence attention may be directed to an address by Prof. A. Berthoud on "The Structure of Atoms," a translation of which appears in the *Chemical News* of April 9 and 16. This gives, in simple language, a very readable account of the matter. It shows the connections which have been traced between the phenomena of radio-activity, isotopy, atomic numbers, Moseley's law, Bohr's theory, and the spectra of the elements; and it indicates to what extent the fundamental characters of atomic structure may now be regarded as known, however much of detail may still be waiting for the sagacity of the investigator to fill in.

MESSRS. ILFORD, LTD., in issuing a second edition of their well-known booklet on "Panchromatism," have taken the opportunity of revising it and making some important additions. The largest of the new sections explains the nature of three-colour photography, in which is demonstrated the fact that in three-colour half-tone prints, granting the use of satisfactory inks, the result is the same whether the dots are side by side or superposed. The variability of so-called "white light" is treated of, the table of the multiplying factors of colour-filters is greatly extended, and a considerable number of new filters are described. The most novel and interesting of these last are the "photographic-vision" filters, which have transmissions that correspond with the sensitiveness of an orthochromatic or panchromatic plate, and therefore, when looked through, give the object or landscape the appearance that it will have when photographed on the plate that it matches. The effect of any colour-filter on the photograph is seen at once by putting the filter together with the "photographic-vision" filter in front of the eye. The price of the booklet is 6*d*., or post free 9*d*.

MESSRS. A. GALLENKAMP AND CO., LTD., have forwarded us a copy of their list (No. 72) of graduated instruments for volumetric analysis. These include burettes, pipettes, graduated cylinders, and various kinds of measuring flasks for use in the chemical and physical laboratory; we do not, however, notice pyknometers in the list. The instruments are made in three qualities, depending upon the degree of accuracy required. Those intended for research and special work (Grade A) are graduated according to the regulations laid down by the International Congress of 1909. Apparatus of the next quality (Grade B) is intended for specially accurate commercial analysis; and that in Grade C is suitable for ordinary technical determinations and general schoolwork. It is satisfactory to know that our makers of scientific glassware are endeavouring to meet the requirements of all users, including those of research workers. Whilst writing on this subject we may note that, from a report appearing in the Journal of the Society of Glass Technologists (December, 1919), there is a movement in Germany to restrict and standardise the shapes and sizes of glass vessels such as beakers, flasks, retorts, cylinders, and crystallising dishes in order to eliminate unnecessary diversity and facilitate replacement. The proposed standard dimensions are quoted at length.

MESSRS. H. K. LEWIS AND CO., LTD., 136 Gower Street, W.C.1, have just issued a list (dated April) of new books and new editions added to their medical and scientific circulating library during January, February, and March of the present year. Being very comprehensive and carefully classified, it should be useful to all who wish to keep abreast of current scientific literature. Copies can be obtained free of charge upon application to the publishers.

Our Astronomical Column.

THE LUNAR ECLIPSE.—On the whole this eclipse was seen under favourable weather conditions, though for a time there was drifting cloud. The eclipsed portion was easily visible, being at first of a greenish tint, and later assuming the familiar coppery hue. Mr. A. Burnet had prepared a list of stars occulted during totality; they were few, and faint, and only one of these phenomena was observed at Greenwich. There will not be another total lunar eclipse visible in London with the moon at a considerable altitude until November 7, 1938, which is a much longer interval than usual.

THE NATURE OF PHOTOGRAPHIC IMAGES.—Dr. Kenneth Mees, director of the Research Institute of the Eastman Kodak Co., New York, gave an address at the meeting of the British Astronomical Association on April 28 on the nature of photographic images. Various points were raised that are of importance in the application of photography to astrophysics. Thus in the extra-focal determination of stellar magnitudes it was demonstrated that stars of different colours might have their magnitudes arranged in a different order, according to the exposures given and the developer employed.

Magnified sections of films were thrown on the screen, showing that with some developers the image of a luminous object caused an elevation of the film, but with other developers a depression. In either case the film in the neighbourhood suffers strain (sometimes to the point of cracking), so that images of faint stars near a bright one are subject to displacement. Prof. Turner noted some time ago an apparent displacement of a star near a *réseau* line which was probably due to this cause. It is possible to minimise the effect by a judicious choice of developer. The address contained many other hints of a practical nature; it will be published in the B.A.A. Journal for April. The Astronomer-Royal, proposing a vote of thanks, said that photography was the only way of obtaining information about the fainter stars in bulk. While some of the phenomena described by the lecturer were a little disquieting, the careful analysis of their origin and effects could not fail to be of great value.

THE BINARY KRUEGER 60.—This system is of particular interest as being one of our nearest neighbours, and since the *comes* has the smallest mass yet found for any star. *Astronomical Journal*, No. 767, contains researches on the parallax, proper motion, and orbit made at the Leander McCormick Observatory by S. A. Mitchell and C. P. Olivier. They find for the relative parallax $0.266'' \pm 0.009''$. Combining this with the determinations of Barnard, Schlesinger, and Russell, and adding $0.005''$ as the estimated value for the comparison stars, the absolute value $0.261'' \pm 0.006''$ results.

Their orbit makes the period nearly fifty years, a being $2.68''$, or 10 astronomical units. Hence the combined mass is 0.42 in terms of the sun. The ratio of masses of the two components is still uncertain; three estimates are 0.35, 0.53, and 0.83. Taking it as 0.5, the faint component is 1/7th of the sun in mass, while it is only 1/2500th of it in luminosity. Prof. Eddington considered that the minimum mass necessary for the attainment of a stellar state may not be much below 1/7th of the sun.

It is pointed out that the photographs of the close pair give as good results as visual measures, while for the distant optical component, observed for the purpose of deducing the relative masses, they are more accurate. Comparisons continued for another twenty-five years should give a satisfactory determination both of the orbit and the mass-ratio.

Leonardo da Vinci.[1]

By EDWARD MCCURDY.

AMONG the greater names in the history of Italian art some are found to be pivotal by reason of the influence of their work upon that of other artists. Giotto and Masaccio are the most conspicuous instances among the earlier masters. Giotto created the scientific basis of the naturalism of the art of the Renaissance by contrast with the decorative symbolism of the earlier art of Byzantium. Masaccio reinforced these tenets with noteworthy access of realism in the frescoes in the Church of the Carmine in Florence. The names of Antonio Pollaiuolo and Andrea Verrocchio serve to indicate how in Florentine art of the Quattrocento the study of structure gained new scientific precision from anatomical research. Piero de' Franceschi reveals a deeper knowledge of the various problems of perspective, arrangement, and light and shade in his works at Arezzo than was possessed by any of his contemporaries, but the influence which his work would naturally exert was restricted by reason of its remoteness from the greater centres of art training.

The divergent aims of this small band, who may be termed the upholders of the scientific tradition in Italian art, are realised with singular completeness in the work of Leonardo da Vinci. Born in the year 1452, the illegitimate son of a Florentine notary, descended from a long line of Florentine notaries, having shown, according to Vasari, marvellous talent as a boy in the art of design, he was placed by his father in the studio of Andrea Verrocchio, who is described by the same writer as at once goldsmith, master of perspective, sculptor, inlayer of woods, painter, and musician. It was apparently a sort of clearing-house for ideas for the art world of Florence, and there Leonardo became acquainted with Botticelli and Perugino. His apprenticeship had ceased in 1472, for in that year his name occurs in the Red Book of the Guild of Painters of Florence.

In the year 1483 Leonardo, being then in his thirty-second year, left Florence and went to Milan, where he entered the service of Ludovic Sforza. Making all possible allowance for what may have been lost, the sum total of his work in art up to this time is astonishingly small as covering the period from his apprenticeship to his thirty-second year. Already in his few pictures the detailed treatment of the herbage, the gradation of the light, the presentment of muscle and tendon, all reveal the scientific study of the laws which defined their structure. The inference is irresistible that while still at Florence he had commenced those studies of natural and applied science the rumour of which, superimposed upon the fame of his artistic work, caused his name to be endowed among his contemporaries with a half-legendary universality. Some of the forms of this nascent activity are enumerated by Vasari. I quote from the translation by Mr. Herbert Horne:—

"In architecture he made many drawings, both of plans as of other projections of buildings; and he was the first, although a mere youth, that put forward the project of reducing the River Arno to a navigable channel from Pisa to Florence. He made designs for flour-mills, fulling-mills, and machines which might be driven by the force of water. . . .

"And he was for ever making models and designs to enable men to remove mountains with facility, and to bore them in order to pass from one level to another; and by means of levers, and cranes, and screws he showed how great weights could be lifted and drawn; together with methods of emptying

[1] From a discourse delivered at the Royal Institution on Friday, March 19.

harbours and pumps for drawing up water from low places, all which his brain never ceased from inventing."

In the famous draft of a letter to Ludovic Sforza, in the Codice Atlantico, written presumably immediately on his arrival in Milan, Leonardo offers his services in the capacity of military or naval engineer, detailing the various inventions of which he possesses the secret, and offering to make trial of any, either in the ducal park or in whatsoever place might please his Excellency, in case any of the said inventions should seem to be impossible. If natural incredulity, which the writer of the letter apparently expected to meet with, by reason of the scope and variety of the inventions, which comprise pontoons, scaling-ladders, cannon or bombards, mines, covered chariots, catapults, mangonels, and smoke-powders, should dispose any to look on the list merely as a piece of rodomontade, it may be observed that the contents of Leonardo's manuscripts at Paris and Milan fully substantiate every claim contained in the letter.

The position which Leonardo desired to occupy under Ludovic Sforza was not very unlike that of military engineer and inspector of fortresses which he occupied at a later period in the service of Cæsar Borgia.

The concluding paragraphs of the letter to Ludovic Sforza refer to Leonardo's readiness to be employed in the arts of peace—in architecture as a designer of both public and private buildings, in the construction of watercourses, in painting, and in sculpture, whether of marble, bronze, or clay, and especially in the execution of the equestrian statue of Francesco Sforza, upon which he laboured intermittently for sixteen years. The extent and fervency of the researches that he considered necessary, which comprised studies of various antique equestrian statues, and numerous notes on the proportions of particular horses, as well as a treatise on the anatomy of the horse, were such that the very desire of perfection prevented the execution of the work. As Vasari says, quoting Petrarch's line: "L'opera fosse ritardata dal desio." The monk, Sabba da Castiglione, who was present when the French entered Milan in 1499, records the fact of the destruction of the clay model under the arrows of the Gascon bowmen. The statue ranked with Donatello's Gattamelata at Padua and Verrocchio's Bartolommeo Colleone at Venice as one of the three great examples of equestrian statues of the Italian Renaissance. So far as it is possible to form an opinion from the very numerous studies in the Royal Collection at Windsor, it would seem to have been in advance of both the others in freedom and vigour of movement. The sequence of studies shows a change of purpose from the attitude of the horse galloping to that of it walking. Leonardo says in a note in one of his manuscripts, "The trot is almost the nature of the free horse."

Few paintings are now in existence the execution of which can be connected with Leonardo's first period of residence in Milan. The most important of these is the haunting ruin of the Last Supper. The paucity of the list, even allowing for the inevitable mischances of time, confirms the testimony of Sabba da Castiglione, who says that, besides the Last Supper, few other works in painting by Leonardo were to be seen at Milan in the middle of the sixteenth century, "because when he ought to have attended to painting, in which without doubt he would have proved a new Apelles, he gave himself entirely to geometry, architecture, and anatomy."

The external history of his life is sharply divided by circumstances into three periods. First the early years at Florence. Then his life at Milan under Ludovic Sforza. The third period was that of the Odyssey of wanderings commenced on his leaving Milan with Fra Luca Paciolo two months after the flight of Ludovic Sforza, and extended for the remaining twenty years of his life.

At Venice, as Leonardo's manuscripts show, he studied the tides of the Adriatic, and apparently prepared a scheme for flooding part of the Veneto in order to stem the Turkish invasion, and also an apparatus by which it would be possible to approach the Turkish galleys under water. A note in the Codice Atlantico tells of his hurried departure from Florence to travel in the Romagna as architect and military engineer in the service of Cæsar Borgia. His manuscripts refer to works planned at Urbino, Cesena, and Porto Cesenatico. But the office ended with the rebellion of the Duchy, and in March, 1503, Leonardo was once more back in Florence. There he was employed to divert the channel of the Arno, in connection with the war with Pisa. He painted at this time the portrait of Madonna Lisa del Giocondo, the world-famous Mona Lisa, and also the cartoon for the Battle of Anghiari. His work on this composition was interrupted by an invitation to Milan, and this led to his entering the service of the French. Louis XII. refers to him in a letter to the Signoria as "our painter and engineer in ordinary." He consulted him as to the conduit in the garden of the Château of Blois, and employed him on hydraulic work in Lombardy. It was probably in May, 1509, when Louis XII. made a triumphal entry into Milan after the victory of Agnadello, that Leonardo constructed as part of the pageant an automatic lion which walked a few paces and then, opening its breast, revealed it full of lilies. There was much study of anatomy with Marc Antonio della Torre at this period, and his intercourse with French artists is shown by a note to inquire from Jean de Paris the method of painting in tempera, but he did not engage in any great artistic work.

In the year 1512 the French lost Milan, and after the re-entry of the Sforzas, in the person of the young Maximilian, there is no record of Leonardo's further employment. On September 24 in the following year he set out from Milan to Rome with his assistants, and was there lodged in the Belvedere of the Vatican. According to Vasari, the Pope gave him a commission, and then was indignant because he began by experimenting with the varnish. The practice of painting, however, had no more than a secondary interest for him. His manuscripts reveal him as engaged in studies in optics, acoustics, and geometry, studying geology in the Campagna, improving the method of coining at the Mint at Rome, busy with engineering work at Cività Vecchia, and in studying anatomy at the hospital, for which last-named pursuit he was denounced to the Pope by one of his apprentices. He seems to have gone with the Papal army to Bologna, where in December, 1515, the Concordat was held between the Pope and Francis I., and a month later he accompanied the king on his return to France with the office of "his painter and engineer," being given as a residence the Château of Cloux, near Amboise, where he died on May 2, 151[illegible]

A record of a visit paid to him at Cloux by the Cardinal of Aragon on October 10, 1517, makes special mention of the anatomical drawings, and the diarist states that Leonardo told the visitors that in preparation for these he had dissected more than thirty bodies. They saw also his treatise on the nature of water, and others on various machines, there being, as it appeared, "an endless number of volumes, all in the vulgar tongue, which if they be published will be profitable and very delectable."

The activities of Leonardo's mind fall naturally into

such as found expression, either mainly or in part, in constructive work and those revealed only in his writings. The first category comprises painting, sculpture, architecture, and engineering. In painting it is enough to instance the fresco of the Last Supper and the portrait of Mona Lisa, each of its type unique among all works of the Renaissance, and beyond all power to appraise in its union of technical mastery and the inevitability of supreme art. In sculpture the Sforza statue, the master-work of his Milanese years, lives only in the drawings which furnish some faint index of its power. In architecture there is no outstanding memorial.

Sir Theodore Cook, in his elaborate study of spiral forms entitled "The Curves of Life," has collected a remarkable array of evidence in favour of attributing to Leonardo the design for the open spiral staircase in the Château of Blois. The documentary evidence is missing, but the date of construction is known to have been between the years 1516 and 1519, and Leonardo was then living a few miles distant in the manor-house of Cloux, near Amboise. A spiral staircase occurs in one of Leonardo's drawings for a fortified tower, and he made many studies of spiral formations occurring in Nature, in shells, in smoke, and in the eddies of water. The staircase at Blois is apparently modelled on *Voluta vespertilio*, a shell common on the coast of northern Italy. The theory has obvious attractions. It supplies an example of a work in architecture emanating from the brain of Leonardo, and this a work of supreme distinction.

Records of his activity as an engineer are concerned with schemes of canalisation in Florence, in connection with the diversion of the Arno from Pisa as a war measure; and in Friuli, in similar circumstances, he devised movable sluices in order to prevent the advance of the Turks across the Isonzo. He made canals in Lombardy for purposes of irrigation, and also aqueducts to improve the water-supply of Milan; and the canal of Romorantin, for which he made plans when in France, was intended to connect the waters of the Loire and the Saône.

The potential list of Leonardo's activities in the construction of instruments of warfare figures in the letter to Ludovic Sforza. He says there: "I can make armoured wagons safe and immune from attack which will open up a passage through the enemy with their artillery, and, however great the multitude of the enemy may be, they will be able to break through. And behind them the infantry will be able to follow quite unhurt and without hindrance."

This armoured wagon is seen ready for action in a drawing in the British Museum. It is moved on wheels, and a sketch of the lower half shows the internal machinery, but it is not possible to discern the nature of the motive power. The use of the armoured wagon in order to open up a passage through the enemy, as described above, is identical with that of the tank in the late war. The manuscripts reveal a strangely prophetic insight in regard to two other developments of recent warfare, namely, poison gas and submarining.

Leonardo contemplated the use of poisonous gas or powders in naval warfare for the purpose of suffocating the enemy, and told how to make a simple preventive mask. He also contemplated the contingency—as happened on occasions in Flanders—of an adverse wind causing the poison to recoil upon the users. The passage, which occurs in MS. B of the Paris manuscripts, is entitled "How to throw poison in the form of powder upon ships."

"By means of catapults," he says, "a mixture of powdered quicklime, arsenic, and verdigris may be thrown upon the ships of the enemy, and all who inhale the powder will die.

"But take care that the wind is favourable, lest it blow the powder back upon you, and be sure you have a fine piece of damp cloth to cover the nose and mouth in order that the powder may not enter."

In the Leicester manuscript (folio 22*b*) he foretells the horrors of submarine warfare, and refuses to impart any information as to the machine which he has constructed lest it should serve to bring them about:

"How by means of a certain machine many people may stay some time under water. How and why I do not describe my method of remaining under water, or how long I can remain without eating; and I do not publish or divulge this because of the evil nature of men who would use them as means of destruction at the bottom of the sea by smashing the ships in the keel and sinking them together with the men in them. But I will impart others which are not dangerous, because the mouth of the tube by which you breathe appears above the water supported on leather bottles or corks."

In connection with this passage reference may be made to one in MS. B of the Paris manuscripts entitled "A Way of Escaping in a Tempest or Shipwreck at Sea," in which Leonardo tells how to construct a coat of leather of double thickness which will be capable of being inflated when necessary, and thus of serving as a life-saving jacket in case of emergency.

Senatore Luca Beltrami associates the former of these passages with the Turkish war. Leonardo, as a reference to his manuscript shows, had been employed in the construction of a movable dam which should enable the line of the Isonzo to be flooded in the defence of the Veneto against the Turkish invasion. The reference is to the construction of submarine boats in order to sink the Turkish galleys in the Gulf of Venice "by smashing the ships in the keel and sinking them together with the men in them." Leonardo considers this to be justifiable, because it is an act of defence "for the safety of our Italian lands" ("delli nostre parti italiche"); but he will not give any details of the construction of his submarine craft in which it would be possible to remain under water for four hours, because he is fearful of the evil use to which it might be put in future times.

(*To be continued.*)

Public Support of Scientific Research.

ON Wednesday, April 28, a public meeting was held at Birkbeck College to hear an address from Prof. F. Soddy on "The Public Support of Scientific Research." Mr. H. G. Wells, who took the chair, claimed that everything in which the world of to-day differed from that of years ago was due to science and the scientific worker. Prof. Soddy expressed his regret that the greater encouragement of scientific research during the war had not resulted in any appreciable improvement in the position of pure science, which was the tree of which applied—industrial and trade—science were the fruits. He deprecated the exploitation of science by financiers and commercial men and its employment to increase the indebtedness to them of those who had done the creative work of the world. The scheme framed by the Government to foster scientific research endeavoured to place the man of science who was to do the work under the same type of men—often the same men—as had thwarted progress in the past. The change from gross inefficiency in the medical

services in the Boer War to singular efficiency in the late war was due to change in the status of the Army medical officers and to their liberation from the misdirection of unqualified superiors. This was possible only because of the great strength of the professional union of medical men. A similar strong professional union comprising every qualified man of science was necessary before science ceased to be misdirected and used to the hurt rather than to the good of the community.

Not a single chemist was included in the directorate of the national scheme for the manufacture of British dyes when it was announced, although the taxpayer contributed 2,000,000*l.*, a portion of which was to be expended in research. The cause of the success of the German industry was that it was under scientific direction from end to end. Prof. Soddy complained that the benefaction of Mr. Carnegie to foster scientific study and research at the Scottish universities had been diverted to the general maintenance of the universities. At one time none of the trustees were men of science, and the secretary was now the administrative chairman of the Government Department of Scientific and Industrial Research. That Department allocated a million to industrial research associations in the form of a capital grant, over which Parliament was powerless, whereas researches in the fields of pure science, from which directly flowed all the useful applications, were put on the yearly Parliamentary Estimates. The research associations were becoming water-tight concerns to eliminate competitors, and the interests neither of the public nor of the scientific worker were protected. Representatives both of trained scientific workers and of organised labour should be included in the councils and executive committees of the research associations. At the same time, Prof. Soddy urged that representatives of democratically constituted associations of scientific workers should be placed on the Council of the Department, of which it should be the governing body. He declared his belief that co-operation would replace competition; but this co-operation depended upon a dominance of individuals of intellect and knowledge—not over men, but over Nature; for the struggle of man against Nature was, in the first instance, a duel fought by lonely men in the furthest outposts of knowledge, finding a path where all before had turned back beaten and befogged.

In the discussion which followed Sir William Bragg urged that as science slowly established its position and men of science reached a condition of greater equity, responsibility came with it, and they must work and learn to handle greater and greater things, so that they might take their part in everything that was done in the State. He expressed his appreciation of the assistance he had received from the Department of Scientific and Industrial Research.

American Agricultural Research.

RECENT numbers of the *Journal of Agricultural Research* (vol. xviii., Nos. 7 and 8) contain several articles dealing with plant physiology and with insect pests. Plants grown in water-culture are not able to withstand such high concentrations of nutrient salts without showing toxic effects as are plants grown in sand or soil. In the latter case the presence of solid particles, which cause a considerable amount of absorption, has much to do with this reduction of toxicity, but J. A. Le Clerc and J. F. Breazeale have shown that the effect is also partly due to certain soluble substances which are sometimes present in very small quantities. Traces of calcium oxide and calcium sulphate do much to overcome the toxicity of sodium chloride and sodium sulphate, but the various other salts tested had no ameliorating action. The lime, however, does not seem to prevent the entrance of the sodium chloride or sulphate into the plant-cells, and therefore its antagonistic action would appear to be due to some undetermined cause rather than to its effect upon the permeability of the cells.

The question of the physiological balance of the salts necessary for plant nutrition is many-sided, and J. W. Shive approaches it from the point of view of the relation of the moisture in solid substrata to the physiological salt-balance and to the relative plant-producing value of various salt proportions. Under his experimental conditions the physiological value of salt solutions was not affected by the degree of moisture present, and that which was best with the lowest moisture-content was also the best with the medium and the highest degrees of moisture. Nevertheless, an optimum moisture-content is necessary to produce maximum growth, and the actual plant-producing value of any fertiliser treatment is largely determined by the moisture conditions of the substratum.

It is customary to subject cereal seeds to treatment by hot water or various chemicals in order to control plant diseases when their presence on the seed is known or suspected. Such treatments are not effective in every case, as measures that are sufficiently drastic to cut out the disease often result in destroying the viability of the seed. D. Atanasoff and A. G. Johnson find that these difficulties may be largely overcome by the use of dry heat for disinfection, as such cereals as barley, wheat, rye, and oats are able to withstand protracted exposures to dry heat at comparatively high temperatures, especially if the seed is of good quality and well dried. The method has proved successful in the elimination of seed infection from bacterial blight of barley (*Bacterium translucens*) and bacterial blight of oats (*Pseudonomas avenae*), and a number of seed-borne fungus diseases, such as wheat-scab, spot-blotch of barley, stripe disease, and smut, are either practically eliminated or much reduced. The dry heat treatment seems to offer possibilities which should be followed up.

Natural enemies must be regarded as a great asset in the control of insect pests, but the value of fungal parasites in this respect is often overlooked. A. T. Speare describes experiments on *Sorosporella uvella*, an entomogenous fungus which attacks Noctuid larvæ, and is recorded for the first time in America. The practical interest of the investigation lies in the fact that quite a number of Noctuid larvæ, including such pests as cutworms, have proved to be susceptible to the disease, and other Lepidopterous larvæ can also be infected by special methods. The disease caused by the organism is readily transmitted to healthy insects, and in laboratory experiments a mortality of from 60 to 90 per cent. may be obtained. Control by means of parasitism has proved of great value in reducing the Mediterranean fruit-fly in Hawaii. Four larval parasites of this pest have been introduced and established since 1913, and their value as destroyers increased until in 1918 they caused the destruction of considerably more than half of all the fruit-flies developing in fruits about Honolulu (H. F. Willard).

The ravages of the broad-bean weevil (*Bruchus rufimanus*, Boh) in California have led to the abandonment of a considerable acreage, especially since weevil-infested beans have been classed as adulterated food. R. E. Campbell (Bull. 807, Professional Paper, U.S.A. Dept. Agric.) gives an account of the distribution and life-history of the pest and discusses various measures of control. The only practicable means is to plant seed which contains no live weevils,

as the application of poisons or deterrents in the field is useless. Dry heat is unsatisfactory, as temperatures that destroy the weevils kill the seeds also; sulphur is unsuccessful, but fumigation of well-matured and dry seeds with carbon bisulphide gives good results. Damp seeds should not be treated. Contrary to expectation, it was found that fumigating while the insects were in the larval stage was less effective than if done in the adult stage, as the gas cannot penetrate into the interior of the bean to the partly grown larvæ as easily as it can reach the full-grown larvæ, pupæ, or adults directly under the seed-coat.

W. E. B.

Canadian Water-Power Development.

AN interesting article in the *Engineer* of April 9 by Mr. Leo. G. Dennis, Hydro-electric Engineer of the Canadian Commission of Conservation, reviews the situation in regard to Canadian water-power development. From it we have gathered the following particulars indicating the remarkable growth since the commencement of the century.

In 1900 less than 200,000 h.p. was utilised, as compared with 2,383,240 h.p. now available, according to the most recent returns, subdivided as follows:—

Province.	Horse power
Ontario	1,000,000
Quebec	900,000
British Columbia	310,000
Manitoba	78,600
Alberta	32,500
Nova Scotia	30,000
New Brunswick	17,000
Yukon	13,400
Prince Edward Island	1,700
Saskatchewan	40

Of the total electric central station installation of 2,107,743 h.p., no less than 1,806,618 h.p., or more than 85 per cent., is in hydro-electric stations, and these are remarkable for their large size. Forty per cent is in plants of 100,000 h.p. and more, and another 42 per cent. in plants between 10,000 and 100,000 h.p. Particularly worthy of note are two large hydro-electric systems in Eastern Canada. The Niagara system is supplied mainly from plant of 211,300 h.p., and transmits to some 150 municipal distribution centres. The Shawinigan system is fed from plants with a total capacity of 270,000 h.p., and, directly or indirectly, supplies some 85 distributing systems.

Water-power is an important factor in many Canadian industries, but in none so essentially as in the case of pulp and paper manufacture. Of a total of 525,000 h.p. installed for this purpose, at least 475,000 h.p. is derived from hydraulic sources. From an economic point of view it is probable that if water-power had not been available, pulp in many cases could not be manufactured at all.

Canada's potential water-power resources are placed by recent estimates at 18,832,000 h.p., subdivided provincially as follows:

Province.	Horse-power.
Quebec	6,000,000
Ontario	5,800,000
British Columbia	3,000,000
Manitoba	2,797,000
Alberta	462,000
New Brunswick	300,000
Saskatchewan	220,000
Nova Scotia	100,000
Yukon	100,000
North-West Territories	50,000
Prince Edward Island	3,000

In Ontario, the Niagara and St. Lawrence powers are the outstanding features, although the figures in regard to the former have been at times exaggerated. Bearing in mind that it is an international source, the theoretical total available for Canada is about 2,300,000 h.p. But only about one-third of that quantity is at present available for exploitation. The large power plants installed below the Falls have not so far utilised the descent in the river below the cataract, but this mistake is not being repeated by the Chippawa-Queenston project, which will add 200,000 h.p. to the total installation. It will embrace the maximum possible head of 316 ft. The St. Lawrence powers are also partly international, and are estimated as follows:

Province or State.	Available low-water horse-power.
Ontario	387,500
New York	387,500
Quebec	1,375,000
	2,150,000

Besides its share of the St Lawrence and Ottawa River powers, Quebec has other important possibilities, notably on the St. Maurice River and in the Sagaway basin. The present capacity of plants at Shawinigan and Grand'mère in the Upper St. Maurice is 330,000 h.p., and there is expectation of this figure being doubled at no distant date.

The Solar Eclipse of May, 1919.

PROF. L. A. BAUER contributes an article on this eclipse to a recent issue of *Science*. He notes the new interest which eclipses have recently acquired, first from their effect on terrestrial magnetism, and secondly from the gravitational deflection of light. The Carnegie Institution of Washington sent two parties to stations inside the zone of totality; Prof. Bauer himself occupied Cape Palmas, Liberia, while Messrs. Wise and Thomson went to Sobral, Brazil. There were three other stations outside the zone, and most of the magnetic observatories co-operated in a scheme of observations. The detailed results are not yet available.

Cape Palmas has a bad weather record, but this was of little importance for the magnetic work. The sun was very high, and the duration of totality, 6m. 33s., was probably the longest that a scientific party has ever enjoyed. As it turned out, the sky was clear, and small-scale photographs of the corona were secured. These were, however, subsidiary to the main work, of which Prof. Bauer says: "There were clear indications of a magnetic effect. . . . As the station was nearly on the magnetic equator, the effect was specially noticeable . . . upon the magnetic dip." He notes that the darkness was not nearly so great as at the much shorter eclipse of 1918, perhaps owing to the greater brightness of the corona. The fall of temperature was nearly 3° F., the minimum being some twenty-four minutes after totality; the maximum of humidity synchronised with this minimum. Shadow bands were not seen here, but they were observed at Sobral by Mr. Thomson.

Dr. Abbot and Mr. Moore observed the eclipse from La Paz, Bolivia, where the sun's altitude was only 5°, but their altitude of 14,000 ft. compensated for this. "Taking into account the great length and beauty of the coronal streamers, the splendid crimson prominence . . . the snow-covered mountains as a background, it seemed to the observers the grandest eclipse that they had seen." Besides photographing the corona, their special work was the measurement

of sky and solar radiation at different stages of the eclipse. Curves of these are given, which indicate that the sky radiation varies proportionally to the amount of sunlight.

Prof. Bauer then discusses the British expeditions and the observed deflection of light. As these have already been dealt with in NATURE (November 13, 1919, and elsewhere), it will suffice to mention one point. After noting that the Sobral results indicated larger deflection than those deduced from Einstein's law, and that the excess was greater in R.A. than in declination, Prof. Bauer made the suggestion that the excess might arise from the passage of the light through a rare outer atmosphere of the sun, which, like the corona, might be more extended in the equatorial regions. The residuals are too small to lay very much stress on this, unless future eclipses should indicate the same effect.

The Manufacture of Synthetic Ammonia and Production of Nitrates.

THE Ministry of Munitions announces that Lord Inverforth has arranged for the sale of H.M. Nitrate Factory at Billingham-on-Tees to Messrs. Brunner, Mond, and Co., Ltd. The purchasers will form a company to take over the factory, and will be responsible for all outstanding liabilities of the Ministry in connection with the project. This factory, the erection of which was commenced early in 1918 by the Department of Explosives Supply, was designed for the manufacture of synthetic ammonia and for the production of 60,000 to 70,000 tons of ammonium nitrate annually.

Soon after the appointment of the Nitrogen Products Committee, the monumental report of which was published in January last, the Government decided to install one or other of the processes for the fixation of nitrogen. The Committee, after thorough investigation of the problem, recommended the cyanamide process as the one best suited for this purpose in the circumstances, since the working details were well understood. This advice was at first adopted, and a contract was on the point of being negotiated, but, for reasons which are not stated, the recommendation was not acted upon.

During 1916 the Nitrogen Products Committee had established a laboratory in premises placed at its disposal in the new Ramsay building of University College, London, and the Committee's research staff, under the direction of Dr. J. A. Harker, was engaged in an experimental investigation of a number of problems relating to nitrogen fixation. Although it was not anticipated that there would be any shortage of supplies of ammonia, yet it was deemed desirable, in view of the special suitability of the synthetic ammonia process for the needs of this country, that an experimental study of it should be made forthwith, so that the required information should be available if necessary.

After a year's experimental work, the progress made was considered so encouraging that the Committee decided to establish a moderate-sized technical trial unit, and funds for the purpose were allocated by the Treasury. It was hoped, by means of this plant, that a study of the chemical engineering problems could follow upon that already made of the pure chemistry of the reactions involved, but the Committee did not suggest the establishment of the process as a war measure upon an industrial scale. In 1917, however, the Explosives Supply Department considered that the position reached in the experiments justified it in recommending the erection of a large works, in substitution for the Committee's cyanamide project, and a site at Billingham, some 260 acres in extent, was ultimately chosen for this purpose. But a number of difficulties supervened, and construction was slow, and at the time of the Armistice only a few permanent buildings and a number of temporary structures had been erected, though a large amount of plant had been ordered.

The purchasers of the factory now undertake to complete the scheme by providing the additional buildings and plant required for the synthesis of ammonia and its oxidation to nitric acid and nitrates suitable for the manufacture of explosives and fertilisers.

It is understood that the company has acquired a large amount of additional land and that it intends to develop the project on a very large scale. The factory has been re-designed on a peace as distinct from its former war basis, and in many particulars the new plant will represent a substantial advance, both in the ammonia and nitric acid sections, on anything previously used in Germany.

New Ordnance Survey Maps.

THE new edition of the one-inch and quarter-inch Ordnance Survey maps is described, with specimen sheets, by Lt.-Col. W. J. Johnston in the *Geographical Journal* for March (vol. lv., No. 3). Three types of one-inch map are to be published: the popular, the district tourist, and the outline. The popular edition has contours in orange at 50-ft. vertical interval in place of the 100-ft. and 250-ft. interval on the former one-inch maps. A new classification of roads, which divides them into ten categories, makes the main roads, coloured red, stand out prominently. Rivers and streams are shown in solid blue. Parish boundaries, which caused much confusion with footpaths, are omitted, but county boundaries are retained. Woods are coloured green. The outline edition is the present one-inch map, which in future will be printed from stone on stout paper. The tourist edition entails a combination of sheets to cover conveniently in one map certain areas frequented by holiday-makers. It is hoped to have at least eight of the tourist sheets ready before the summer. The contours are at 100-ft. and 250-ft. intervals, and the representation of relief is made more striking by the use of hachures and transparent colour layers; rivers are in solid blue and woods in green. The black printing will be the same as in the popular edition. The quarter-inch map is being issued with contours and layer colours in place of hill shading, red colour for main roads only, solid blue for streams, and no green wood symbol. The sample sections of the popular one-inch and the quarter-inch maps accompanying Col. Johnston's paper are beautiful specimens of cartography, and a great improvement on the old editions, good as they were. The tourist one-inch will be useful mainly by reason of the combination of sheets which it offers. We understand that arrangements have been made to popularise these maps by having them on sale at all booksellers' and bookstalls.

University and Educational Intelligence.

CAMBRIDGE.—Gifts totalling 1500*l*. are announced towards the partially endowed Hopkinson professorship in thermodynamics.

The Linacre lecture will be delivered to-day, May 6, by Dr. Henry Head on "Aphasia and Kindred Disorders of the Speech."

In connection with the installation of the Chancellor, it is proposed to present honorary degrees to the Prime Minister, Mr. Bonar Law, and several other prominent politicians. The following are amongst those selected for honorary degrees on the same occasion: Sir Joseph

Thomson, Sir Joseph Larmor, Sir J. G. Frazer, Prof. James Ward, Mr. C. M. Doughty, and Prof. Bergson.

The Sheepshanks exhibition in astronomy has been awarded to E. S. Pearson, scholar of Trinity College.

The first examination for the diploma in medical radiology and electrology will be held on July 27 next.

Mr. H. Hamshaw-Thomas has been re-appointed curator of the Botanical Museum.

LONDON.—A course of eight lectures on "Nutrition," by Prof. E. Mellanby, at King's College for Women, Campden Hill Road, Kensington, W.8, was begun on Monday, May 3, and will be continued at 5 p.m. on Mondays and Tuesdays, May 10, 11, 17, 18, and 31 and June 1. Another course of eight lectures on "The Biochemistry of Sterols" will be given by Mr. J. A. Gardner in the Physiological Laboratory of the University, South Kensington, S.W.7, at 5 p.m., on Tuesdays, May 18 and 25, June 1, 8, 15, 22, and 29, and July 6. The lectures are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket.

At University College, on Wednesday next, May 12, at 5.30, Dr. Charles Singer will deliver a public inaugural lecture, as lecturer in the history of medicine, on "Greek Science and Modern Science: A Comparison and a Contrast." The chair will be taken by Sir Robert Hadfield, Bart.

OXFORD.—On May 4 Convocation passed a decree gratefully accepting the offer of Mr. Edward Whitley, of Trinity College, of a sum of 10,000*l*. towards the endowment of a professorship of biochemistry, and providing that the first appointment of a professor shall be made by Mr. Whitley, subject to the approval of the Vice-Chancellor and the professors of medicine, physiology, chemistry, and pharmacology.

By another decree Convocation expressed its thanks to the British Dyestuffs Corporation for its munificent donation of 5000*l*. towards the cost of extending the organic chemical laboratory.

These gifts to the University are most timely and welcome. The opportunity thus afforded for the study of the important subject of biochemistry in the University is likely to have far-reaching results; while increased accommodation for the department of organic chemistry has for some time past been urgently needed.

THE chairman and directors of the Cunard Steamship Company have decided to contribute 10,000*l*. to the appeal fund of the University of Liverpool.

THE HON. SIR CHARLES A. SMITH, for many years Controller and Auditor-General of Cape Colony, who died a year ago, bequeathed 15,000*l*. to the Master and Fellows of St. Peter's (Peterhouse) College, Cambridge, "for the advancement of education and learning, the fund to be associated with his name."

WE are glad to learn that the appeal of the College of Technology, Manchester, for 150,000*l*. for the extension of its buildings is meeting with a satisfactory response. The total amount subscribed for the extension of university education in Manchester includes the subscriptions to this fund as well as the 175,000*l*. or thereabouts subscribed in response to the appeal for 500,000*l*. for faculties other than technology.

NOTICE is given by the University of Bristol of the impending award of the Vincent Stuckey Lean scholarship in botany. The scholarship, value 36*l*. and tenable for one year, is open to graduates of any university on the understanding that the successful candidate undertakes research work in botany in the University. Applications must be made on or before May 22 to the registrar of the University of Bristol.

WHEN the University of Bristol was established in 1909 the city possessed one of the best-equipped engineering faculties in the United Kingdom; but since then great improvements have taken place in many other universities, and the time has come when, in order to hold its own, the Bristol engineering faculty needs further equipment. The Merchant Venturers, in whose college the faculty is provided and maintained, have decided, therefore, to undertake considerable extensions. The total cost of the alterations and additions will amount to about 11,000*l*., and it is hoped that a considerable part of the extensions will be available for use during next session, when the number of advanced students in the faculty will be very greatly increased. Last term there were 1340 students in the faculty of engineering—271 in the day-time and 1069 in the evening.

THE scientific and efficient use of steel and other metals, both in mechanical and structural engineering, depends on the collaboration of the metallurgist and the engineer. The examination of metals under a microscope is, perhaps, a matter for the metallurgist rather than the engineer, but this branch of testing of materials has now become of such importance that it is essential that the engineer should be able to follow the methods employed and to judge something of the properties of a material from photomicrographs. Most engineers have some detailed knowledge of the mechanical tests which should be carried out before a particular material is used in construction, but there are large numbers who are not in touch with modern work on metallography. We have pleasure, therefore, in directing attention to six lectures on "Metallography for Engineers," by Dr. W. Rosenhain, which have been arranged to be given at King's College, Strand, W.C.2, on Thursdays at 6 o'clock, commencing on Thursday, May 13. The lectures form part of the post-graduate work of the engineering department of the college. They are, however, open to all students and engineers. The post-graduate courses for engineers at King's College deserve to be widely known. During this session the lectures have included courses on "Metrology and Engineering Standardisation," by Mr. J. E. Sears; "Central Station Practice," by Mr. C. H. Wordingham; and "Irrigation," by Mr. N. F. Mackenzie. Arrangements have already been made for similar courses next session, and full particulars of these can be obtained from the Secretary of the college.

Societies and Academies.

LONDON.

Royal Society, April 22.—Sir J. J. Thomson, president, in the chair.—H. W. **Hilliar**: Experiments on the pressure-wave thrown out by submarine explosions. A method is described for determining the time-pressure curve at a given point in water in the neighbourhood of an exploded charge. The method depends, in principle, on measuring the growing velocity of a short steel piston exposed at one end to pressure in water. This method was applied in a comprehensive deep-water investigation of pressure-waves springing from a great variety of charges. Comparisons were made between various kinds of explosive, including gunpowder, which gives results remarkably different from those yielded by high-explosives. The general behaviour of the pressure-wave was found to approximate closely to that of a sound-wave. Its velocity was measured directly and found not to differ sensibly from that of sound in sea-water (4900 ft. sec.). The pressure falls off in

approximately simple proportion to distance from the charge. The influence which the water surface exercises on pressure at a given point can be accounted for by supposing that the pressure-wave is reflected from the surface as a tension-wave. The first part of the pressure-wave arrives at the point in question entirely unaffected by proximity of surface; but after a certain interval, determined by the difference in length of direct and reflected paths, the remaining pressure is obliterated by the arrival of the tension-wave.—E. F. **Armstrong** and T. P. **Hilditch**: A study of the catalytic action at solid surfaces (iii.). The hydrogenation of acetaldehyde and the dehydrogenation of ethyl alcohol in the presence of finely divided metals. *Hydrogenation of Aldehyde.*—Aldehyde may be converted into alcohol by passing the vapour together with hydrogen over either copper or nickel (Sabatier); but in presence of the latter metal, probably owing to the special affinity of nickel for the carbonyl group, the aldehyde is prone to undergo decomposition into carbon monoxide and methane. Copper at 200–220° effects reduction of aldehyde to alcohol smoothly, but at 300° about 50 per cent. of the aldehyde disappears and but little reduction is effected, the recovered aldehyde and alcohol being in about equal amounts. *Dehydrogenation of Alcohol.*—The yield of aldehyde obtained from alcohol as dehydrogenated in the presence of nickel is only 35 per cent., whereas, in the case of copper, not only is the ratio of aldehyde to hydrogen close to that calculated, but the unchanged alcohol may also be recovered almost quantitatively, the yield of aldehyde being about 90–95 per cent. of that to be expected from the amount of alcohol used. There is a striking absence of the secondary products observed when aldehyde together with an excess of hydrogen is passed over the metal at the same temperature.—E. F. **Armstrong** and T. P. **Hilditch**: A study of the catalytic action at solid surfaces (iv.). The interaction of carbon monoxide and steam as conditioned by iron oxide and by copper. It is shown that, like certain forms of iron oxide, prepared copper is able to effect considerable transformation of carbon monoxide and steam into carbon dioxide and hydrogen. Whereas, however, iron oxide at a suitable temperature causes the action to proceed almost as far as the equilibrium constant permits, copper does not at its *optimum* temperature effect more than 50–70 per cent. of the possible amount of chemical change; the exact proportion is to some extent a function of the composition of the original gas employed. The action of copper commences at a little more than 200° C., and up to 300° is greater than that of an iron oxide catalyst, the latter being without appreciable effect below 250° C. The difference in behaviour is explained by the hypothesis that copper effects a decomposition of formic acid (momentarily produced from carbon monoxide and steam) into carbon dioxide and hydrogen from 190° C. upwards, whereas the iron oxide alternately oxidises carbon monoxide, and is in turn in its reduced form reoxidised by the action of steam. These results are of interest, from the point of view of the general theory of catalysis which the authors have lately put forward, as illustrating the specific action of two different types of catalyst, which produce ultimately the same change ($CO+H_2O=CO_2+H_2$), but by an entirely different mechanism, involving production of intermediate systems of quite distinct kinds.—T. R. **Merton**: The structure of the Balmer series of hydrogen lines. In a previous investigation with Prof. J. W. Nicholson it was found that the separation of the components of the lines Hα and Hβ suggested that the series should be regarded as a principal series. It is now found that the structure of these lines is not invariable, but is altered by the presence of impurities, notably helium, in vacuum tubes containing hydrogen. The optimum conditions of sharpness were found in hydrogen mixed with an excess of helium and cooled to the temperature of liquid air, and under these conditions the separations of the components approximate to those appropriate to a diffuse or sharp series. The appearance of the lines in the purest obtainable hydrogen is entirely different. Measurements have been made of the separations of the components under the optimum conditions of resolution with the aid of an échelon diffraction grating, and the physical widths of the lines and the relative intensities of the components have been deduced from the measurements. It is suggested that the structure of the lines is complex, the relative intensities of the components being variable under different conditions; the structure suggested would appear to be consistent with Sommerfeld's theoretical investigations and with the results of experiment.—H. A. **Wilson**: Diamagnetism due to free electrons.

Zoological Society, April 13.—Dr. A. Smith Woodward, vice-president, in the chair.—Prof. A. **Willey**: An apodous *Amia calva*.—H. A. **Baylis** and Lt.-Col. Clayton **Lane**: A revision of the Nematode family Gnathostomidæ.—A. M. **Altson**: The life-history and habits of two parasites of blowflies.

Geological Society, April 21.—Mr. R. D. Oldham, president, in the chair.—J. W. D. **Robinson**: The Devonian of Ferques (Lower Boulonnais). In the Lower Boulonnais, between Calais and Boulogne, lies a small tract of Devonian rocks. They form a link between the Devonian beds in Belgium, France, and Germany, and those of England geographically, and also geologically, since they appear to have been formed in a narrow strait which joined the open seas extending towards the Atlantic and over Germany and Russia.—E. S. **Cobbold**: The Cambrian Horizons of Comley (Shropshire), and their Brachiopoda, Pteropoda, Gasteropoda, etc. As the study of the Comley Cambrian fossils proceeded, it became apparent that the several faunas, sketched out in 1911 on the evidence of the trilobites (Q.J.G.S., vol. lxvii., pp. 282 *et seqq.*), and their order of appearance may prove to be of more than local interest. The author consequently proposes names for the horizons, based on their fossil contents, to replace those used in his previous publications, which were often clumsy and only of local origin, though necessary until the fossils were better known.

PARIS.

Academy of Sciences, April 12.—M. Henri Deslandres in the chair.—A. **Lacroix**: The eruption of Katla (Iceland) in 1918. This volcano, quiescent since 1860, entered in violent eruption in October, 1918. The eruption was explosive, and there was no lava flow.—G. **Bigourdan**: The instruments and observations of Bailly at the Louvre. The Observatory of the Abbey of Sainte-Geneviève, at Paris.—E. **Ariès**: The equation of state of ether. The formulæ deduced from the equation of state given in earlier communications require modification for ether. The results of the modified formula are compared with Young's experimental figures.—G. **Julia**: Families of functions of several variables.—L. **Bianchi**: Pairs of surfaces with lines of associated curvature.—C. **Camichel**: The permanent *régime* in water-chambers. An account of an experimental study of the water velocities by a photographic method.—C. **Zenghelis**: The action of finely divided gases.—A. **Gascard**: The melissic alcohol of Brodie. Myricic

alcohol discovered by Brodie in beeswax, and named by him melissic alcohol. By analysis of the alcohol it is not possible to distinguish between $C_{30}H_{62}O$ (Brodie) and $C_{31}H_{64}O$, but analysis of the iodide shows that the true composition is the latter. This has been confirmed by the preparation of the hydrocarbon $C_{31}H_{64}$, and by other reactions.—**Ph. Glangeaud**: The geyser of Martres d'Artières (Puy-de-Dome). In Iceland the motive power of the geysers is steam; that of the Martres geyser is shown to be carbon dioxide.—**L. Gentil**: The mode of formation of terraces in chalk districts. A discussion of the views of Poulett Scrope. While these are in part in accord with the views of the author, it is maintained that these terraces can be formed by purely natural agencies, and are not in all cases due to ploughing, as supposed by Poulett Scrope.—**H. Vallois** and **A. Peyron**: The first stages in the development of the coccygian glomerule in man.—**A. Krempf**: Extension of the notion of oro-aboral metamerism to the internal organisation of the larva of the hexacorals (*Pocillopora cespitosa* and *Seriotopora subulata*).—MM. **Diénert** and **Girault**: The action of activated sludge on the ammonia of sewage and of ordinary water.—**R. Legroux** and **J. Mesnard**: Vitamines for the culture of bacteria. The current view that the growth of bacteria in a culture medium stops owing to the inhibiting action of deleterious substances is held by the author to be incorrect. Most media derived from animal or plant tissues contain more or less substances (hormones) favouring bacterial growth.—**A. Paillot**: The polymorphism of bacteria.—**S. Giaya**: Zinc in the human organism. The normal presence of zinc in the body is proved, the proportion increasing with the age of the subject.

THURSDAY, MAY 6.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers) (General Meeting), at 10 a.m.—Dr J. E. Stead: Inaugural Address.—E. H. Lewis: Iron Portland Cement.—At 2.30.—F. Clements: British Blast-Furnace Practice.—H. E. Wright: Chemical and Thermal Conditions in Blast-Furnace Practice.—C. H. Ridsdale: The Valuation of Ores and Iron-making Material.—J. A. Heskett: The Utilisation of Titaniferous Iron Ore in New Zealand.

ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section, conjointly with the North of England and Midland Obstetrical and Gynæcological Societies), at 10.30 a.m.—Dr. H. Tweedy and Others: Discussion on The Treatment of Antepartum Hæmorrhage.—At 2.—Dr. E. Holland and Others: Discussion on Rupture of Cæsarean Section Scar in Subsequent Pregnancy or Labour.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—R. Campbell Thompson: The Legends of the Babylonians.

ROYAL SOCIETY, at 4.30.—R. H. Fowler, F. C. Gallop, C. N. H. Lock, and H. W. Richmond: The Aerodynamics of a Spinning Shell.—Prof. W. E. Dalby: Researches on the Elastic Properties and the Plastic Extension of Metals.—C. T. R. Wilson: Investigations on Lightning Discharges and on the Electric Field of Thunderstorms.—L. F. Richardson: The Supply of Energy to Atmospheric Eddies.

LINNEAN SOCIETY OF LONDON, at 5.—Dr. G. P. Bidder: Notes on the Physiology of Sponges. *Pandorina spongiarum*, a New Species of Alga found in a Sponge.—E. J. Bedford: The British Marsh Orchids and their Hybrids illustrated by Coloured Drawings and Lantern Slides.

CHEMICAL SOCIETY, at 8.—G M. Bennett: The Mustard Gas Problem.—C. K. Ingold: A New Method of Preparing Muconic Acid.—J. W. Cook and O. L. Brady: The Dinitration of *m*-Acetotoluidide.—Y. Venkataramayya and M. V. Narasimhaswamy: A New Ozoniser.—G. T. Morgan and H. D. K. Drew: Orthochlorodinitrotoluenes. Part I.
SOCIETY OF ANTIQUARIES, at 8.30.

FRIDAY, MAY 7.

IRON AND STEEL INSTITUTE (at Institution of Civil Engineers) (General Meeting), at 10 a.m.—C. A. Ablett: Direct Current compared with Three-Phase Current for Driving Steel Works Plant.—J. F. Wilson: Notes on Slag Conditions in Open-hearth Basic Steelmaking Practice.—B Yaneske and G. A. Wood: The Reduction of Silicon from the Slag in the Acid Open-hearth Process.—At 2.30.—W. E Hughes: Some Defects in Electro-deposited Iron.—T. Baker and T. R. Russell. Note on the Ball Test.—J H Whiteley: The Distribution of Phosphorus in Steel between Points Ac1 and Ac3.—G. F. Preston. Practical Notes on the Design and Treatment of Steel Castings.
ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 4 45.—Annual General Meeting.
ROYAL ASTRONOMICAL SOCIETY (Geophysical Discussion), at 5.—Prof. R. A. Sampson and Others: The Use of Wireless Telegraphy in the Determination of Longitude.
CHINA SOCIETY (at School of Oriental Studies), at 5 30.—G S. Boulger: The History of Silk
JUNIOR INSTITUTION OF ENGINEERS, at 7 30.—J. G. McBryde Pulverised Fuel.
PHILOLOGICAL SOCIETY (at University College), at 8.—Anniversary.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Lord Rayleigh: The Blue Sky and the Optical Properties of Air.

SATURDAY, MAY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. F. Chamberlin: The Private Character of Queen Elizabeth.
BRITISH PSYCHOLOGICAL SOCIETY (at Bedford College), at 3.30.—Dr. E. W Scripture: Speech Inscriptions in Normal and Abnormal Conditions.—A. Klein: Camouflage in Land Warfare.

MONDAY, MAY 10

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—G Dobson. Instruments for the Navigation of Aircraft.
BIOCHEMICAL SOCIETY (at Chemical Department, St. Bartholomew's Hospital), at 5.30.—T. S. Hele The Synthesis of Mercapturic Acids in the Dog.—R. L. Mackenzie Wallis and H. E. Archer. Improved Methods of Analysis of the Gastric Juice.—G. Graham: The Source of the Uric Acid Excreted in the Urine after Atophan
ROYAL SOCIETY OF MEDICINE (War Section), at 5.30.—Annual General Meeting.—Surg.-Capt Bassett-Smith: Scurvy, with Special Reference to Prophylaxis in the Royal Navy.
ARISTOTELIAN SOCIETY (at 74 Grosvenor Street), at 8.—Prof. H. Wildon Carr and Others: Discussion on Bergson's "Mind-Energy"
ROYAL SOCIETY OF ARTS, at 8.—A T. Bolton: The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837 (Cantor Lecture).
INSTITUTION OF MECHANICAL ENGINEERS (Graduates' Association), at 8.—E B. W. Maitland: Chemistry as applied to Boilers
MEDICAL SOCIETY OF LONDON (General Meeting), at 8.—At 9.—Sir D'Arcy Power: Rev. John Ward and Medicine (Annual Oration).
SURVEYORS' INSTITUTION, at 8.—S. A. Smith: Rent Problems.

TUESDAY, MAY 11

ROYAL HORTICULTURAL SOCIETY, at 3.—Sir Daniel Morris: The Use and Relative Value of Trees in Great Britain.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology: The Invaders of England.
ZOOLOGICAL SOCIETY OF LONDON, at 5 30.—Dr. W. J. Dakin: Fauna of Western Australia III. Further Contributions to the Study of the Onychophora.—C. Forster-Cooper: Chalicotheroidea from Baluchistan.—Dr. W. T Calman: Notes on Marine Wood-boring Animals. I The Shipworms (Teredinidæ)
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Prof. A. Findlay: Some Properties of Colloidal Matter and their Applications in Photography (Second Biennial Hurter and Driffield Memorial Lecture).
QUEKETT MICROSCOPICAL CLUB (at 20 Hanover Square), at 7 30.
ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8 15.—Annual Meeting.—Capt. J. W. Barber: Recent Developments in Portable Types of Cinema Outfits.

WEDNESDAY, MAY 12.

ROYAL SOCIETY OF ARTS at 4 30.—G. Hewitt: Rolls of Honour.
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 8.—Major L. Hope: Some Notes on Flying boats.
BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 8.—H. Gordon: Left-handedness and Mental Deficiency.

THURSDAY, MAY 13

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. P. Graves: Welsh and Irish Folk Song.
ROYAL SOCIETY, at 4.—Election of Fellows.—*Probable Papers*.—Dr. A. D. Waller: Demonstration of the Apparent "Growth" of Plants (and of Inanimate Materials) and of their Apparent "Contractility".—W. N. F. Woodland: The "Renal Portal" System (Renal Venous Meshwork) and Kidney Excretion in Vertebrata.
LONDON MATHEMATICAL SOCIETY, at 5
INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—S. Evershed: Permanent Magnets in Theory and Practice.
OPTICAL SOCIETY, at 7.30.
INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Section) (at 28 Victoria Street) at 8.—W. E Benbow. The Chemical and Physical Properties of Iron and Steel.
ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8.30.—Annual General Meeting.—Dr. S. A. K. Wilson: Decerebrate Rigidity in Man. and the Occurrence of Tonic Fits.

FRIDAY, MAY 14.

ROYAL ASTRONOMICAL SOCIETY, at 5.
ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.—Annual General Meeting.
PHYSICAL SOCIETY OF LONDON, at 5.—Dr. F. Lloyd Hopwood: Demonstration of Experiments on the Thermionic Properties of Hot Filaments.—G. D. West: A Modified Theory of the Crookes Radiometer.—A. Campbell: The Magnetic Properties of Silicon-Iron (Stalloy) in Alternating Fields of Low Value.—T. Smith: Tracing Rays through an Optical System.
MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.
INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at King's College), at 7.—E. G. Humfress: Electrical Motor Control Devices.—The Meeting will be preceded by the Annual General Meeting.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. Karl Pearson: Sidelights on the Evolution of Man.

SATURDAY, MAY 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Frederic Harrison: A Philosophical Synthesis as proposed by Auguste Comte

WE referred last week to the harassed condition in which many scientific societies find themselves in consequence of the greatly increased cost of publication of papers communicated to them, and other additional expenses involved in the rise in prices. While the incomes remain much the same as they were before the war, the essential expenditure has become so much greater in proportion to them that the outlook is depressing to contemplate. Any increases in subscriptions which would prevent the younger scientific workers from joining learned societies, or cause a number of present members to resign would be detrimental not only to British science, but also to the extension of natural knowledge and to the welfare of mankind. The fields are ripe, and more labourers are now being trained to work in them than ever before, but if advantage is to be taken of the harvest, machinery for carrying it must be provided, and granaries built in which it can be stored. As things are at present, most of the scientific grain is cut by voluntary workers, and they are perplexed because they cannot see how they are to pay for the construction of a building in which to store it for the benefit of the community.

We are painfully reminded of this association of high motive with restricted effectiveness by the third annual report, which reached us a few days ago and is summarised on another page, of the Conjoint Board of Scientific Societies. The Board was constituted in 1916 for the purpose of "promoting the co-operation of those interested in pure or applied science; supplying a means by which the scientific opinion of the country may, on matters relating to science, industry, and education, find effective expression; taking such action as may be necessary to promote the application of science to our industries and to the service of the nation; and discussing scientific questions in which international co-operation seems desirable." In the main, these objects are much the same as those of the British Science Guild, founded by Sir Norman Lockyer in 1905, but the constitutions of the two bodies are different. Whereas the British Science Guild aims at securing the active interest and support of all members of the public who desire to promote the application of science and scientific method to national and provincial affairs of every kind, membership of the Conjoint Board is limited to representatives nominated by scientific and technical societies.

The total number of constituent societies now represented on the Board is fifty-seven, and it includes practically all the leading British societies concerned with the advancement of science and technology. The Royal Society sends four representatives, and the other societies one or two, the total number being eighty-seven, and including leaders in all departments of science and technology. We have, therefore, in the Board a federation or union which can faithfully represent joint opinion upon any scientific or technical matter of national importance submitted to it. The organisation is thus admirable for its purposes, but, as in all like British institutions, it has not the means to carry out its aims and objects. The funds of the Board are derived from contributions from the constituent societies, and these amounted last year to about 600*l.* Three societies have intimated that they are unable to make a contribution this year, owing apparently to the necessity for limiting in every possible direction the claims upon their incomes, so that this splendid organisation not only finds its activities hampered through a miserably inadequate income, but must also contemplate the future with serious misgiving. For though British science may organise itself, it has not the means to provide the motive power for the machinery it has created.

How different the conditions are in the United States may be judged from the article upon the National Research Council printed elsewhere in this issue. Like the Conjoint Board—or Federation, as it should have been called, to prevent confusion with the medical Conjoint Board—the National Research Council was started by men of science themselves, and represents their efforts to mobilise the whole strength of American science for the promotion of national well-being and the advance of science itself. While recognised by the United States Government, the Council was not organised by it, and is not supported by it. The Council's funds are derived from private sources, and the Carnegie Corporation alone has contributed no less than one million pounds, which is the amount given by our Government in 1916 in establishing the Department of Scientific and Industrial Research "for the conduct of research for the benefit of the national industries on a co-operative basis." The Council has permanent headquarters at Washington, with an executive

staff of men of science giving their whole time to the work of their respective positions. While it favours well-planned co-operation and organised effort in connection with the solution of particular problems, it is opposed to all attempts at central control of research, and to any action which may hamper the individual investigator or hinder personal initiative.

The National Research Council has thus like functions to those of our Department of Scientific and Industrial Research, but its constitution is different, and approaches more closely that of the Conjoint Board of Scientific Societies. It is not financed by the U.S. Government, and is, therefore, not a Government bureau, but a federation of the principal research agencies in the United States concerned with the fields of science and technology. Men of science in America are fortunate in securing the generous support of private benefactors for the work of their National Council. They are in consequence perfectly free to determine their own policy and to shape their own destiny, untrammelled by any of the conditions laid down by administrators unfamiliar with their spirit or their service.

Much of the misunderstanding which exists among many of our men of science concerning the Department of Scientific and Industrial Research would be avoided if the constitution of the Department were on the democratic lines of the National Research Council. We do not wish to depreciate the work of the Department in the slightest—indeed, its very important activities in some directions have often been commented upon in our columns—but we think the work could be extended and made more effective if the suspicion of bureaucratic control could be removed completely by placing responsibility for it more definitely upon the body of scientific opinion. The men who administer the grants in aid made by the Royal Society, British Association, and other scientific societies represent the fellows or members of these societies, and are not appointed by other persons or bodies. This is the case also in the National Research Council, and we suggest that our Department of Scientific and Industrial Research might relieve itself of the criticism to which it is sometimes subjected by making its Advisory Council similarly representative of scientific opinion.

Even if this change of constitution cannot be readily made, we have in the Conjoint Board a means at hand of removing existing objections. The Department might make the Board a part of its administrative machinery and pay it an annual retaining fee for service in a consultative [illegible] without giving it [illegible] executive [illegible] he Board would thus serve [illegible] between the Department and scientific societies, and science workers as a body would share responsibility with the Department in the selection of subjects for investigation which should be supported, and of societies to which these might suitably be entrusted. If our rich citizens and corporations were as generously disposed towards science and education as those of the United States, the Conjoint Board would be able to carry on its work as effectively as the National Research Council, without connection with a Department of Government. There is, however, little hope that such aid will be forthcoming, and in its absence the Department could with advantage use an organisation very similar in constitution to the National Research Council, but, unfortunately, without the funds to do like service for science.

Though the Conjoint Board was associated with the establishment of the Department of Scientific and Industrial Research, it has hitherto received little aid from the Department, and has had to carry on its very useful work mainly through its own slender resources. Among the important subjects dealt with by committees of the Board are the application of science to agriculture, national instruction in technical optics, the possible relation between magnetic anomalies and the presence of iron ores, water-power of the British Empire, timber for aeroplane construction, glue and other adhesives, Patent Laws, and the need for a joint building for scientific and technical societies. In New York there is a splendid building of this kind, and the National Research Council proposes to expend 200,000*l.* on its headquarters. Here there is nothing to compare with such accommodation for joint housing and meetings of scientific and technical workers. Science has organised itself in the Board as well as shown directions in which organised effort may profitably move. What is wanted now is what scientific workers are unable themselves to provide, namely, sufficient funds to enable the Board to continue and extend its operations on a firm financial basis. We hope the Department of Scientific and Industrial Research will be able to afford some aid of this kind, while we pray that private benefactors will arise who will place the Board in the same independent and strong scientific position as is enjoyed by the National Research Council of the United States.

Lord Kitchener as a Scientific Worker.

Life of Lord Kitchener. By Sir George Arthur. In three volumes. Vol. i. Pp. xxvi+326. Vol. ii. Pp. xi+346. Vol. iii. Pp. xi+413. (London: Macmillan and Co., Ltd., 1920.) Price 2*l.* 12*s.* 6*d.* net.

SIR GEORGE ARTHUR'S account of the work of the eminent soldier and administrator who is the subject of his three volumes is impressive not only on account of the series of successes which Lord Kitchener obtained in different and dissimilar fields, but also because of the methods by which so much was attained, for the biography is presented with such vividness that the careful reader can discern the man apart from his work. It is true that many of the episodes in the career of Lord Kitchener are mentioned with scarcely a comment, where expansion would have been desirable. Nevertheless, there is sufficient for interest and instruction in the mere relation of the stirring events in which he played so prominent a part. To have dealt with them in detail would perhaps have unduly expanded the volumes.

Kitchener possessed a variety of qualities and tastes obvious only to his intimates. Those not in intimate official relation with him in his work cannot readily form a conception of his methods. How much of his inflexibility he owed to his never having been cast in the public-school mould it is impossible to say, but to his early scientific training and his scientific tastes he no doubt owed the precision and accuracy which he required from those about him and to which he subjected himself. He was a quick thinker, readily grasping the conceptions of others, rapid in his decisions, rejecting or accepting proposals with astonishing celerity. The initiative always lay with him. It was he who gave scientific form to all his own projects. The spirit was his. It is the personality of the man which interests us as we pass from work to work.

His methods were not those of the orthodox administrator, and we cannot conceive Kitchener sheltering himself behind committees, though he frequently summoned conferences. Lord Salisbury, in his preface to the book, describes him as a man of sentiment, and pre-eminently as a man of imagination. Nothing can be more true; but it would be a mistake to suppose that, "bold and independent" as was his mind, he undervalued the opinions of experts who ventured to question his conclusions. If he never argued, he was ready to listen, and the latitude which he gave to a subordinate in devising means to an end was the measure of that confidence he reposed in his staff which was his marked characteristic. His conclusions were ever his own, and were irrevocable. Although to him the end was everything, he was less impatient of detail than is generally supposed. For precedent, of course, he cared nothing.

The truth appears to be that Kitchener's early scientific training profoundly influenced him in his subsequent career. That earnestness which he displayed in the solution of engineering undertakings was as evident in his readiness to adapt new knowledge in any branch of science to the solution of his administrative problems, and experts could readily discern the scientific method by which he reached his conclusions, for he reasoned from facts. As Sir George Arthur alludes only very briefly to the influence which Kitchener, as Commander-in-Chief in India, exerted on the reduction of disease and invaliding incidence in the Army of India, this influence is likely to be overlooked. In the history of this branch of Army administration the work of the Commander-in-Chief must always occupy a prominent place. Here he left a permanent monument to himself. It would have been strange had it been otherwise, for by his previous training and experience problems of public health were certain to appeal to him by reason of their bearing upon Army efficiency, and so we read:—

"Recent discoveries in bacteriology facilitated a systematic investigation which Kitchener, after the conference of 1905, instituted into the causation and origin of these maladies: a campaign against the house-fly, with its nidus in the night-soil accumulated near cantonments, and the mosquito—the recognised agents of the two diseases—resulted in a most significant drop of nearly one-half in the death and sickness rates. Stringent preventive regulations were issued as to sanitation, inoculation for malaris [*sic*], the purification of water, and the preservation of all food and drink from contamination; and it was peremptorily ordered that all persons—British or Native—before being employed in the preparation of any sort of eatables intended for the troops, should undergo a medical examination. Depots were also established in the hills for enteric convalescents, often carriers, who had hitherto not been sufficiently recognised as a source of danger to their comrades; and technical training in hygiene was provided for selected N.C.O.'s and men, each of these sanitary sections being supervised by a medical officer."

Similarly we see in other incidents the influence of Kitchener's early training and his scientific sympathies in many of his epoch-making measures. He was a lover of learning, and had that delight in it which we are told he endeavoured to inculcate in the students of the Staff College

at Quetta. His foundation of this college and his establishment of the institution at Khartum are evidence sufficient of his interest in education. Indeed, in his knowledge of science and in his appreciation of its utility Kitchener may be said to stand alone amongst great military administrators.

We get some clue to the Kitchener method if we bear these facts in mind, and we are enabled to see how, forsaking the practice of a scientific profession for the more ambitious sphere of civil administration and diplomacy, varying these with intervals of command of armies in peace and war, ending as an organiser of victory, he accomplished his ends with such extraordinary success.

No account of the life and work of this man will ever be complete which neglects a consideration of the influence exerted upon him by his early education. Kitchener understood the language of men of science. Consciously or unconsciously he adopted their methods. He was never out of date. We get a clue to his dislike of the bureaucrat, to his hatred of red tape, and to his contempt for precedent and of War Office methods, if we bear these in mind. We are not surprised when we hear that he "would rather sweep a crossing" than go to the War Office, for freedom to work on new lines—"always a learner," as his biographer tells us—was the very essence of the Kitchener method. When Lord Curzon and Lord Haldane characterised his organisation of the Army in India as "scientific" they were nearer the mark than perhaps even they recognised; for in the widest acceptation of the term Kitchener was a man of science, and Sir George Arthur's record of his remarkable career will find many appreciative readers in the scientific world.

The Nation's Food.

Food Supplies in Peace and War. By Sir R. Henry Rew. Pp. vii+183. (London: Longmans, Green, and Co., 1920.) Price 6*s*. 6*d*. net.

SIR HENRY REW has the happy and unusual faculty of making statistics interesting; indeed, the only time when he is less interesting than usual is when he is quoting fewer figures. In this little book he has brought together the vital statistics of British food supplies and set them out: they tell their own tale so plainly that even the ordinary non-statistical person can understand.

The book was badly needed, for it is highly important that the average man should realise the facts. Unfortunately, agricultural policy is a matter for politics and emotions, and political considerations have sometimes been more in evidence than facts or business principles. Recently a bishop wrote to the *Times* making the astonishing statement that he thought the bread subsidy was paid to farmers to encourage corn production. If such amazing lack of knowledge can occur in high places, what must be the state of the ordinary voter's mind? Sir Henry Rew's book will supply the facts for those who will take the trouble to read it.

In the first chapter he deals with the problem as it was before the war, when we had a considerable balance of money due from abroad which we could take either in food or in other commodities. The general result is shown in the following table:—

—	Weight in metric tons used in the United Kingdom per annum.[1]		
	Home-grown.	Imported.	Total.
Cereals	1,010,000	3,855,000	4,865,000
Meat	1,615,000	1,070,000	2,685,000
Poultry, eggs, game, and rabbits	170,000	161,000	331,000
Fish	715,500	132,900	848,400
Dairy produce (including lard and margarine) ...	4,704,000	527,800	5,231,800
Fruit	341,000	930,000	1,271,000
Potatoes and other vegetables	4,788,000	694,000	5,482,000
Sugar (including cocoa and chocolate)	—	1,657,000	1,657,000

[1] A certain amount of cottage and farm produce is not included in the above table.

About one-fifth of the cereals, more than half the meat, and nine-tenths of the dairy produce and of the potatoes were home-grown. The total amount of foodstuffs, home-grown and imported, was considerable, and the nation was amply supplied with food. In 1913 the main sources of supply outside the United Kingdom were, in order of value of shipments, the United States, Argentina, Denmark, Canada, India, Australia, Russia, the Netherlands, Germany, New Zealand, Austria-Hungary, France, Spain, and Ceylon.

The second section of the book deals with wartime conditions. The outbreak of the war came, no doubt deliberately, at the time when the harvest of Central Europe was practically all gathered in, and when, therefore, there were ample stocks of food for a year. On our side the wheat crop in the United States was good, and although in Canada it was short, the total North American supply was well above the average. The year 1915 opened badly, as the Russian supplies were cut off in February. The situation was saved,

however, by the heavy crops in India and Argentina. Australia considerably increased her wheat area, as did also the United States and Canada; indeed, during the first year of the war the wheat area of the world was extended by more than 18,000,000 acres. In the later years of the war the difficulty was one of transport rather than of total supply; a great effort was therefore made after the close of 1916 to increase food production in the United Kingdom. The methods and results have been discussed from time to time in these columns: the general result was a steady increase in production right up to 1918, the figures for the United Kingdom being in thousands:—

		1914	1915	1916	1917	1918
Wheat ...	quarters	7,804	9,239	7,472	8,040	11,643
Barley ...	"	8,066	5,862	6,613	7,185	7,760
Oats ...	"	20,664	22,308	21,334	26,021	31,196
Beans ...	"	1,120	924	893	474	931
Peas ...	"	374	300	261	278	441
Potatoes...	tons	7,476	7,540	5,469	8,604	9,223

This high production was obtained at a time when manures were scarce and implements difficult to repair, and when most of the skilled men were gone, their places being taken by old people, women, and children. But these substitutes worked with a will, and amply made up in enthusiasm what they lacked in skill. Even the high production of 1918 was not the maximum possible, and had the conditions persisted, even higher results could have been obtained.

The last section of the book deals with post-war conditions. Serious fears had been entertained as to the food supplies of the world; fortunately, these have not been realised, and although food is undoubtedly scarce and will remain so there is no reason to fear famine, and in the main the people of Europe, though still suffering privation, are better fed than they were in 1918. It is difficult to say what the position is likely to be in the near future, but the redeeming feature is the rapidity with which agriculture has been restarted in the devastated areas of France and Belgium. Of the 4,000,000 acres damaged by the war, nearly a quarter were handed back to the cultivators before a year had elapsed. On the other hand, agriculturists in our own country are not producing so much as they did. The withdrawal of the women from the land and their replacement by men coincided with a considerable fall in production, which is distinctly unfortunate. A further fall is anticipated as a result of the shortened hours of labour.

Other countries, however, are in a worse predicament. Russia, formerly one of the chief wheat-producing countries of the world, is unlikely to have any exportable surplus, and the position in Central Europe is still very obscure. Sir Henry Rew is not greatly perturbed, but thinks that if the social and political conditions of Europe became settled, its food production would rise to pre-war level in the course of two or three years. He is also quite hopeful about the position in this country. No student of British agriculture can ever give up hope of the future, and Sir Henry Rew is one of the leaders of the helpful band of optimists.

E. J. RUSSELL.

Differential Geometry.

The Elementary Differential Geometry of Plane Curves. By R. H. Fowler. (Cambridge Tracts in Mathematics and Mathematical Physics. No. 20.) Pp. vii+105. (Cambridge: At the University Press, 1920.) Price 6s. net.

DIFFERENTIAL geometry is a fascinating subject, because it gives us vivid and picturesque embodiments of theorems obtained by the combination of several branches of pure analysis, such as algebra, function-theory, and the infinitesimal calculus. It presents us with problems of all degrees of difficulty, from the comparatively simple theory of curvature and torsion to the provokingly difficult question of geodesics.

The present tract is just what its title indicates, except that there are a few digressions on twisted curves and on surfaces. The work has two conspicuous merits; in applying the differential calculus, the assumptions made are explicitly pointed out, and proper attention is paid to the determination of sign. The latter point is particularly important, not only because an error in sign is the one most frequently committed in computation, but also because, if a consistent determination of sign is not strictly adhered to, the formulæ of analytical and even of pure geometry cease to have general validity. Even now our text-books, especially in analytical geometry, pay so little attention to this matter that a university teacher has to spend much valuable time on this topic with intermediate students, and too frequently finds, to his disgust, that even an honours student is not so careful as he should be in the matter of sign.

Mr. Fowler's chapters on tangents and normals, curvature, contact and envelopes, leave little, if anything, to be desired. The chapter on envelopes is the most thorough-going, and suggests a couple of remarks. The elimination of α from the equations $f(x,y,\alpha)=0$, $\partial f/\partial\alpha=0$ leads to a definite locus

which may break up into a number of distinct, irreducible curves. How far any one of these curves should be considered to form a part of the envelope proper depends upon our definition of "envelope." For instance, in the author's example (p. 61)—

$$(y-a)^2 - x^3 = 0,$$

the a-eliminant is $x^3=0$, which is a cusp-locus: Mr. Fowler refuses to regard this as an envelope, but if we regard the cusps as limiting forms of nodes, we may fairly regard $x=0$ as the limit of an envelope. However, this is a matter of slight importance, because each case that occurs can be treated independently.

On p. 60 we have the example—

$$a^2f+(2a+1)h=0,$$

where the a-eliminant is $h(h-f)=0$, and neither $h=0$ nor $h-f=0$ is an envelope. If we put $(2a+1)/a^2=\beta$, the family of curves is $f+\beta h=0$, and the β-eliminant is $h=0$. It seems worth while to direct attention to this apparent discrepancy, because similar cases occur in problems of maxima and minima, etc. If, starting with $f+\beta h=0$, we replace β by $(2a+1)/a^2$, we obtain, by variation of a, the same pencil of curves; but, generally speaking, each curve occurs twice, and, as a rule, for different values of a. If $\beta=-1$, $(a+1)^2=0$, and the curve $f-h=0$ counts twice for the double value $a=-1$, and hence $f-h=0$ occurs in the a-eliminant, though it does not appear in the β-eliminant. Similar results, of a more complicated kind, occur if in $f+\beta h=0$ we put $\beta=\phi(a)/\psi(a)$, where $\phi(a)$, $\psi(a)$ are any polynomials in a.

In his last two chapters we think Mr. Fowler has rather lost his sense of proportion. In the eight pages devoted to the singular points of plane curves, scarcely anything more is attempted than a discussion of ordinary nodes and cusps; on the other hand, fourteen pages are filled with the theory of rectilinear and curvilinear asymptotes, and many of the results may fairly be said to be more interesting in function-theory than in geometry proper.

The author has conscientiously given references to the text-books which he has more or less followed in his exposition; but there is no bibliography of original papers, such as add greatly to the value of other tracts in this series. We hope that in future editions this want will be supplied; reference should at least be made to Puiseux, Weierstrass, Smith, and Halphen in connection with singular points. G. B. M.

A Garden in the Dunes.

Arcachon, Ville de Santé: Monographie Scientifique et Médicale. By Dr. F. Lalesque. Pp. viii+798. (Paris: Masson et Cie, 1919.) Price 25 francs net.

THIS handsome volume is mainly a justification of Arcachon as a health-resort, and it should appeal to those who feel the attractions of a life in France, and yet shrink from the crowd and cosmopolitan gaiety of the Mediterranean Riviera. The author is not content, however, with giving climatic temperature-charts, records of rainfall, and views of exercises on the shore and of yachting on the broad sea-basin. He has made a "regional survey" of his district, and the details of the natural history will provide matter of much interest to those who sojourn in the town. The modern "town" is a veritable garden city, especially developed in the last twenty years in accordance with Dr. Lalesque's scheme for *la cure libre*, and the separate villas provided in the *ville d'hiver* among the woods offer the patient the cheerful encouragements of family life in place of the more formal control of the sanatorium. The sand-dunes have been captured, as it were, and converted into shelters, while the fishing village on the open northern strand has been enlarged as a place for summer bathing.

Arcachon, indeed, began its career of usefulness when François Legallais, a retired sea-captain, imported from India to its desolate sand-hills the idea of the bungalow in 1823. Dr. Lalesque gives us, in a few brief lines, a sketch of this rather captivating incident in human settlement and geography. His range of vision is wide. He interests us equally in the wind-worn grains of magnetite brought northward from the great fan-deltas of the Adour system; in the "alios," a ferruginous conglomerate formed as an iron-pan in the subsoil, the permeability of which has now been triumphantly established; in the health of the oyster, an inoffensive creature, infected with typhoid germs entirely by the carelessness of man; and in the diatoms that flourish in the Lac de Cazeaux, to the actual benefit, it appears, of the water-supply of Arcachon. Dr. Lalesque in 1890 made an independent investigation of the irritating power on the human skin of the processionary caterpillar, the larva of *Bombyx pityocampa*, which inhabits the pine-trees of the coast, and he concludes that the hairs which cause urticaria are scattered from the nests of the insect by the wind. Even this affection seems trivial at Arcachon; we can imagine a visitor, temporarily inclined to irritation, being calmed by Dr. Lalesque's

enthusiasm and by his introduction to the fascinating work of Fabre.

The author shows us Arcachon, not as a modern creation on a promontory in a featureless lagoon, but as the product of great natural forces, conspiring for the health of man. The winds blow over it fraught with warmth from tropic waters; the sands are kept from wandering by the growth of aromatic pines; and the subsoils that can be traced southward across the vast Pliocene estuary of the Landes represent for the naturalist the spoils of the Central Plateau and the Pyrenees. Like Prof. Tornquist in East Prussia (NATURE, vol. lxxxv., p. 468), but with a little more professional formality, Dr. Lalesque has conquered in a field that offered little promise to the unobservant eye. G. A. J. C.

Our Bookshelf.

Iron Bacteria. By Dr. David Ellis. Pp. xix + 179 + v plates. (London: Methuen and Co., Ltd., 1919.) Price 10s. 6d. net.

IN this book Dr. David Ellis has compiled a monograph on a subject which he has largely made his own, and on which he can speak with first-hand knowledge. The group of micro-organisms discussed is important, and one of the makers of geological history, for many of the bog iron ores owe their formation largely to the activities of iron bacteria, and other iron ores may be due to the same cause. In modern life these organisms are of importance to the water engineer in relation to water reservoirs, the corrosion of conduit pipes, and the general appearance and clarity of water supplies.

The iron bacteria are a heterogeneous group of organisms, scarcely bacteria in the strict sense, belonging to several genera—Leptothrix, Cladothrix, Crenothrix, and others. The iron is collected from the water in which they live, and stored in a concentrated state as ferric hydroxide in the mucilaginous sheaths which surround their bodies. The ferruginous deposit in the membrane is often so great that it exceeds the volume of the organism itself, and the iron-impregnated membrane may persist for long after the dissolution of the organism.

Some of these organisms may occasionally multiply in a very short time to such an extent as in the course of a few weeks to change entirely the character of the water in which they are present, as was the case at Cheltenham in 1896. They may also cause encrustations in the pipes, and the group is, therefore of considerable economic importance. Six species are fully described, and methods of treatment to retard their activities in water supplies are detailed. The book is well produced and illustrated, and forms a standard work on the subject. R. T. H.

Meteorology for All: Being some Weather Problems Explained. By Donald W. Horner. With an Introduction by M. de Carle S. Salter. Pp. xvi + 184 + vii plates. (London: Witherby and Co., 1919.) Price 6s. net.

THE science of the weather may well make a wider appeal than any other branch of science, and the opening for a book which is not only scientifically accurate, but also simple and easily comprehended, is therefore very great. The author of the present work has realised that the opening exists, and has endeavoured to fill it, but his attempt can scarcely be considered successful. A few quotations will illustrate the nature of the book. In estimating cloud amounts on the scale 0–10 we are told that "if there is one cloud upon the horizon or in any part of the sky we put 1." For obtaining true bearings from a compass, "the magnetic variation in the British Isles is now 14° W." Again: "There is no more sure precursor of a gale than the 'wind-dog,' or coloured parhelion" (p. 2), which may possess some degree of truth, but scarcely seems compatible with: "When these halos are coloured and accompanied by parhelia or mock suns, they generally precede very dry weather" (p. 110). Even in such a simple matter as giving the equivalent velocities of the Beaufort numbers, the author falls into error. Some chapters are better than others, but the book can certainly not be recommended as a safe guide to put into the hands of the non-technical reader without previous knowledge of meteorology. J. S. D.

The Psychology of the Future. ("*L'Avenir des Sciences Psychiques.*") By Emile Boirac. Translated and edited with an introduction by W. de Kerlor. Pp. xiii + 322. (London: Kegan Paul, Trench, Trubner, and Co., Ltd., n.d.) Price 10s. 6d. net.

THE author deals with the more debatable classes of psychical phenomena discussed at the Paris Congresses of Experimental Psychology of 1911 and 1913, and defined as "the phenomena which, produced in animate beings or as an effect of their action, do not seem to be entirely explicable by the laws and forces of nature already known." They are classified as: Hypnoidal, including dissociation of personality and "cryptopsychism" (subconscious action); magnetoidal, which are supposed to comprise mesmerism, telepathy, and "hyloscopic" phenomena (unexplained actions of inanimate objects on animate beings); and spiritoidal, which imply agents of a psychological nature more or less analogous to human intelligence. The author proposes the term "biactinism" (bio-actinism?) for any phenomena in which a radiating influence is apparently exerted at a distance over other animate beings. For "clairvoyance," or knowledge obtained by certain individuals apparently independently of the normal senses, he prefers the term "metagnomy." On the question of the spiritistic hypothesis the author maintains a non-committal attitude.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Indian Chemical Service.

IT would, perhaps, have been better if the writer of the leading article entitled "The Organisation of Scientific Work in India," published in NATURE of February 19, had held his hand until he had obtained further information concerning the proposed organisation. The report of the Indian Industrial Commission dealt only with the general question, and left the elaboration of any scheme, if such were considered desirable, to special committees which were to be appointed at a later date. The special committees were to be given a free hand, and were left to approach the problem from an unbiassed point of view.

I was not a member of the Indian Industrial Commission, but there is nothing in the report which indicates that the Commission was in favour of a centralised system of scientific services under Government control such as that which is condemned in the article, and still more emphatically condemned by those who have contributed to the ensuing correspondence. As a matter of fact, if the Industrial Commission had recommended such a course, it would not have been supported for one moment by the Chemical Services Committee, over which I had the honour to preside. Indeed, my colleagues and I, as old investigators, would have been fully alive to the absurdity of any such proposal.

I should like to make my position clear by referring to the conditions we found to prevail in India and to the remedies which we considered necessary in order that the great natural resources of the country might be developed, but I should preface my remarks by saying that I speak for chemistry alone. Other sciences must formulate their own schemes in a manner best suited to their particular requirements.

The problem presented was twofold: First, the position of the chemists in India, and, secondly, the position of the Indian chemical industry. The position of chemists we found to be exceedingly unsatisfactory. There are in all about fifty chemists in India, and most of them are attached to established Government Services, such as forestry, agriculture, medicine, geology, ordnance, and education. In the main, the chemists, although working in the Services, were not attached to them—that is to say, they were in the position of hirelings without any claim to the advantages attaching to Service membership and without the possession of the *esprit de corps* which characterises such membership. They were, moreover, for the most part working in isolated positions in the different provinces, and were without any means by which they could press their claims on the official lay mind. In consequence, they were in many cases receiving totally inadequate salaries, and were, in fact, often regarded as some kind of freak druggist—a point of view which is even more prevalent in India than in England. It was clear that the only way by which the chemist in India could be brought to occupy a financial and social position which his education and training demanded was to place him on an equality with members of other Government Services.

The problem of the chemist was therefore a straightforward one, and was, in our opinion, open to one answer only. The other point, that of the Indian chemical industry, is perhaps rather more complex.

In the first place, there can be no question, I think, that research in chemistry must be divided into pure research and industrial research. It is true that there is no sharp line of division, but in their extreme forms pure research is carried out entirely for the advancement of knowledge, and is without obvious practical bearing, whereas industrial research is done for the advancement and development of industry. The Chemical Services Committee has recommended that pure chemical research should be left to the universities and university institutions, the obvious duty of which is to carry it out. It is not proposed that the chemists attached to university institutions should be normally members of the Service, but it is asked that the universities and university colleges should undertake to train men for recruitment into the Service in the manner recommended by the Committee.

The Committee considers that recruits should have the following training:—

(1) An honours degree in chemistry in the first or second class or its equivalent.

(2) Training in engineering (machine drawing and workshop practice) where such training has not formed part of the course under (1).

(3) One or two years' training in the methods of chemical research under someone competent to train in research.

It is not proposed to institute any system of training within the Service, excepting, of course, such practical training as will normally accrue during the working of the Service, and it is asked that the universities and university institutions should give the necessary training under (3) above. For this purpose it is recommended that maintenance and equipment grants should be given to promising students to enable them to undergo this training subsequent to graduation.

The Committee considered that, provided the trainer were a man of recognised ability, the question of the subject in which the student should be trained could be safely left to him. It agreed that instruction in the methods of chemical research, received after a course such as that given above, was the best training a man could have to develop any initiative and enthusiasm which he might possess, and that a man so trained ought to be able to turn his hand to anything chemical.

In the case of industrial research it must be remembered that chemistry in one form or another underlies most industries, and that in India the following conditions are present: (*a*) Great natural resources; (*b*) lack of scientific chemical help to develop these resources; and (*c*) a public very shy to risk capital without some real assurance of the value of the process it is proposed to finance.

Obviously, the best means for advancing chemical industry is for the firms or combination of firms engaged in the industry to establish research laboratories and to work out their own problems by the aid of their own chemists. This is an ideal which the Indian Chemical Service will be formed to foster. It will, for example, help any member of the Service who wishes to pass out into the industry, and it will second members of the Service for temporary employment to firms who wish to investigate any particular problem. But at the present time there are few manufacturers who employ chemists, and it is evident that some steps are necessary not only to demonstrate to the manufacturer the value of research in connection with his manufacture, but also to demonstrate the possibilities of any particular process to anyone wishing to invest capital and start a new industry.

Who is to do this? There is, we think, only one answer, namely, that, as it is to the interest of the State as well as of the manufacturer to develop

industry, it is the duty of the State to convince the manufacturer of the value and necessity of research in connection with his work.

The Indian Chemical Service will have research institutes in the centres of industry of every province. These will be in close touch with the works and with works conditions, and deal with questions of immediate practical importance submitted by manufacturers. They will also carry out research work in connection with the establishment of new industries, and develop a process as far as the unit factory scale. In some cases it will be necessary, in order to demonstrate the value of a process, to erect pioneer factories and work them on the complete commercial scale. Each institute will be under a director of research.

A central Imperial institute will be located at Dehra Dun. It will be under the Director-General of the Chemical Service, and contain laboratories for inorganic and physical chemistry, organic chemistry, analytical chemistry, and metallurgical chemistry, each controlled by a deputy-director. Questions involving fundamental research arising out of the work of the provincial institutes will be dealt with here, as well as the initial work in connection with the establishment of new industries. Research work of an All-India character, such as investigations on the utilisation of forest products, will also be done.

The report, which should reach England during the course of the next fortnight, should be consulted for further details. It may be added, however, that there is no official control; the Service will be worked by chemists for chemists. Chemists seconded for service with other Departments will retain their lien on the Chemical Service, but be under the control of the Department to which they have been seconded.

The provincial institutes will not be under the control of the central institute, which will act towards them in an advisory capacity only.

In conclusion, I should add that I have discussed the proposed scheme with eminent Indian men of science and prominent business men in different parts of the Empire, and they have told me that they are prepared to give it their whole-hearted support. Moreover, Sir P. C. Râv, the distinguished professor of chemistry in the College of Science, Calcutta, who was a member of the Committee and attended all its meetings, while stating at the outset that he was opposed in principle to Government Services generally, nevertheless agreed to each paragraph of the report as it was passed in its final form. He signed the report subject to a separate note in which he expresses his general approval of the scheme in the following words: "In conclusion, I desire to state that, although I consider that the days of Government Services are over and that the development of industries by the agency of a Government Service is not the most suitable way of dealing with the problem, yet I agree that, if a Government Service is constituted, the proposals of the Committee represent the best method of constituting and carrying on such a service. It is for this reason that I have attached my signature to a report with the major portion of which I am in substantial agreement."

JOCELYN THORPE.

I HAVE followed with keen interest the leading article on "The Organisation of Scientific Work in India" in NATURE of February 19, and the correspondence thereon by Profs. Soddy and Bateson, Sir Ronald Ross, and others. The note of warning has been sounded not a moment too soon. To me it appears that the Industrial Commission has not been able to make out a very convincing case for the creation of a highly expensive All-India Chemical Service—an elaborate and ordered hierarchy under the almost absolute control of a number of highly paid bureaucrats. The Services degenerate in India, the land of caste, into so many rigid and watertight compartments unamenable to healthy external influence.

The manner in which the work of the Service is to be carried on appears to me to be extremely objectionable. There is to be a Director-General of Research at the Imperial Chemical Institute, with five or six directors at different provincial centres. These officers are to have almost absolute power over the rank and file—the real workers; for not only are the directors to dictate what particular piece of research a worker is to take up, but even the publication of the work is to be subject to the consent of the Board of Control.

For the scheme to be successful the directors must be men who are conversant with almost all the different branches of chemistry, and keep in touch with the most up-to-date advances in their science. Moreover, their minds are to be occupied with swarms of problems awaiting their day to be delivered to the care of the researchers. Lastly, they are to do justice, with the impartiality of a Privy Council Judge, to each individual worker according to his work and accomplishments. Even the greatest chemists of the age would hesitate to acknowledge that they are supermen of this description.

I am afraid that the proposed Service will simply be an asylum for a few officials in favour with the Government who find administrative work much more suited to the taste than bottle-washing and other humdrum work of the laboratory, and want to legalise the exploitation of the brain and labour of the young men just coming out of the universities full of new ideas and enthusiasm for work. We shall have a number of chemists working under a peripatetic director whose claims to the post will be his seniority, which in India often goes hand in hand with incompetence. I am afraid that the so-called research work will lapse into dull, mechanical, routine outturn, and will kill all enthusiasm and initiative on the part of the actual workers. They are even, as Prof. Soddy remarks, "to be deprived of what little satisfaction and independence genuine scientific work for its own sake affords," and in many cases will have to renounce their own work for the propitiation of the directors.

It seems to be supposed that since there is a Viceroy over governors, a governor over a number of magistrates, and a magistrate over a number of petty officials, so there must be an Imperial chemist over a number of provincial directors, directors over deputy-directors, deputy-directors over sub-deputy-directors, and so on. But in the republic of science the idea of such ordered gradation is absurd. Each branch of science, notably chemistry, has now grown so vast that a particular worker, however highly gifted, can honestly tackle and follow intelligently the developments of only a minute fraction of his subject. In the quest after truth and in the exploration of new paths of knowledge every worker has to find out his own way, and it not infrequently happens that a young and unknown worker may achieve much more brilliant results than men who have grown grey in the service of science. What is wanted is co-operation, provision for more ample facilities, and the opening up of better prospects for the earnest-minded and enthusiastic workers.

In India at the present state of her scientific development, the institution of the Chemical Service on the proposed lines will be not simply a blunder, but

a crime. There is not a single technical teaching institute in the whole of India. In the universities and Government colleges there is very meagre provision for research work. The universities are just trying to emerge from mere examining bodies into centres of education, and the demand for State aid for founding chairs in experimental and industrial subjects is very great. In Bengal, the most advanced province in India, there are, technically speaking, no endowed chairs at all (except one or two founded by the generosity of patriotic citizens). Altogether we have five or six high posts in the Government colleges, but the occupiers of these posts are required only to teach, and not to do any research work. The number of research scholarships is only three or four. But the man who has done good original work, and has the good fortune to be taken into the Service, has no better prospects before him than the man who has nothing to his credit except his original degree in the university; for under the Service system promotion is by favour and seniority, not by work and efficiency.

It appears to me that the most pressing needs for India at the present moment are: (1) The foundation by the Government of a number of chairs in various branches of pure and applied chemistry in the universities, and also a large number of readerships, assistant professorships, and research scholarships. (2) The establishment of a number of technical institutes and the strengthening of the laboratories and scientific libraries. (3) The organisation of the posts so created and of the posts already existent on a professional rather than on a Service basis. (4) The replacement of the director by boards of recruitment composed chiefly of university professors, one official, and one or two non-official representatives of the public. (5) The encouragement of the foundation of scientific societies.

There should be no watertight separation between those who are engaged in special types of work in Government research institutes and those working in the university laboratories. The officials in the research institutes should be asked to maintain a life-long connection with the university in some shape or other; and the researchers in the universities may be invited, when an occasion arises, to avail themselves of the opportunities afforded in the research institutes.

PRAFULLA CHANDRA RÂY.

University College of Science, 92 Upper Circular Road, Calcutta.

The Cost of Scientific Publications.

IN the timely leading article in NATURE of May 6 on the cost of scientific publications a note is struck which goes deep to the heart of many scientific workers—editors, secretaries, and members of councils on one hand, struggling to make inadequate funds meet the greatly increased expenses, and on the other the young investigators whose papers on the results of research are being held up by the impossibility of paying for publication. It is difficult to see the remedy at the moment. Most of us will, I think, agree with you that increased subscriptions to the publishing societies, on any adequate scale, would be a hardship to many, and probably defeat the end in view by choking off members. My experience as an officer of the British Association and of several scientific societies has shown me that it is difficult enough for our younger scientific workers, such as the demonstrator class at the universities, to afford the necessary expense of joining such societies and attending the meetings. Recognising the great pleasure and advantage that one enjoyed in seeing and hearing the senior men in the subject at the first scientific meetings one attended (British Association and Linnean Society), it would be deplorable that anything should be done to render it still more difficult than it is for the younger men of to-day to attend and take part in such gatherings.

You suggest that we may have been unduly extravagant in the past in the production of our scientific publications. This may have been so to some slight extent in a few cases, but I am by no means convinced that it is general, or material, and I would deprecate any drastic change. A judicious and kindly editor, secretary, referee, or communicator of a paper may usefully do something to moderate the exuberance of a youthful author and to keep note-book details within reasonable bounds; but the scientific value of a paper may be spoilt by ruthless excision. It is not enough, in many cases, to give end-results unless conclusions are to be accepted uncritically like text-book statements. To be of value to workers on the subject in the future, the details of experiments and the statistics of observations are essential. I see therefore no remedy except the provision of considerably increased funds for publication, not from the members of the publishing societies, but from outside sources—either private benefactors or the State.

We already have certain endowments and certain annual grants for the promotion of scientific research, but I would urge the emphatic opinion that adequate publication is an essential part—the necessary completion—of any important and successful research. Some administrators of scientific funds—for example, the trustees of the Percy Sladen Memorial Fund—have acted on that view, and so far as their limited resources allow they try to see through to complete publication the researches which they have supported; but, of course, this limits to some extent their activities in subsidising further research.

The provision of a considerable endowment from which grants might be given in aid of the publication of worthy papers by the principal scientific societies would be a noble benefaction which would doubtless have an effect upon the advancement of knowledge second only to the endowment of the research itself.

W. A. HERDMAN.

The University, Liverpool, May 9.

I HEARTILY agree with the opinion expressed in the leading article in NATURE of May 6 that a Government subsidy is necessary at the present time to lessen the sudden shock of war conditions to our scientific societies, especially in the matter of printing. The case was well put by Sir Joseph Larmor in a letter to the *Times* some months ago: the blow strikes at the very roots of scientific advance, and the risk of vital damage is thus the greater because roots are apt to be buried out of sight. If the mischief be not remedied in time, it will become clearly manifest only when the fruits begin to fail.

In societies with which I am connected, and especially in the British Association, anxious study has been made of all possible economies in printing, and anything which could be regarded as a luxury is being rigidly excluded; but the printing bill will still be heavy—much heavier than before—and the excess will inevitably be subtracted from funds formerly devoted to research. Moreover, we cannot be quite easy about the omission of the items regarded as luxuries. It is a common experience that life-long influences may hang on trifles, and the natural accretions which gather round an old-established association like the British Association are peculiarly liable to contain just

the trifles which may decide events. The scientific net can scarcely be cast too wide.

H. H. TURNER.

University Observatory, Oxford, May 8.

THE appearance of the leading article in NATURE of May 6 is extremely opportune. The question is one in which the scientific world is seriously concerned, and the possibility of the high cost of production stifling the progress of science must lead us to consider what means can be found to obviate so disastrous a calamity. It is unnecessary to quote evidence of the enormous increase in the cost of printing and publication at the present time—that is well known—but the question is accentuated by many indications that the cost will go higher in the near future.

It is very undesirable that such increased charge upon the funds of scientific societies should be met by raising subscriptions. No deterrent to join societies should be advocated, for science is advanced more by individuals than by the extent of their published papers.

The question turns upon the limitations which the present state of affairs must exercise upon publications. It is quite certain that some curtailment is necessary to avoid insolvency. It is patent to all that many papers are characterised by diffuseness and redundancy, as if the value of a paper was to be judged by its length. No one who wishes to keep *au fait* with current work has time to read such: conciseness and economy of expression in the treatment of scientific papers are the desiderata.

During the war we were rationed in our food for the body, with good rather than harm to ourselves. It is now necessary that the food for our minds should be rationed. The only possible way to carry on until things are easier is to limit publication to condensation or abstracts of papers, except in special cases. It is not an easy task to make abstracts of papers so as to retain all that is essential, and with some writers it is extremely difficult to condense their diffuse communications. The point might be met by putting the responsibility upon authors and limiting them to a definite number of pages, according to the character of the paper.

Let me give an instance where curtailment in publication has resulted in great economy without loss. A few years ago the volume of Greenwich Observations extended to as many as 1400 pages. The Board of Visitors decided that it was not necessary to publish a considerable mass of observations, as these could always be supplied from the Royal Observatory to anyone who wanted them, and by this means the volume was at once cut down to less than 600 pages.

E. B. KNOBEL.

32 Tavistock Square, W.C.1, May 8.

THE leading article in NATURE of May 6 comes home to those of us who are concerned in carrying on the work of scientific societies. We are making laborious efforts to prune down diffuse contributions, and also endeavouring to increase our income by attracting new members. Many of us regard an increase in subscription rates as a device only to be contemplated as a last resort, and are in complete agreement with your article.

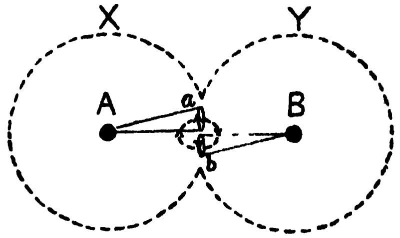
The Royal Meteorological Society is directly concerned with the question of accommodation, as well as of increasing costs of publication, and we should welcome any possibility of joining the privileged societies that are housed by Government. Failing a cash subvention for the one purpose, is it possible to urge the Government to do something for us in the other direction? I should like to press for the removal of the Civil Service Commission from Burlington Gardens. Examinations might well be held in university rooms at South Kensington or elsewhere. I do not know how many societies could find adequate room in the building if it were thus set free; but it seems to me that assistance of this kind would be, at any rate for those of us who secured it, better than a subvention towards printing expenses, and possibly easier to obtain from the Government.

WALTER W. BRYANT,
Hon. Sec., Royal Meteorological Society.

Royal Observatory, Greenwich, S.E., May 8.

Atomic and Molecular Forces and Crystal Structure.

ONE of the most difficult problems in the theory of chemical valency is to form a clear picture of the attractive forces between *similar* atoms. Lewis and Langmuir, in their theory of the cubical atom, have each attributed the single valency bond to the mutual action between a pair of electrons, and Langmuir has recently pointed out (NATURE, April 29, p. 261) that, as regards chemical considerations, such a pair of electrons may be regarded as revolving in the same orbit. This idea is closely allied to Bohr's construction for the hydrogen molecule. It should, however, be pointed out that such a construction leads to a strong paramagnetic property for molecular hydrogen, unless the electron motions are compensated by rotation of the nuclear charges. Such compensation is scarcely likely, since the magnetic moment depends on the area of the orbit described, and evidence up to date points to a nuclear radius of small order compared with that of the electron orbit, even though the latter be small compared with the conventional radius of the atom.



Model of hydrogen molecule.

Suppose X and Y are two exactly similar hydrogen atoms. Their nuclei are shown at A and B, and the negative electron orbits at *a* and *b*. The nucleus A may control the orbit *a* electrostatically and magnetically, while B controls *b*. As shown, there will be magnetic attraction between *a* and *b*, and possibly also a certain amount of electrostatic repulsion if each electron is not completely bound to its own nucleus. Equilibrium may be established for some such disposition of the charges as that indicated. We thus get a sort of fusion of the two hydrogen atoms which corresponds to the fusion of the electron orbits in Bohr's theory of the hydrogen molecule. In the present case, however, the fusion is controlled magnetically, whereas in Bohr's theory it is purely electrostatic.

The system depicted above gives a diamagnetic hydrogen molecule as required.

With more complicated systems, we can see, in a general way, how the small circular orbits will dispose themselves in pairs (Lewis and Langmuir) primarily under their mutual magnetic influences.

We might further expect that the crystallographic symmetry would be determined in a similar way by the magnetic forces due to the electrons in each atomic kernel. These electrons are drawn by mutual magnetic forces into a *space-pattern*, characteristic for each molecule, and the symmetry of this pattern is reflected in the crystalline symmetry. Thus the rigidity of the crystalline medium in different directions and the orientations of the planes of cleavage are defined in terms of the local magnetic forces (*cf. Science Progress*, No. 56, March, 1920, p. 588; Phil. Trans. Roy. Soc., vol. ccxx., A, p. 247, 1920, particularly conclusion xii., p. 289; vol. ccxv., A, p. 79, 1915; vol. ccxiv., A, p. 109, 1914). The close connection between the deportment of crystals in a magnetic field and the disposition of the planes of cleavage, as observed by Tyndall, may then be explained.

Possibly each of the electron orbits shown in the above diagram may be identified with the ring-electron of A. L. Parson (Smithsonian Miscellaneous Collections, vol. lxv., p. 1, 1915). The conception of the hydrogen molecule and the line of argument leading up to it, as indicated by the above papers, are, however, quite distinct from those described by Parson.

Wasps.

If glory be known to insects; if solid glory be measured among them, as among us, by the difficulties surmounted, the female wasp is a heroine to whom the queen bee is in no way comparable.—RÉAUMUR.

HAVING spent some time in observing wasps during the past eight years, a few notes descriptive of the results may possibly have an interest at this season when the queen wasps are searching for suitable positions in which to found new colonies. The queens usually appear in the third or fourth week of April, and about a fortnight later than the humble bees. They spend a few days in feeding, and then fly about grassy banks and hedgerows, looking for a mouse's hole or some fissure or opening in the ground likely to prove desirable habitations. They are very fastidious in making a selection. I have specially constructed places for them, but hundreds of queens have declined the invitation. In twenty-seven cases, however, the queens took up residence, and the average date was May 6. The young wasps begin to show themselves in twenty-nine or thirty days, and then a few days later the queen remains at home. During the month elapsing before the small working wasps appear the queen works hard, and performs about 1136 completed journeys to procure material for constructing cells and obtaining food for herself and young. The number given is the mean derived from eight nests.

When a queen finds herself a proper site in which to build, it by no means follows that she will succeed in rearing a colony. Only one in three have overcome the difficulties (*i.e.* nine out of twenty-seven) in my garden, for trouble was occasioned by marauding intruders such as ants, earwigs, beetles, woodlice, etc. Besides, every man's hand is turned against the wasp, and numbers of queens are destroyed every spring before the embryo nests have developed.

As to the number of wasps composing a nest, this varies greatly. The strength is pretty fairly indicated by the number flying to and fro, and I have generally kept a record of the horary rate. In regard to three strong nests, the following were the figures on different dates, a wasp flying out being counted as one, and one going in as one, so that completed journeys would be half the figures given:

Date		Two nests in 1915. per hour.	One strong nest in 1918. per hour
June	25	150	742
July	5	350	1,750
	15	670	4,800
	25	1,250	7,230
Aug.	4	2,560	8,400
	14	3,900	11,150
	24	5,200	12,060
Sept.	3	6,800	15,780
	13	4,500	6,860
	23	2,150	3,030
Oct.	3	1,250	1,620
	13	650	280
	23	250	very few

In September, 1918, I recorded an abnormal rainfall of 10·47 in., and this occasioned the virtual swamping of the nest I kept under observation in that year.

With regard to young queens, they begin to leave the nests at different times. In 1913 I noticed them first on August 21, in 1916 on August 19, and in 1918 on September 22. Two nests not at all abundant yielded in one case 990 queens and drones, and in the other 1400. A strong nest in 1915 yielded in all 1118 queens and 995 drones. There were ten tiers of cells in another nest, and six of the largest measured 10×8 in. These included 12,900 cells at least, and if each cell produced three generations this means an aggregate of nearly 40,000 wasps.

The most prevalent species of wasp in this locality is *Vespa germanica*, in the proportion of 3 to 1 of other varieties. Of twenty-seven nests, I had 1 *V. rufa*, 7 *V. vulgaris*, and 19 *V. germanica*. The latest colony I have seen in great activity was on November 5.

Wasps kill an enormous number of flies of all kinds. I found that the members of a moderately small nest of *V. germanica* in 1913 brought home at least two thousand flies per day. A very strong nest would account for twelve times as many. Man often misapprehends the benefits derived from certain forms of animate Nature. Birds are destroyed and noxious insects enabled to multiply. Efforts are ever being made to exterminate the wasp, and hordes of pestiferous flies naturally become the bane of our summers.

In spite of the popular belief, wasps are not nearly so bad-tempered and dangerous as they are supposed to be. If not obstructed or attacked they are quiet and harmless enough, and may be watched with entertainment. They are most industrious. Sir John Lubbock (later the first Lord Avebury) said: "I have been much struck by the industry of wasps"; and "On the whole, wasps seem to be more clever in finding their way than bees." Mr. T. A. Preston in the Phenological Report for 1887 (Royal Met. Soc. Journal, vol. xiv., p. 56), speaking of the wasp, stated: "It seems far superior in intelligence to the bee."

W. F. DENNING.

Dr. J. G. Bartholomew and the Layer System of Contour Colouring.

To prevent misapprehension, it would have been better if, in the sixteenth line of the obituary notice which appears on p. 238 of NATURE for April 22, the word "introduced," used by Dr. Bartholomew himself in "Who's Who," had been employed instead of "devised." Dr. Bartholomew made no claim to be the originator of the idea of indicating differences of altitude by differences of colour, but he was the first to apply this method to topographical maps.

GEO. G. CHISHOLM.

The Prismatic Astrolabe.[1]

IN the process of measuring the places of stars on the celestial sphere, or in the converse process of using these measured places to fix the position of the observer upon the earth's surface, the astronomer has at his disposal two systems of reference lines or circles upon which to base his measurements. These are respectively the vertical great circles through his zenith and the small circles parallel to his horizon, the circles of equal altitude or equal zenith distance. Using the first system, his method is to time the transit of a star across a vertical circle, almost invariably the meridian circle passing through the north and south points. If, in addition to timing the transit, he measures the altitude, he gets a complete determination of the position of the star observed, and uses both sets of reference circles, the vertical circle for fixing the time of transit, and hence the right ascension of the star, and the horizontal circle for fixing the altitude of transit, and hence the star's declination. This is the ordinary observation carried out in the observatory with the transit circle or by the surveyor in the field with the theodolite. Another method of observation which gives the same quantities, though not in the same direct form, is by the use of an instrument adapted for the recording of transits across a horizontal circle of constant altitude. An instrument of this class is the almucantar, in which horizontality is secured by the device of floating the whole in a mercury bath, it being easily seen that if either the instrument or the bath is moved round, the telescope will maintain a constant angle with the horizontal, and the line of vision will therefore always intersect an almucantar or circle of equal altitude.

Another instrument of the same fundamental type, but of an entirely different form, is the prismatic astrolabe devised about twelve years ago by MM. Claude and Driencourt. This appears to possess great merits for survey work in the field, and has earned quite enthusiastic praise from those who have used it. The one objection to its more extensive employment, the arduous labour involved in preparing observing lists of stars, has now been removed by the publication of Messrs. Ball and Knox Shaw's "Handbook" and "Diagram." We will revert to this point later, but we must first give a short descrip-

It consists essentially of a telescope with a 60° prism in front of the object glass, and a mercury trough placed so as to reflect the star on to the lower face of the prism.

The prism can be placed in either of the two positions shown in Fig. 1, from which it will be obvious that in both cases, on looking through the telescope at a star which is approaching and near to the altitude of 60°, two images of the star will be seen moving towards each other, and that these images will coalesce into one when the apparent altitude of the star is equal to the angle of the prism. In arrangement A the reflection is from the two outside surfaces of the prism, which must therefore be silvered; in B we get a total reflection from the two inside surfaces. It is further obvious that with outside reflection the angle of the prism can be given any value; the two star images will always coincide when the

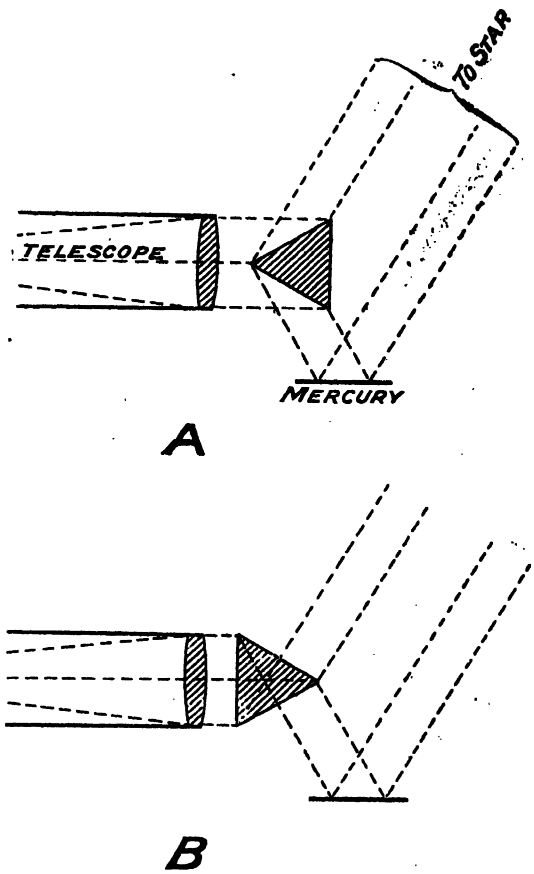

FIG. 1.—Principle of construction of the prismatic astrolabe.

altitude is equal to this angle, whereas if the rays traverse the glass they must enter and leave normal to the faces; the prism must therefore be equilateral, and stars can be observed only at the fixed altitude of 60°. The observation consists in the timing of the moment of coincidence of the two images. To allow them actually to coincide would, however, render accurate timing difficult, and far greater precision is obtained by giving the telescope a very small lateral displacement, so that the images pass close to, but not exactly over,

1 "Description et Usage de l'Astrolabe à Prisme." By Claude et Driencourt. (Paris: Gauthier-Villars, 1910.)
"Bestimmung fundamentaler Sternörter aus Höhendurchgangsbeobachtungen." By R. Trümpler. Nachrichten der K. G. der Wissenschaften. (Göttingen, 1913.)
"A Handbook of the Prismatic Astrolabe." By John Ball and H. Knox Shaw. (Cairo: Government Press, 1919.)
"Astrolabe Diagram." By John Ball. (Cairo: Government Press, 1919.)

each other; what is observed is, then, the transit of the two images over the same line of a horizontal graticule.

There is no appreciable difference in precision between the two prism arrangements. B has the apparent disadvantage that a closer adjustment of the telescope is required, the line of collimation must be perpendicular to the prism base, and the latter must be truly vertical, whereas with A the horizontality of the telescope and the symmetrical inclination of the prism faces are immaterial. On the other hand, from the practical surveyor's point of view, the use of the easily damaged silvered faces is inexpedient, and the method of internal reflection preferable. The disadvantages attaching to the necessity of more careful adjustment of telescope and prism are, moreover, more apparent than real. It must be remembered that while the actual observation involves no reading of graduated circle or micrometer, a horizontal circle is required for the purpose of directing the line of sight, so that the desired star will cross the field. The telescope and circle must therefore be levelled and adjusted as with a theodolite, and the extra labour involved in the setting of the prism is a very small matter.

As already stated, the preparation of an observing programme involves somewhat lengthy computations. These have now been made, and are available for the use of observers within a wide range of latitude. The "Handbook of the Prismatic Astrolabe" gives a succinct description of the smaller survey form of the instrument, its construction and method of use, and contains tables of all the Nautical Almanac stars down to the fourth magnitude which cross the altitude circle at azimuths suitable for observation for each degree of latitude between 55° S. and 55° N. This list gives sufficient stars for all field work except geodetic survey of the first order, for which more and fainter stars would be wanted. For these, reference must be made to the "Astrolabe Diagram," giving, for the same limits of latitude, a series of graphs from which the azimuth and time of any star crossing the altitude circle can be plotted. A comparison of the relative accuracy of the astrolabe and other survey instruments seems to indicate that it is probably capable of somewhat greater precision than a theodolite of similar telescopic power; and there is no doubt that in it we have a valuable addition to the resources of the surveyor. It cannot, however, take the place of the theodolite, being capable of determining only latitude and time, not azimuths or angles. It has therefore been urged as an objection to its more extended use that as a survey party must in any case carry theodolites the astrolabe could be taken only when the added labour of transport is unimportant. Apart from the fact that the addition of thirty pounds to the baggage of a survey expedition would be found burdensome only in quite exceptional cases, this objection does not appear to have any validity. A theodolite is capable of conversion into an astrolabe by the addition of the prism and mercury trough, and it would be easy to design these so that they could be clamped on to the front of the telescope, and the prism levelled in a minute or two. The extra weight would then not exceed a few ounces.

An attempt has been made, not, however, yet carried very far, to develop the use of this instrument for the astronomical problem of the determination of star places of high-order precision. It is very doubtful if it presents any real advantages for this work. The difficulty of making true plane surfaces is well known, and in an instrument of large aperture and high magnification the inclusion of flat reflectors in the optical system is undesirable. Furthermore, the two star images are not symmetrical, each being formed by only half the object glass, and the results show a magnitude equation, or variation with the brightness of the stars observed. This has not been specially studied in the portable survey patterns, but would probably be found even with them. Trümpler (*loc. cit.*), using an aperture of only 4·7 cm. and a focal length of 50 cm., found it conspicuously. It would increase rapidly with increase of aperture. For the present we must regard the astrolabe as a surveyor's instrument, capable in his hands of useful service, and leave any possible application to observatory work for further investigation.

E. H. H.

The Heart of a Continent.[1]

By DOUGLAS CARRUTHERS.

"CENTRAL ASIA" used to conjure up in the imagination thoughts of lonely and mysterious frontiers between three great Asiatic Empires, of strange doings in unheard-of valleys on the Pamirs, of long-dead conquerors, and of strange capitals at the back of the world. Even now, in 1920, the heart of Asia is a storm centre, for it forms the meeting-place of the civilisations of the remote past—China; of the present—Great Britain; and of the future?—Bolshevism.

Great happenings have been in middle Asia—unheard-of movements, unimagined miseries—during the past six years, when all men's thoughts have been concentrated on Europe and the Middle East. The remote highlands and deserts of Asia did not escape the turmoil. The most secluded and most apathetic native races felt the ripples of the storm in Europe. The confines of China, India, Russia, and Afghanistan have returned, by a strange coincidence, to their former place as, what may well be, the centre of a prolonged struggle, *not* between East and West, but between right and wrong.

Chinese Turkestan, or Kashgaria, is that

[1] "Through Deserts and Oases of Central Asia." By Miss Ella Sykes and Brig.-Gen. Sir Percy Sykes. Pp. xii+340. (London: Macmillan and Co., Ltd., 1920.) Price 21s. net.

part of middle Asia which forms the most westerly province of the Chinese Empire, under the title of Hsin-Chiang, or the New Province, for it is of comparatively recent occupation (since Keen-Lung, 1758). Although an integral part of the Celestial Empire, it is actually Central Asian in physical features, character, and inhabitants. This desert plain is girt on three sides by great mountain walls, yet these barriers seem to be less of a hindrance to man than is the endless desert zone which cuts it off from China proper. The Chinese rule, but the natives look to Mecca, not to Pekin, and trade with Moscow and Peshawar rather than with the cities of China. The oases belong to the group which extends from Khotan, in the east, to Bokhara, in the west.

Chinese Turkestan, then, is a colony where mild and unwarlike farmers, probably the most phlegmatic of all peoples in the world, are ruled by a handful of Chinese officials. On the north and west was a great and virile Russian Empire ever ready to overflow still further eastwards and southwards, while on the south great mountain walls arose behind which ruled the Emperor of India. Kashgar, the capital, was the only place in Central Asia where Great Britain maintained a representative. From the Caucasus to Siberia, and from Siberia to China proper, we had no official residents. It was to this far-off city that the authors went in 1915, Sir Percy Sykes to act for Sir George Macartney, the Consul-General, on leave.

We have a general account of the journey out, by way of Norway, Sweden, and Finland, Petrograd, Moscow, Tashkent, and Osh, followed by chapters on life at the British Consulate, around Kashgar, and trips to the Russian Pamirs and to the great oases of Yarkand and Khotan. These chapters, by Miss Ella Sykes, are ably supplemented by her brother's (Sir Percy Sykes) section, which deals with the geography, government, and commerce of the district, and also gives us an historical sketch which is admirable in its brevity and conciseness, for it covers in three short chapters a period from somewhere about the third century B.C. up to 1915! It should be realised that Turkestan history was shaped by Hun, Chinese, Turk, Arab, and Mongol, while the romantic names of Kutayba, Jenghiz, Tamerlane, Amursana, and Yakub Beg figure largely. Sir Percy Sykes traces the story right up to the year of his visit, and by no means the least interesting part is that which deals with the modern period. His final sentence contains much of import: "The future of Chinese Turkestan is not finally settled, but the World War, which has temporarily broken up the Russian Empire, will undoubtedly stimulate China to move along the path of progress. If so, there is hope that the condition of this outlying province of her Empire may benefit, more especially by improved communications. At the same time, there are many parts of Asia which have reason to envy the peace and plenty enjoyed by the inhabitants of Chinese Turkestan." The chapter on "The Kashgar Farmer" is noteworthy; it shows the difference between this desert land and others. Whereas other arid regions are dependent on scanty and uncertain rainfall, the great oases of the low, hot plains of Turkestan live by a sure and abundant water supply brought down from

FIG. 1.—A hunting eagle. From "Through Deserts and Oases of Central Asia."

the giant glaciers and snowfields which wall them in on north, south, and west. A certain livelihood, an ample and cheap food supply, and complete safety have produced a contented race, devoid of ambition and easily ruled. The townsfolk are much the same. Kashgar and Yarkand are still great trade centres. Since Marco Polo's day, "from this country many merchants go forth about the world on trading journeys." The old silk route ran the length of the country. All trade between China and Western Asia passed through Kashgar.

The volume ends with an account of a visit to the Russian Pamirs. For a long time the "Roof of the World" has been a forbidden land to the English hunter, but the war proved that Russian designs on India were a bogey. The author was permitted to travel and shoot in the heart of the Pamirs, while Sir Aurel Stein crossed the plateau from east to west, and penetrated to the amazingly interesting regions of Roshan and Darwaz.

The chief interest of this book lies in the fact that it recounts the impressions of a resident in a country which has so far been described only by the passer-by. Even a glimpse of life in the only city of Central Asia where the British Empire retains a representative should commend it to the reader. For years the post has been held by Sir George Macartney. Far removed from the nearest Englishman, cut off from India, isolated and alone, he has upheld the honour of the Empire, using prestige instead of Cossacks, and relying on his unrivalled knowledge of the East. Sir Percy Sykes had his work cut out to fill the gap satisfactorily, but his life experience in Asia served him well, and he has allowed us to see something of it.

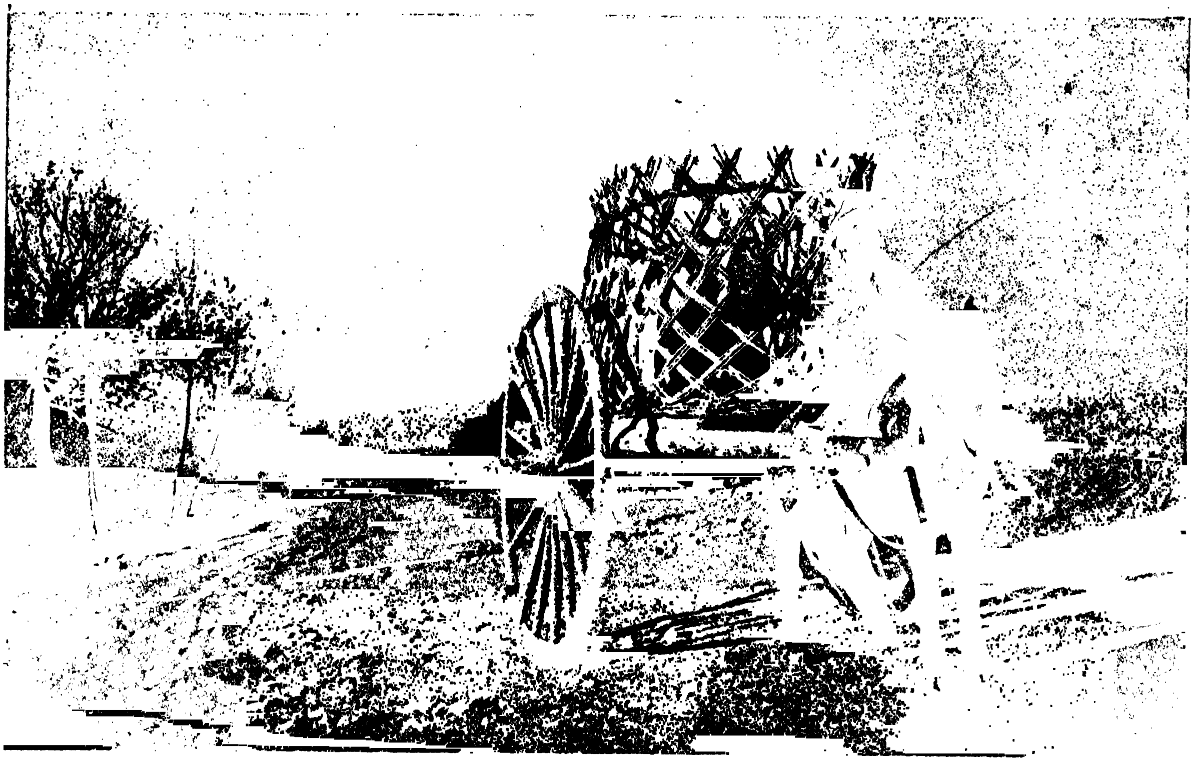

FIG. 2.—Cart used in the Osh district. From "Through Deserts and Oases of Central Asia."

The United States National Research Council.

By PROF. VERNON KELLOGG.

THE National Research Council is a co-operative organisation of men of science in America for the special purpose of promoting fundamental research in the physical and natural sciences, the application of scientific knowledge in the industries, and the training of research workers, all for the sake of the general advancement of science and the increase of the national strength and well-being. It was organised in 1916, under the auspices of the National Academy of Sciences, especially to help make the scientific resources of the country available to the Government in the solution of pressing war-time problems involving scientific investigation. As now reorganised on a permanent peace-time footing, its membership of about 250 is largely composed of duly appointed representatives of about forty major scientific and technical societies of America, with a group of administrative officers and necessary office staffs, resident in Washing-

ton. These officers are appointed for but one year at a time, and it is expected that most of the offices (chairmen of divisions, etc.) will be filled in rotation by men drawn from the scientific faculties of the universities, the staffs of large scientific institutes, and the research laboratories maintained by the industries.

Although during the war the Council was largely supported by the Government, it is now entirely supported by private funds. A gift of 5,000,000 dollars has recently been made to it by the Carnegie Corporation. Part of this money, perhaps a million dollars, will be used to erect a building in Washington for the offices, conference rooms, etc., of the Council and the National Academy of Sciences, and the remainder will constitute a permanent endowment for the Council. This endowment will provide for the administrative expenses of the organisation, leaving the funds necessary to aid in the support of the large co-operative scientific projects of research, which the Council hopes to stimulate or establish, to be found, as the needs require, from wealthy men or philanthropic foundations interested in the promotion of the investigation of the fundamentals of science and from the industries interested in promoting the extension of scientific applications.

The Council as at present organised includes thirteen divisions, seven representing the various major lines of science and technology, and six representing general relations. The first seven are divisions of the physical sciences, engineering, chemistry and chemical technology, geology and geography, the medical sciences, biology and agriculture, and anthropology and psychology. The general relations group includes a division of foreign relations, a Government division (including representatives of each of the major scientific bureaux included in the Government Departments of War, Navy, Commerce, Labour, Agriculture, State, and Treasury), a division of States relations, one of educational relations interested especially in the research conditions and activities in the colleges and universities of the country, a division of research extension especially devoted to the extension of research to the industries, and a research information service intended to act as a general national clearing-house for information concerning the scientific *personnel* and scattered research work of the country.

Affiliated with these various divisions are many special committees and sub-committees which concern themselves with various special phases and specific projects of scientific investigation. The present number of these committees approximates fifty. There is also a special Research Fellowship Board, which has at its disposal through the period from May 1, 1919, to June 30, 1925, the sum of 500,000 dollars, appropriated by the Rockefeller Foundation for the Maintenance of National Research Fellowships in Physics and Chemistry. Thirteen of these fellowships have so far been instituted.

The National Research Council is thus neither a great operating scientific laboratory nor an organisation possessing large funds from which to make direct gifts to individual scientific investigators or scientific laboratories, but an institution for the purposes of stimulating and organising scientific research in America, and of promoting international scientific relations in all possible ways. It is specially interested in organising scientific effort along co-ordinated co-operative lines. It hopes to encourage vigorous attack on major problems too large and many-sided for the individual investigator working alone, and often requiring the co-operation of numerous investigators and laboratories representing several different but allied lines of science. In the applications of science it is especially interested in such problems as bear directly on the promotion of the national strength and well-being.

Among the many projects now in course of organisation or actual development are an extensive study of food and nutrition in charge of a committee including many of the leading American physiological chemists and experts in human and animal nutrition; a study of high explosives, begun during the war; the preparation of critical compendia of physical and chemical constants; a study of the fundamental scientific problems of baking, of ceramics, of steel alloys, of synthetic drugs, of the chemistry of colloids, of sewage disposal, of forestry, of fertilisers, etc. An extensive investigation of tropical biology, including especially tropical medicine, is in course of organisation. A detailed survey of the research conditions in all the colleges and universities of the country, in which research work is now being done or probably can be done in the near future, is in active progress. A committee on mental measurements has recently completed an elaborate series of trials of group tests on several thousand children, and has prepared, and is about to publish, a set of recommended tests for use for classification and grading in the common schools of the country. These tests are adapted from the sets developed by the Council's special psychological committee on Army tests during the war. Altogether, the Council is getting under way a good deal of important research work, and promises to be an organisation of much influence in the promotion of American activity in the advancement of science.

Obituary.

MARLBOROUGH R. PRYOR.

SOME fifty years ago Marlborough Robert Pryor, who died at Weston Park, Stevenage, on April 3, was well known in scientific circles at Cambridge, and seemed likely to rise to a high position in those studies. He was a man of many interests and great adaptability of mind, who, though he was rather early diverted to executive business, never lost his interest in those parts of it which were connected with science. Educated

at Eton, he entered Trinity College, Cambridge, taking his degree as B.A. in 1870, and that of M.A. three years later. It is rather remarkable that he did not "go in for honours," for he was then so conspicuous a student of natural science as to obtain successively a scholarship and a fellowship by examination in those subjects, being in each case the first elected to these distinctions in Trinity College.

In Pryor's days natural science was beginning to look up in Cambridge, though it did not yet lead directly to a degree, for its first Tripos examination, when the list was headed by Prof. Liveing, was in 1858, four men being in the first class, and two in the second. Until 1869 the total number in all the classes rarely exceeded ten, and sometimes sank down to four, and on three occasions no one was in the first class. Things have changed since then, for in the days immediately before the war there would be some 120 or more in the three classes, as there doubtless will be again. But from 1870, when Pryor's name would have appeared had he gone in for the examination, the names of men who have since won distinction are more often found in the lists—such as H. Darwin (now Sir Horace); W. M. Hicks, of Sidney, who turned from science to theology and became Bishop of Bloemfontein; Garrod and Lydekker, Teall, Martin, Frank Balfour, M. Hartog, and Sollas, now professor of geology at Oxford, not to mention others.

Pryor, however, so far as I know, wrote no papers of importance on strictly scientific matters. I do not find his name in the earlier volumes of NATURE, which began to appear in November, 1869, nor is it in my catalogue of collected papers on scientific matters, which goes back to a still earlier date. Yet he won distinction at Cambridge, not only by his academic successes at Trinity, but also from all who met him there in scientific society. One could not be long with him without getting the impression that one was talking with a clear-headed man of strong intellect, who looked at things all round before he spoke of them, and expressed his views quietly and deliberately. He had a large store of knowledge and was a keen critic, yet never anything but kindly. He took a special interest in ornithology, and was a frequent member of that circle of young men of science which the late Prof. Alfred Newton delighted to gather round him on Sunday evenings after dinner in his rooms at Magdalene, where much tobacco was consumed and any amount of natural history was talked. These gatherings indirectly extended the interest felt in that subject in Cambridge, and perhaps were an even greater incentive to its study than any formal teaching by the professor.

Soon after taking his degree Pryor left Cambridge and entered on a business career in London, settling down near Stevenage, where he inherited from an uncle an estate called Weston Park. At first he joined a firm of South American merchants, and became a director of some important joint-stock companies. The two with which he was most closely and permanently connected—and they were businesses requiring especially a clear head and a sound judgment—were the Sun Insurance Office and the Sun Life Assurance Society, to each of which he became chairman, holding those offices until 1918. The prosperity of these institutions was the chief work of his later life, and he carefully studied the problems of insurance in all its branches. It is said that his views were strong and his business ideals high, and that nothing short of the strictest practice would ever satisfy him. But he was regarded with real affection by the other members of the boards, and to the younger of them his great store of knowledge on all sorts of subjects was a constant cause of wonder. Still, he kept up his connection with his college and his university, for he frequently came up to be present at special social gatherings in the former, and in later years took an active part in the endeavour to collect funds to advance teaching in the latter, which was gratefully acknowledged in a resolution passed the other day. Besides all this, he was a good Spanish scholar, and had paid much attention to church architecture, especially in Hertfordshire. He married Miss Alice Solly, of Serge Hill, in that county, and has left six daughters and one son, Col. Pryor, D.S.O., who served in France and Italy.

So, to the regret of many friends, Marlborough Pryor is gone. He has left no conspicuous record in the scientific annals of his generation, as once seemed probable, but no one can say that his life was wasted, because, while some men can serve science the better by taking a prominent lead in this or that branch of it, others can do it by the catholicity of their knowledge and interests. Marlborough Pryor was among the latter, and each has his work to do; each is helpful to his generation; for the one raises the towers; the other, as he did, builds the walls.

T. G. BONNEY.

MR. J. A. POTT, who died recently at the age of fifty-five, was a scholar whose importance as a moving force in his generation cannot be estimated by the popularity of his work during his lifetime. As an archæologist he contributed to the *Antiquary* for 1904 two articles on Neolithic and other remains found near Harlyn Bay, Cornwall. He made the first translation into English of two important treatises of Thomas à Kempis, entitled "The Founders of the New Devotion," and the "Chronicle of the Canons Regular of Mount St. Agnes." These were followed by two series of graceful renderings of poems from the Greek Anthology. Just before his premature death, due to overwork in recruiting during the war, he had completed a verse and prose translation of the Epigrams of Martial, which will shortly be published. A fine scholar and man of letters, Mr. Pott exercised an inspiring influence over a large group of friends drawn from circles largely differ-

ing both socially and intellectually. The charm of his personality depended on the fact that, happy as he was himself in living, he was still happier in making his life a blessing to others.

MR. A. H. HIORNS, who died on April 17, was for many years head of the metallurgical department of the Birmingham Municipal Technical School. He commenced teaching metallurgy about 1875 in branch evening classes under the auspices of the Birmingham and Midland Institute. Later he was transferred to the central school, and was so successful as a teacher that he was granted leave of absence in 1882 and 1883 to study at South Kensington under Sir W. Roberts-Austen. On his return to Birmingham he organised a new metallurgical department at the Birmingham and Midland Institute. As the work expanded, it was transferred to the Birmingham Municipal Technical School, where the enthusiasm and geniality of Mr. Hiorns gathered an ever-increasing number of students. Mr. Hiorns contributed papers on metallurgical subjects to various scientific societies, but was best known as the author of a number of students' text-books, which have had a wide circulation, and include "Practical Metallurgy and Assaying," "Metallography," "Metal Colouring," "Iron and Steel," "Mixed Metals," etc. He retired from teaching some eight years ago, and the latter part of his life was spent chiefly in rural pursuits.

T. T.

MR. T. W. BACKHOUSE, of West Hendon House Observatory, Sunderland, who died on March 13 in his seventy-eighth year, devoted a large part of his life to scientific pursuits, and carried on for more than sixty years a series of meteorological and astronomical observations. He was a frequent contributor to our correspondence columns, and a most successful student of those minute differences in the appearance of the sky or of the atmosphere that escape untrained observers, who prefer to consult the barometer rather than natural phenomena. Four volumes of Publications were issued by him from his observatory, and the last, in 1915, summed up the accumulated records, extending over fifty years, of his skill and vigilance as an observer. In 1912 Mr. Backhouse published a valuable new catalogue of 9842 stars, containing all stars conspicuous to the naked eye. The catalogue was designed specially to afford assistance in the observation of meteors, to which Mr. Backhouse himself gave much attention; but it has been found useful by many other astronomers. His last communication was on the subject of the January meteors (Quadrantids) of 1917 (NATURE, vol. c., p. 313). Mr. Backhouse became a fellow of the Royal Astronomical Society in 1873, and of the Royal Meteorological Society in 1892.

Notes.

THE PRINCE OF WALES having graciously consented to be nominated as an honorary fellow of the Royal Society of Edinburgh, the nomination was made at the last ordinary meeting on May 3, and the election will be carried out, according to regulation, at the ordinary meeting to be held on June 7.

THE Croonian lecture of the Royal Society will be delivered by Prof. W. Bateson on June 17 upon the subject of "Genetic Segregation."

MR. J. H. LESTER has been elected chairman of the chemical section of the Manchester Literary and Philosophical Society for the session 1920–21.

NOTICE is given by the Chemical Society that applications for grants from the society's research fund must be made, on forms supplied, to the assistant secretary, Chemical Society, Burlington House, W.1, on or before June 1.

MR. WILFRED H. PARKER has been appointed director of the National Institute of Agricultural Botany. The institute, including the Official Seed-testing Station for England and Wales (the director of which is Mr. Saunders), will be housed at Cambridge in a large building which will be completed by next summer. Meanwhile the temporary office of the institute is at 72 Victoria Street, London, S.W.1.

THE Salters' Institute of Industrial Chemistry invites applications for fellowships of the annual value of 250*l*. from those who in October next will have completed three years' training in chemistry and desire ultimately to enter upon an industrial career. The applications, including particulars of the candidates' training and war service, must be sent to the director of the institute, Salters' Hall, St. Swithin's Lane, E.C.4, by, at latest, July 1.

A REPORT by Dr. A. Mearns Fraser, Medical Officer of Health for Portsmouth, upon the prevention of venereal diseases was noticed in NATURE of March 25 (p. 114). The Society for the Prevention of Venereal Disease now informs us that the Portsmouth Borough Council has decided that steps shall be taken to educate the male inhabitants of the borough in the facts put forward by Dr. Fraser as to methods of prevention by immediate self-disinfection.

SCIENTIFIC visitors to the Royal Academy's exhibition this year will be much interested in the fine presentation portrait of Sir Clifford Allbutt painted by Sir William Orpen. The picture hangs in the first gallery and bears the inscription: "Sir Clifford Allbutt, K.C.B., M.D., F.R.S., Regius Professor of Physic in the University of Cambridge; President of the British Medical Association. Presented to him by his Profession, 1920." A proof of the mezzotint engraving of the portrait is exhibited in the room devoted to engravings, drawings, and etchings.

THE Department of Scientific and Industrial Research announces that the third Conference of Research Organisations will be held to-morrow,

May 14, at 3 p.m. in the lecture theatre of the Institution of Civil Engineers, Great George Street, Westminster. An introductory address will be given by the Marquess of Crewe, who will be chairman of the conference, and it will be followed by papers on "The Relation of Research Associations to Existing Institutions for Research," by Dr. A. W. Crossley, and on "The Staffing of Research Associations: Salaries and Superannuation," by Mr. J. W. Williamson.

IN an article in the *Times* for May 3 Mrs. Ayrton presents what must appear to be a formidable indictment of the War Office for neglect in regard to the use of the anti-gas fan. It is stated not only that there was great difficulty in getting the device considered, but also that, after its efficacy had been demonstrated, its adoption was delayed. Further, it is alleged that the supply of fans was never adequate, that the method of using them was never properly taught, and that to the last less efficacious measures were adopted in preference to the fan. It is suggested that this neglect on the part of the War Office entailed death to numbers and untold suffering to countless others. Many charges of grave neglect have been levelled against the War Office. The present one, however, is peculiar in being a charge, not against the military element, but rather against the experts who were associated with the Gas Service. It is well known that the Anti-Gas Service of the Army was, in the field, in the research laboratory, and on the instructional side, in most of the chief appointments, staffed by well-accredited men of science, and that both at the central laboratory in France and in London competent men were keenly on the alert to test and improve defensive measures. In view of this, it appears scarcely likely that Mrs. Ayrton's allegations will be accepted without question, and it is much to be desired that some plain statement of the facts should come from the men of science whose intelligence and humanity are implicity assailed in her article.

ON the occasion of a luncheon given by the *Times* last week to celebrate the first attempt to fly from Cairo to the Cape, Dr. P. Chalmers Mitchell, who accompanied Capts. S. Cockerell and F. C. Broome as scientific observer, made some interesting remarks on the value of aviation in scientific exploration. The aviator has an opportunity denied to the explorer on land of seeing the general lie of the country and the broad features of its topography. The view of a large tract of country makes it possible to appreciate and explain features which would be puzzling when seen piecemeal or partially by the surface traveller. This applies particularly in a country such as Africa, where much detailed exploration has been done in places before the broader features are understood. Dr. Chalmers Mitchell believes that geographical and geological exploration will benefit widely by the use of aeroplanes. Another interesting point he emphasised was the unexpected number of natural aerodromes which the flight revealed. Several times when the machine was forced to make unexpected descents, suitable places were found. Dr. Chalmers Mitchell pointed out that a re-survey of the Cairo-Cape route from the air made in order to locate these natural aerodromes would save the cost of many intermediate stations that are being planned.

THE trustees of the British Museum have arranged to purchase the whole of the collection of Lower Palæozoic fossils made in the Girvan district by Mrs. Robert Gray, of Edinburgh. The number of specimens is more than 38,000. Fossils from these rocks are scarcely represented at all in the British Museum, and very meagrely even in the Scottish museums. Apart from the specimens collected some fifty years ago by Mr. Robert Gray and now in the Hunterian Museum, Glasgow, there is little worth considering outside the present Gray collection. Mrs. Gray has diligently continued the work begun by her late husband, so that the whole series is admirably represented in her collection. She has also taken pains to get her material described, and it forms the foundation of a long series of memoirs. Noteworthy among these are the well-known work by Nicholson and Etheridge on "The Silurian Fossils of the Girvan District" (1878–80), the Palæontographical Society's monographs by Cowper Reed, W. K. Spencer, and Ida Slater, and the large memoirs in the Transactions of the Royal Society of Edinburgh by Reed and by Bather. In spite of these publications, the collection is known to contain undescribed material scarcely less in extent and importance. The situation of the rocks near the northern limit of the Ordovician and Silurian sea, and the richness of certain beds of a facies different from their representatives elsewhere, have led to the inclusion of a number of rare forms in the fauna. Among these are a new and strange cystid, Cothurnocystis; starfishes carrying back to the Ordovician plans of structure previously regarded as Devonian; echinoids among the oldest known and of a type hitherto unrecognised before the Upper Silurian; a remarkable edrioasteroid, Pyrgocystis; beautiful examples of the supposed cirripede, Turrilepas; and two new species of the very rare Helminthochiton.

THE thirty-first annual Conference of the Museums Association will be held in Winchester on July 5–8, under the presidency of Sir Martin Conway, Director-General of the Imperial War Museum. The meeting this year is a joint conference with the French Museums Association, and among those who have signified their intention of attending are M. Hughes Leroux (senator), M. le Prof. Louis Roule (Paris Museum), M. le Prof. Vayssière (president of the French Museums Association), M. Fernand Guey (treasurer of the French Museums Association and director of the Museum of Fine Arts at Quimper), Dr. A. Loir (secretary of the French Museums Association), and a delegate from the French Association for the Advancement of Science. The mornings during the conference will be devoted to the reading and discussion of papers, and the afternoons to visits to places of special interest to museum workers. The subjects for discussion at the conference are: (1) The Public Libraries Act of 1919, and its effect on the future policy of museums; (2) the status and remuneration of museum curators and their staffs; and

(3) the desirability of a diploma for museum curators and the necessary course of training. In addition, the following papers have been promised: (1) "The Lighting of Picture Galleries and Museums," by Mr. Hurst Seager, vice-president of the New Zealand Institute of Architects; (2) "The Selection of Pictures for Municipal Art Galleries," by Mr. E. Howarth, curator of Sheffield Public Museums; and (3) "A Central Government Department for Museums and Art Galleries," by Dr. F. A. Bather. Mr. R. W. Hooley, Earlescroft, St. Giles's Hill, Winchester, has undertaken the duties of local secretary, and a small committee under the chairmanship of the Rev. S. A. McDowall, Winchester College, has been formed to arrange the programme of local visits.

THE next informal meeting of the Chemical Society will be held at Burlington House on Thursday, May 20, after the conclusion of the formal business of the ordinary scientific meeting. An exhibit demonstrating the methods of controlling soil organisms now being investigated at the Rothamsted Experimental Station will be shown by Mr. and Mrs. D. J. Matthews. This exhibit will include specimens of the soil organisms and the cultivation of these on artificial media. The effect of toxic substances on organisms and of the relationship of chemical composition to toxicity, with specimens illustrating effective doses of certain typical substances with a given quantity of soil, will also be shown. Dr. Marie Stopes will exhibit specimens and microscopic slides of fusain, durain, clarain, and vitrain, the four main constituents of banded bituminous coal. Mr. E. R. Thomas will show some experiments illustrating the influence of temperature, concentration, solvent, constitution, and catalyst on the rate of chemical change.

A SHORT article in our issue of March 11, p. 56, describing a magnetic disturbance which occurred on March 4–5, mentioned that aurora had been observed at Aberdeen on March 4, but considerably earlier than the commencement of the disturbance, and so presumably not directly connected with it. This seems to have been the only observation of aurora in this country on either March 4 or 5. A letter, however, which we have received from Prof. A. S. Eve, of Montreal, mentions a brilliant aurora as having been observed there between 1 a.m. and 2 a.m. G.M.T. on March 5, and so synchronous with the magnetic storm. Commencing with isolated patches, the aurora appeared for a short time in the form of an arc, and ended in a curtain display. This incident leads Prof. Eve to inquire whether there is in existence "an organisation for recording, with accurate timing, auroræ in both northern and southern hemispheres, and, if so, where can the records be obtained?" So far as we are aware, no such records exist. The question seems to merit the consideration of the recently instituted Section of Terrestrial Magnetism and Electricity of the International Geodetic and Geophysical Union.

THE Marlborough College Natural History Society, which has been in existence for fifty-six years, is a notable example of the good work which an association of schoolboys can perform under competent guidance. The report of the society for 1919 announces the retirement from the post of president of Mr. J. C. Alsop, who carried on the work with success during the period of the war. In botany 205 species, in ornithology 85, and in entomology 223 have been recorded. Lichenology shows a good record, though the subject has been little worked in this country, but the monograph on British species recently published by the British Museum and edited by Miss A. L. Smith may stimulate interest. A good course of lectures delivered by eminent specialists and numerous papers read by members during the year form an interesting feature of the report, which is carefully prepared, and furnishes a good example for the authorities of other schools in Great Britain.

DR. CHARLES SINGER has reprinted an address delivered before the British Academy (Proceedings, vol. ix.) on "Early English Magic and Medicine." The history of medicine is sharply divided into the Dark Age period and that which followed the arrival of the Arabian learning, the remnant of Greek science which survived in the Moslem world. Dr. Singer deals only with the pre-Arabian material. In England the latter has survived from two channels, manuscripts and folk-lore. Greek medicine reached the barbarian peoples of the West at a time when the scientific system of Greece was in complete decay, and it came through Latin channels. In dealing with magic Dr. Singer remarks that ecclesiastical elements are found throughout the whole corpus of Anglo-Saxon medicine and magic. Native Teutonic magic and medicine may be distinguished from imported elements of classical, ecclesiastical, or Salernitan origin by the presence of four characteristic elements: the doctrine of specific venoms, the doctrine of the Nines, the doctrine of the worm as a cause of disease, and, lastly, the doctrine of the elf-shot—all of which are fully described. "The Celtic influence in the Anglo-Saxon material is elusive and yet pervasive, but the difficulty of tracing it may be a result of the common heritage of the two cultures and the common external influences to which they were both subjected."

MESSRS. SUTTON AND SONS, Reading, have published an interesting contribution to the literature on seed electrification. This bulletin (No. 11) presents the results of a number of germination and field tests carried out in 1919 with seeds of carrot, swede, cabbage, and mangold. The best-known process of seed electrification, viz. the Wolfryn process, consists in immersing the seeds in a solution either of common salt and water or of calcium chloride and water, through which an electric current is then passed. After this treatment the seeds are dried at a temperature of 100° F., and they are then ready for sowing. Obviously two processes are here involved, seed immersion and seed electrification, and the Reading experiments were designed primarily to test the value of the Wolfryn process, and secondarily, if there are advantages, to decide whether they are due to the immersion, to the electrification, or to both agents combined. Tests were made with untreated seeds, with seeds electrified by the Wolfryn process, with seeds soaked in a solution of sulphate of am-

monia, and with seeds soaked in a solution of salt and water, the strength of the solution being the same as that used in the Wolfryn process. After immersion the seeds were dried at 100° F. and then sown. Regarding the tests as a whole, they do not reveal any advantage from seed electrification, the only possible exception occurring in the case of mangolds, where the germination of the electrified seed was 94 per cent., compared with 82 per cent. for the untreated seed and 86 per cent. for the seed soaked in the salt solution, while in the field tests the electrified mangold seed yielded 62 lb. per pole more than the untreated seed. In all other cases either the electrified seed gave a lower yield than the seeds treated in other ways, or the increase following electrification was so small as to be negligible.

THE Government of India is now considering the principles under which the census of 1921 is to be undertaken synchronously with those of the nations of civilised Europe. Hitherto the reports have included much valuable anthropological material, but this is found to be in practice of little value to the bureaucracy. The time, it is said, has come for a scientific demographic census, one which collects such statistical details as will throw light on all the problems of population, such as the causes which increase or decrease peoples or sections of peoples in numbers, by sexes, in efficiency and capacity for progress. More, we want to know the real causes why the Moslem population increases at a faster rate than the Hindu, and the causes of the excess of male births, of the variability of sex mortality, and of polygyny and polyandry. To carry out such a scheme it will be necessary to work in close collaboration with European experts. In former census reports the mass of anthropological material made them a happy hunting-ground for European workers. If future reports are to be confined to inquiries of a sociological kind, we trust that efforts will at once be made to continue the ethnological survey on wider lines. The scheme initiated by Lord Curzon has led to little result; and while Madras, the Central Provinces, Burma, and the Punjab have issued some important publications, practically nothing seems to have been done after twenty years' incubation in Bombay, Bengal, and the United Provinces.

THE *Meteorological Magazine* for April contains an article on "Climates of the British Empire Suitable for the Cultivation of Cotton," by Mr. C. E. P. Brooks. Details with respect to rainfall and temperature of a cotton-growing climate are given for various British Possessions and Colonies. It is stated that the essential features are: (1) The mean annual temperature should not be below 60° F. (2) The mean temperature of the warmest month should exceed 80° F., or the mean of the three warmest months should exceed 77° F. to get the best results; this condition, however, is not so important as the first. (3) The interval between killing frosts (or droughts) should be at least 200 days. (4) The annual rainfall should not exceed about 60 in. for good crops, though cotton of a poorer quality can be grown in much wetter climates; unless irrigation is possible, the annual fall should not be less than 23 in. (5) There must be plenty of bright sunshine. A dull and humid atmosphere is particularly unfavourable to the cotton plant.

MR. G. W. LAMPLUGH'S address as president of the Geological Society of London appears in the Quarterly Journal of that Society, vol. lxxv., part 1, published in January, 1920. Its theme is that studies of the thicknesses of English sedimentary series show that an anticlinal uplift is the sequel to deposition in a gradually deepening trough. Hence the greatest thicknesses of strata are now found near the escarpments, from which the beds thin away towards the margins of the former trough. The Weald, the Jurassic uplands, the Trias, and most of our Carboniferous rocks are cited as examples. The Jurassic beds beneath the Weald still retain the synclinal structure; but the "partial recovery" of the trough is marked as we pass upwards through the Wealden series to the Chalk. The sections given provide much material for thought.

THE latest addition to the series of Special Reports on the Mineral Resources of Great Britain, issued by the Geological Survey, is vol. xv. on "Arsenic and Antimony Ores," by Henry Dewey. As neither of these substances is produced in any very important quantities in this country, the report is necessarily a brief one, though the subjects are treated quite thoroughly. In the case of each metal there is given a general account of the mode of occurrence and of the distribution of its ores, followed by a detailed description of all the mines that have produced any noteworthy quantity. There is practically no antimony at all produced in Great Britain, but Cornwall and Devon still rank as relatively important contributors to the world's output of arsenic, much of this being obtained as a by-product from Cornish tin-mines. As has been pointed out by Sir Aubrey Strahan, the main value of this report lies in the fact that it has brought together in a convenient and readily accessible form a quantity of information previously scattered through a number of publications, which is thus rendered readily available to those interested in the various industries which make use of the metals here discussed or of their compounds.

THE April issue of the Journal of the Institution of Electrical Engineers contains the paper read by Mr. R. S. Whipple at the joint meeting of the institution and the electro-therapeutics section of the Royal Society of Medicine on electrical methods of measuring body temperatures. After describing the modern resistance thermometer and the thermo-electric couple methods of measuring temperature, he comes to the conclusion that for ordinary work records of body temperature and its variation can best be obtained by means of a resistance thermometer placed in the rectum. For more accurate work a thermo-electric couple with a photographic recorder must be used, especially if rapid or minute variations of temperature are to be detected. The resistance thermometer may be made of platinum wire of about 1/20 mm. diameter, have a resistance of about 140 ohms, and be used with a moving-coil galvanometer in a resistance

bridge with arms of about the same resistance. A suitable thermo-electric couple is provided by copper and constantan, an alloy of about 60 per cent. copper and 40 per cent. nickel. A moving-coil galvanometer of coil resistance 10 ohms or less is suitable, with a balancing resistance placed in series to give a convenient scale deflection.

It is a sign of the spirit which we have so long worked to encourage, to find on opening last month's issue of *Beama*, the excellently produced journal of the British Electrical and Allied Manufacturers' Association, an article by Mr. E. B. Wedmore urging the importance of co-operative scientific research. Mr. Wedmore points out how the war has taught us the value of concerted action, and shows that combined rather than individual research facilities are particularly necessary in view of the present shortage of scientifically trained technical men. Among articles which follow, indicating some of the enormous industrial structures already raised on foundations of scientific endeavour, is one by Mr. W. E. Hughes sketching the many uses to which the electro-deposition of metals has been put. An interesting example is the building up of worn engine parts, such as crankshafts, by deposits of iron—a practice developed by the Royal Air Force in face of some difficulty during the war. The author, however, points out how the serious lack of educational facilities has hampered British progress in these branches of electro-metallurgy. Another interesting article by Mr. A. B. Searle deals with the preparation of tungsten and its important uses in the filaments of modern incandescent lamps and of the three-electrode ionic valves upon which many of the recent developments in wireless telegraphy are based. Notwithstanding the large amount of research that has led up to the present processes, the author characterises them as "making the best of a bad job." If means could be found for melting the purified tungsten economically, the quality of the filaments would be greatly improved. Unfortunately, however, this cannot be done at present, he concludes, owing to the extraordinarily high melting point of the metal (more than 3000° C.) and the difficulty of heating it to this temperature out of contact with carbon.

That "small things often very considerably affect the destinies of great ones" is the appropriate motto chosen to introduce a paper on lubricants read by Mr. G. F. Robertshaw at a meeting of the Institution of Petroleum Technologists on April 19. One object of the paper was to urge a plea for uniformity in the methods of examining lubricating oils. At present there is a diversity of practice which is liable to produce confusion and uncertainty in judging lubricants from the physical and chemical data obtained in testing them. For instance, there are half a dozen kinds of instruments used for determining the viscosity of oils, and the results are expressed in different terms, depending upon the particular viscometer employed. Hence an appeal is made that the absolute viscosity, or some convenient multiple or sub-multiple of it, should uniformly be used as the standard method of expression. The paper also, it may be noted, affords a convenient reference to the somewhat extensive literature upon lubrication. Without compiling a complete bibliography, the author directs attention to many useful sources of information, historical, scientific, and practical. On the question of "oiliness"—a property possessed by good lubricants which at present cannot be specified in definite terms—it is remarked that this property is not necessarily proportional to viscosity. Whilst the late Sir Boverton Redwood's dictum is still true, that viscosity is our most valuable test of lubricating quality, there yet remains the fact that for the same viscosity the fixed vegetable and animal oils have usually a greater "oiliness" than mineral oils.

A new view of the nascent state is put forward by C. Zenghelis in the *Comptes rendus* of the Paris Academy of Sciences for April 12. Experiments are described which show that the chemical activity of such gases as hydrogen, oxygen, nitrogen, or carbon monoxide is increased by bringing them in contact with solutions in very minute bubbles. This fine state of division is obtained by forcing the gas through cartridges of paper, the pressure inside the cartridge being so adjusted that the gas does not bubble through, but reacts with the dissolved body in the pores of the paper. Before each experiment a blank was made with each cartridge alone to prove that the paper had no action on the solution. Under these conditions hydrogen was proved to reduce mercuric chloride to calomel, potassium nitrate to nitrite, carbon dioxide to formaldehyde, and substances giving a sugar reaction. With oxygen gas ammonia was oxidised to nitrous acid, and methyl alcohol to formaldehyde. With nitrogen and hydrogen sufficient ammonia was produced in half an hour to give a reaction with Nessler solution. Carbon monoxide reduced iodic acid and sodium molybdate. All these reactions took place at ordinary temperatures. Fuller details of the experiments will be published later.

Prof. A. N. Whitehead is publishing almost immediately through the Cambridge University Press the Tarner lectures delivered by him in November last. The volume will be entitled "The Concept of Nature," and form a companion to the same author's "Enquiry Concerning the Principles of Natural Knowledge." It will, however, be less mathematical than the earlier work.

The Cambridge University Press announces the publication in June of "The Influence of Man on Animal Life in Scotland: A Study in Faunal Evolution," by J. Ritchie. As the title implies, the book will deal with the bearing of man upon the character and composition of the fauna of Scotland. It will be fully illustrated and contain eight maps.

The latest catalogue (No. 401) of Mr. Francis Edwards, 83 High Street, Marylebone, W.1, gives particulars of 757 books on the Far East—China, Japan, and the Malay Archipelago; also of the Far North-East of Asia, including Siberia and Kamtchatka. Many of the works are scarce, but the majority are listed at greatly reduced prices. The catalogue will be sent free upon request.

Our Astronomical Column.

CONJUNCTION OF MARS WITH SPICA.—Interesting, though not extremely close, approaches of Mars to the bright star Spica Virginis will occur on May 22, when Mars will be situated 2½ degrees north of the star. On that night the planet will pass the meridian at 9.21 G.M.T. at an altitude of about 30 degrees. On succeeding nights Mars will be observed to the N.N.W. of the star, but on June 2 will become stationary, and thereafter move slowly eastwards. On June 12 he will again be in conjunction with Spica Virginis, and about 1°37′ N. of the star. Mars will cross the S. meridian 10 minutes before sunset on the latter night, and a good view will not be obtainable of the planet and star until 9 p.m. G.M.T. and afterwards. Mars will be much the brighter of the pair, and visible at an earlier time than the star. The two conjunctions will form attractive and striking configurations.

THE DUPLICITY OF ν GEMINORUM.—There is an article on this star by Dr. Bernewitz in *Astr. Nach.*, 5041. The orbit as a spectroscopic binary was investigated in the Publications of Ottawa Observatory (vol. iv., No. 19). The period is 9·6 years, and the value of $a \sin i$ is 1,400,000,000 km. This large value suggested that it might not be impossible to detect the duplicity visually. It has been examined with the 65-cm. refractor at Berlin-Babelsberg Observatory by Dr. Bernewitz, Dr. Bottlinger, Prof. Guthnick, and Mr. F. Pavel. All agree that the image is distinctly elongated. Neighbouring stars of similar magnitude appeared perfectly round, so that it is concluded that the effect is not instrumental. On examining ν Geminorum through increasing thicknesses of a dark wedge it was found that before it disappeared it became round; they conclude from this that the companion is about 1 magnitude fainter than the primary. This difference removes uncertainty as to the quadrant. Dr. Bernewitz and Mr. Pavel each measured the pair on five nights, and their respective results are:

Date	P.A. °	Distance. ″
1920·208	116·2	0·14
1920·205	124·3	0·16

They state that the spectroscopic results indicate that the star is now near elongation. If measures can be obtained over a sufficient arc of the orbit, it will be possible to deduce the parallax and mass. The spectral type is B5, so that a mass-determination would be of particular interest.

KODAIKANAL OBSERVATIONS OF PROMINENCES.—Vol. i., part 2, of the Memoirs of Kodaikanal Observatory has lately been distributed. It contains a full description, with numerous photographs, of the prominence observations made by Mr. and Mrs. Evershed, and a discussion of their distribution and motion. Their preponderance at the sun's eastern limb, which many observers have noticed, is difficult to explain except as an earth effect. It will be remembered that Mr. Evershed has recently noticed another sign of an earth effect in the distribution of line-of-sight velocities in the photosphere.

It is pointed out that besides the principal prominence zones, which coincide with those of sunspots, there are also high-latitude zones. The prominences in these are less active than the equatorial ones; they frequently appear as pyramids, or rows of round patches. Their wave of activity begins in latitude 50°, soon after sunspot maximum; it travels poleward, reaching the pole about the next maximum and dying out there. It is suggested that the change in the corona round the poles, which takes place in the sunspot cycle, may be connected with this prominence fluctuation.

The rotation of the prominences has been studied at Kodaikanal; it is found to be more rapid than that of the photosphere. Line-of-sight velocities and disc observations of long-lived prominences agree in supporting this. It is concluded that the prominences are so tenuous that the free path of the atoms is infinite. Their luminosity "is due to the internal energy of the atoms, perhaps derived mainly from absorption of the intense solar radiation."

Leonardo da Vinci.[1]

By EDWARD MCCURDY.

WITH the list of war inventions may be numbered Leonardo's researches in aviation. He pursued this subject for many years. His studies range from the consideration of the primary causes of flight in birds and other winged creatures to the invention of a screw propeller and the consideration of its applicability to aerial navigation. He also made an actual attempt. Jerome Cardan, the physician who made a horoscope for Edward VI., in his work "De Subtilitate" refers to an unsuccessful attempt at flight made by Leonardo da Vinci, and adds somewhat dryly, "He was a great painter." A sentence on the cover of Leonardo's manuscript, "Sul Volo degli Uccelli," written in 1505, has been interpreted as referring to this attempt. "The great bird," it runs, "will take its first flight upon the back of the great swan, filling the whole world with amazement, and filling all records with its fame; and it will bring eternal glory to the nest where it was born."

This enigmatic utterance may be somewhat more comprehensible if it is remembered that *cecero* is the Italian word for swan, and "the back of the great swan" may therefore be interpreted as a reference to Monte Ceceri, a hill to the south-west of Fiesole, from which it is believed the flight took place.

From the meagre records of the attempt we pass to researches in theory and construction.

The material falls naturally into two groups, the first being a series of investigations of the laws which govern the power of flight as manifested in Nature by birds and other winged creatures, the second consisting of deductions from these principles in the construction of a mechanism which should be capable of sustaining and being worked by man. The interdependence of the two parts of the inquiry is stated with great succinctness in a passage in the Codice Atlantico:

"A bird is an instrument working according to mathematical law, which instrument it is within the capacity of man to reproduce with all its movements, but not with a corresponding degree of strength, though it is deficient only in the power of maintaining equilibrium. We may therefore say that such an instrument constructed by man is lacking in nothing except the life of the bird, and this life must needs be supplied from that of man.

"The life which resides in the bird's members will, without doubt, better conform to their needs than will that of man, which is separated from them, and especially in the almost imperceptible movements which preserve equilibrium.

"But since we see that the bird is equipped for many obvious varieties of movements, we are able from this experience to deduce that the most rudimentary of these movements will be capable of being comprehended by man's understanding; and that he will to a great extent be able to provide against the

[1] From a discourse delivered at the Royal Institution on Friday, March 19. Continued from p. 309.

destruction of that instrument of which he has himself become the living principle and the propeller."

In the analogy thus drawn from Nature to the problem before him, Leonardo has anticipated the attitude of modern research.

In his construction of the instrument he finally attempted to combine the type of the lark soaring with its wings open with that of the bat as it descends. He does this by the introduction of *sportelli* (trap-doors or shutters) in the surface of the wings, whereby, as he says, "the wing is full of holes as it rises and closes up when it falls." The shutters should have rims of cane and be covered with starched taffeta to render them airtight. Perhaps it was after the Monte Ceceri attempt that he wrote on a page of MS. B of the Paris manuscripts, "Try the actual instrument in the water, so that if you fall you will not do yourself any harm." It may also have been the failure of this attempt that caused him to search for a fresh source of motive power to take the place of that exerted by the muscles of a man. On 83 verso, MS. B of the Paris manuscripts, there is a drawing of a large screw constructed to revolve round a vertical axis, and a note explains its intended use: "If this instrument made with a screw is well made—that is to say, made of linen of which the pores are stopped up with starch—and is turned swiftly, the said screw will make its spiral in the air, and it will rise high."

Leonardo adds that a small model may be made of cardboard, with the axis formed of fine steel wire bent by force, and that this when released will turn the screw. To his drawing of this instrument the architect Luca Beltrami has—to me, as it seems, justly—applied the word "aeroplane."

Another page in the Codice Atlantico (311 v. d.) of unique interest contains three studies of artificial wings, a name, and a note that the machine is to be made, not with *sportelli*—that is, shutters—but united. The natural interpretation is that the note refers to a commission for the construction of a machine for flight, with regard to which the patron, Gian Antonio de Mariolo, has expressed a desire that the wings should be such that no wind would be able to pass through them as it would if they had shutters, *i.e.* should be like the wings of the bat.

Leonardo's researches in natural and applied science cover so wide a field, and specialisation in these days has so divided knowledge into watertight compartments, that properly to gauge the value of his contributions to scientific research would require a combination of many trained intelligences. But it is not possible to devote a number of years to the close study of all that concerns Leonardo without becoming imbued with the conviction of the complete oneness of his work and method. The dominant purpose which animates him, whatever the nature of the problem, is to investigate, to examine, and to define primary causes. His pen reinforces his practice. "Nature," he says, "is constrained by the order of her own law, which lives and works within her." Again, "There is no result in Nature without a cause; understand the cause, and you will have no need of the experiment"; and "Nature is full of infinite causes which were never set forth in experience."

With Leonardo the latter end of this search forgot the beginning. His intellectual curiosity into the origins and causes of all created things is revealed in infinite variety in the thousands of pages of his manuscripts, compact, as has been said, "of observation, of prophecy, of achievement," and in his triple legacy forming a record probably unequalled, certainly unsurpassed, by that of any other man in the history of the world. For consider what he was! Painter, sculptor, engineer, architect—all these to the wonder of his contemporaries. His manuscripts reveal that he was no less distinguished as physicist, biologist, and philosopher. But in the field of science he was essentially a forerunner. The results that he achieved must be reckoned as small compared with his grasp of basic principles, with the vistas that he opened up, and with the unerring instinct which he displayed in choosing the true method of investigation.

All Leonardo's writings connected with science seem, as it were, fragments of a larger purpose, charted, defined, explored, but never fulfilled, of which his researches in anatomy, zoology, physiology, embryology, and biology are the allied and component parts. Discerning the essential unity of man and the animals —"because," as he says, "all land animals have similar members—that is to say, muscles, nerves, and bones—and these members do not vary at all except in length and thickness" (MS. G, 5 verso)—he may be said to have founded comparative anatomy. Drawings now at Windsor show the gradations of the human type merging into that of various animals. Leonardo tracks the mystery of life from the conception and the fœtus through growth to maturity, and so to the gradual wasting of the tendons and all the physical phenomena of death.

"I have dissected," he says, "more than ten human bodies, destroying all the various members, and removing even the very smallest particles of the flesh which surrounded these veins without causing any effusion of blood other than the imperceptible bleeding of the capillary veins. And, as one single body did not suffice for so long a time, it was necessary to proceed by stages with so many bodies as would render my knowledge complete; and this I repeated twice over in order to discover the differences."

The drawings made in the course of these investigations, now in the Royal Collection at Windsor, were examined in the time of George III. by the famous surgeon William Hunter, who, approaching them with natural professional distrust, thus made the *amende honorable* :—

"I expected," he says, "to see little more than such designs in anatomy as might be useful to a painter in his own profession. But I saw, and indeed with astonishment, that Leonardo had been a general and deep student. When I consider what pains he has taken upon every part of the body, the superiority of his universal genius, his particular excellence in mechanics and hydraulics, and the attention with which such a man would examine and see objects which he has to draw, I am fully persuaded that Leonardo was the best anatomist at that time in the world." Although he does not fully explain its mechanism, he evidently knew of the circulation of the blood a hundred years before Harvey gave the knowledge to the world. "The heart," he wrote, "is a muscle of great strength; the blood which returns when the heart opens again is not the same as that which closes the valve."

The depth and variety of his researches in other branches of natural science may be inferred from the citation of a few instances in which he anticipated the results of investigations associated with other names. Either before, or at latest during such time as Copernicus was laying the foundations of his heliocentric theory by study at Bologna and Padua—a theory afterwards brought to completion and published in his work, "De Revolutionibus Orbium Cœlestium," in 1543—Leonardo had enunciated the ruling principle of it in a line in the manuscripts now at Windsor, "Il sole non si muove" ("The sun does not move").

A hundred years before Maestlin, who is credited with the discovery, he had defined the obscure light of

the unilluminated part of the moon as due to reflection from the earth's surface.

In the search for hidden laws and causes the scientific problem followed hard upon the artistic problem. The study of perspective led to that of light and shade, and so of optics—the study of the structure and functions of the eye, as being the instrument by which light and shade are perceived. He made a model of its parts, and showed how an image is formed on the retina, thus refuting the currently accepted belief of the eye throwing out rays which touch the object it desires to examine. He described also the principle of the *camera obscura* ninety years before Porta developed the idea in practice.

In mechanics he enunciated the theory of inertia, afterwards demonstrated by Galileo, and relegated the theory of perpetual motion then current to the same category as astrology and necromancy. He refound the wisdom of Archimedes, and demonstrated his theory of oblique forces applied to the arm of the lever, afterwards associated with the name of Galileo. Following on Archimedes's conception of the pressure of fluids, he showed—a century and a half before Pascal—that liquids stand at the same level in communicating vessels, while if the two arms are filled by different liquids the heights will vary inversely as their densities.

Leonardo is at once artist and man of science in his treatment of, and interest in, water. He studies its properties and power of movement under conditions varying from the action of the tides of the ocean to the laws which regulate the movement of water in siphons—a subject on which he notes his intention of writing a treatise. He follows its transformation into vapour, rain, dew, snow, and ice. It winds mysteriously in wonder-working coils through the landscape backgrounds of his pictures. He traces the infinite shapes it assumes, falling in violence of movement in spirals and eddies, circling like the loop of a swallow's flight, something of the artist's sheer delight in the creation of beauty of form mingling with the purpose of the man of science to wrest from this variety its underlying principle. Or again, as engineer he harnesses its power, studying to divert its channels either in menace of war or for purposes of commerce or irrigation.

In considering a geological problem his method is entirely deductive. "Since," as he says, "things are far more ancient than letters," he turns from authority to the testimony of things themselves. "Why," he asks, "do we find the bones of great fishes and oysters and corals and various other shells and sea-shells on the high summits of mountains by the sea just as we find them in low seas?" The fact that the cockles were living at the time when they became embedded in the strata—this being evident from the shells being found in a row in pairs, while in other places the dead are found separated from their shells and all cast up together by the waves—is cited as proof that water formerly covered parts of the earth which are now far above the level of the sea, and that this condition continued for a period of more than the forty days of the Deluge, because, as the cockle travels along a furrow at the rate of three or four braccia daily, it could not in forty days have proceeded from the Adriatic to Monferrato in Lombardy, a distance of 250 miles. By an investigation of the cuttings formed by the Arno in the successive strata of which the shells are found, he shows the gradual changes in the crust of the earth, and, following on the track of this knowledge, he essays the construction of the map of Italy in days remote beyond record, but of which the earth remains a living witness.

His special interest in botanical study may be traced back to the earliest period of his artistic work. Vasari tells of a cartoon, intended for tapestry, of the sin of Adam and Eve in Paradise, where was a meadow with innumerable plants and animals, "of which in truth one could say that for diligence and truth to Nature divine wit could not make the like." He mentions a fig-tree as of special excellence for the foreshortening of the leaves and the disposition of the branches, and also a palm in which the roundness of the fan-like leaves was shown with marvellous art. His description suggests minute attention to detail on the part of the artist based upon a profound study of Nature, and these are the characteristics which find expression in Leonardo's many exquisite studies of plants and flowers, and in the treatment of the herbage in the Virgin of the Rocks in the Louvre. His study of botany was in inception an integral part of his treatise on painting, botany being as necessary as anatomy, in order that the painter might have the requisite knowledge of form and structure. But here also the artist's power of observation of the varied beauty of earth's raiment of plants and flowers is merged imperceptibly in the mood of the man of science who saw in Nature not only form and colour, but, above all, light, which St. Augustine called "the queen of colours," and uses Nature's profusion as a background whereon to study the incidence of light and shade.

Leonardo's researches in structure are so exact and so scientific in method as to anticipate the results of subsequent inquiry, as, for instance, in the knowledge his writings reveal of phyllotaxis—the law of quincuncial arrangement of the leaves on the stem—promulgated in 1658 by Sir Thomas Browne in his "Garden of Cyrus." In like manner the discovery that the age of a tree may be told from the number of concentric rings visible in a section of its trunk, with which more than a century later the names of Nathaniel Grew and Marcello Malpighi are associated, is contained in a passage in Leonardo's "Treatise on Painting" (Ludvig, 829). Leonardo also states in the same passage that these rings vary in thickness according to the greater or less amount of humidity of each year.

I have attempted here to summarise a few of the results attained in the course of this investigation. The breadth and variety of their scope may serve to recall the remark of Francis I., who is recorded by Benvenuto Cellini to have said that "he did not believe that any other man had come into the world who had attained so great knowledge as Leonardo."

Aeronautical Research.

THE announcement by the Air Ministry of the future arrangements for aeronautical research and education marks an important stage in the history of the subject. The course followed was indicated in a White Paper, noticed in NATURE of March 4, p. 14, containing the report of a Committee on Education and Research in Aeronautics. The chairman of that Committee, Sir Richard Glazebrook, is now head of the new Aeronautical Research Committee and Zaharoff professor at London University. He was for twelve years chairman of the late Advisory Committee for Aeronautics under the presidency of the late Lord Rayleigh, and it may fairly be claimed that the new advance in the direction of the co-ordination of research in a large subject is a consequence of the success of the work of the earlier body. The Advisory Committee for Aeronautics had the assistance of such eminent men of science as Sir Horace Darwin, Sir Joseph Petavel, Sir Dugald Clerk,

Sir Napier Shaw, Mr. F. W. Lanchester, and Sir George Greenhill. The new Committee differs considerably from the older one in its *personnel*, and indicates an apparent break in continuity. This is not wholly the case, for many of the new members of the Research Committee have for some time been members of sub-committees of the Advisory Committee. It was inevitable that the end of a strenuous period, such as that which brought the war to a close, should be taken as a suitable time for the withdrawal of the older members from some of their activities, and this has happened to a great degree in the case of the members of the Advisory Committee for Aeronautics. The place of such members is taken by specialists in aeronautics together with one or two men of science of wide experience.

It was recommended, in the report referred to, that funds should be provided for a school of aeronautics at the Imperial College of Science, South Kensington, to which institution the Zaharoff chair of aviation was attached. The Treasury has approved of the necessary funds being provided, and steps have now been taken for the formation of the necessary educational staff. The Committee's scheme recommended that this staff should include, in addition to the Zaharoff professor, whole-time professors of aerodynamics and airship construction, together with part-time teachers on design, materials, aero-engines, meteorology, navigation, and airships, and a whole-time junior staff. Mr. L. Bairstow, a former student of the college, has been appointed to the chair of aerodynamics. His work at the National Physical Laboratory on the stability of aircraft is well known and constitutes an important advance in aeronautical engineering. Mr. Bairstow is a member of the new Aeronautical Research Committee, and this dual position—like that of Sir Richard Glazebrook—should afford ample facility to enable the Research Committee to supervise the educational work of the new school.

In general the scheme proposed attempts to provide a common meeting-ground for everybody connected with aeronautics. As a central body responsible for advice and criticism and for the broad lines of policy in research, the Advisory Committee for Aeronautics proved to be of the greatest value. It had no direct executive powers, although the National Physical Laboratory had departments in aeronautics provided solely for carrying out the wishes of the Committee.

The experience gained is apparently considered by the Air Ministry to have justified an extension of powers, and, in particular, the contact with full-scale research at Farnborough and elsewhere is made of the same character as that previously holding for the model work at the National Physical Laboratory. In addition, the Committee has intimate relations with the Imperial College for educational needs. The terms of reference to the Committee and the delimitations of the respective responsibilities of the Air Ministry and the Department of Scientific and Industrial Research give some indication of the very complex arrangements contemplated. Control in all directions is divided, and it is some consolation in these troubled times to find the whole of the essential elements of aeronautics combining to give a fair and generous trial to a scheme without definite rules, *i.e.* to a scheme which assumes helpful co-operation as the basis of success. Whatever difficulties may appear in this direction can only be known later, but it may be hoped that the new Committee will be a worthy successor to the Advisory Committee for Aeronautics and so help to confirm a healthy precedent in the relations of industry and research to the Departments of State.

Conjoint Board of Scientific Societies.

THE report for the year 1919 gives evidence that the Board continues to discharge useful work. During the year there was a danger that supplies of casein and glue would fall short, and that aeroplane manufacture would suffer thereby. The Board came to an arrangement with the Air Group of the Ministry of Munitions, and carried out a research into the nature, functions, and manufacture of adhesives. This resulted in the discovery of two new adhesives, one possessing very remarkable properties, and the other prepared from a waste product of which there was a large supply in the country throughout the war. In addition to this, Dr. Schryver and his colleagues devised improvements in the manufacture of casein which effect a considerable saving in material and an improvement in its quality.

The Committee on the Water-power of the Empire, with Sir Dugald Clerk as chairman and Prof. A. H. Gibson as secretary, drew up a second report, in which it is able to claim that it has stimulated interest in water-power investigations in many parts of the Empire. In India, Ceylon, British Guiana, Australia, the Union of South Africa, and the East Africa Protectorate steps are being taken by the appointment of commissions or committees, or by preliminary investigation and survey, to estimate the water-power supplies which will be available, and in several instances the committee has been asked to give guidance and assistance. Much new development is taking place in New Zealand. A proposal has been put forward to hold an Imperial Water-power Conference in London. Attention is directed to the general lack of facilities in universities and technical institutes for the specialised training of young men in hydro-electric engineering.

The committee of which Sir Robert Hadfield is chairman has sent deputations to interview Sir Alfred Mond and Mr. Stanley Baldwin (on behalf of the Chancellor of the Exchequer) in order to put forward its opinion that there is a great need for better and more centralised accommodation for the technological and scientific societies.

The Patent Laws Committee drew up a series of recommendations, which were adopted by the Board and transmitted to the Federation of British Industries for use in its endeavour to introduce modifications into the new Patent Laws.

An elaborate report on the advisability or otherwise of the compulsory adoption of the metric system, drawn up by a committee with Mr. Wilson-Fox as chairman and Mr. A. R. Hinks as secretary, was discussed at a special meeting of the Board called for the purpose. The report, which envisages boldly the actual practical difficulties which would confront compulsory adoption, especially during the war, is shortly to be published on the authority of the committee, accompanied by a series of criticisms on the part of the scientific and technical societies to which it has been submitted.

Other pieces of work summarised in the report relate to such subjects as the supply of timber for aeroplanes, the establishment of geophysical and petrophysical institutes, and the place of science in warfare.

The Board has also taken its share in the discussion of the formation of national and international research councils, and in advocating the publication of a work devoted to the mineral resources of the Empire. The Bulletin, which is printed and issued to the conjoint societies and the members of the Board, gives in a comprehensive form a forecast of the meetings of the societies and an early announcement of the papers to be read thereat.

Agricultural Development in the West Indies.

THOSE interested in tropical agriculture will find much worthy of attention in a paper on "Tropical Departments of Agriculture, with Special Reference to the West Indies," written by Sir Francis Watts, Imperial Commissioner of Agriculture for the West Indies, and published in the Journal of the Royal Society of Arts (February 20). The paper contains a very interesting account of the evolution of tropical Departments of Agriculture, pointing out that these Departments had their origin in the botanical gardens which were started in the larger islands in the eighteenth century, and also in the mission gardens which the early missionaries cultivated around their stations. The author traces the decline of the British West Indian sugar industry, and the efforts to revive it and to stimulate agriculture by the formation of botanical departments in the smaller islands. Economic conditions, however, became worse, and in 1896 the West Indian Royal Commission was appointed, and its report marks a period in West Indian history. As an outcome of this report the Imperial Department of Agriculture was constituted, the expense of which was met by Imperial funds. The policy of the Department was to revive, extend, and improve the already existing botanic gardens. This action so fostered agricultural development that, at the end of ten years, the Colonial finances had so improved that it was decided to diminish progressively the Imperial grants to the various stations, until in 1912–13 these grants ceased. Sugar production is still a highly important industry; it has been very much improved; the pests and diseases of the sugar-cane are understood, and, what is more important, the growers know how to control the pests; also, the sugar produced by the factories is now a much more valuable product than the old muscovado sugar. The cacao and lime industries have been studied and improved; some minor industries, *e.g.* onion-growing, have also been studied to the advantage of the growers; while encouragement has been given to the production of such crops as maize for home consumption. The latter activity is especially important at the present time, when a wheat shortage is threatened.

A Simple Viscometer.

PARTICULARS of a remarkably simple viscometer devised by Mr. A. G. M. Michell, of Melbourne, are given in *Engineering* for April 16. The instrument is intended for workshop use, and gives rapid determinations of viscosity in absolute measure without requiring extraordinary care or skill. It consists of a cup fitted with a handle and a ball of the same curvature as the cup. Contact of these surfaces is prevented by three symmetrically disposed projections in the cup, raised a mil or two above its surface. The cup is held by its handle, and a few drops of the oil to be tested are placed in it. The ball is then placed in the cup and pressed firmly into it for five or ten seconds. This drives some of the oil out, which collects in a channel; enough oil must be provided in the first instance to ensure that the channel is filled. The instrument is then inverted, and the time taken for the ball to drop clear noted. This time in seconds divided by the constant of the instrument is equal to the absolute viscosity of the oil. The action depends upon the rate at which the oil-film between the cup and the ball thickens under the force of gravity exerted by the ball. This flow of oil is resisted by its viscosity, and the time taken for the ball to fall clear is accordingly directly proportional to the viscosity. The above method is sufficiently accurate for workshop use. To obtain accurate results, the ball is placed at the bottom of a vessel containing a considerable quantity of the liquid. The cup is then lowered over the ball, taking care to exclude air. After pressing the two together as before, they are lifted until the ball clears the bottom of the vessel, and the time it takes to drop clear is noted as before. Mr. W. Ramsay, of Messrs. Cammell and Laird, has made as many as 120 most concordant readings in two hours, and the results plotted quite regularly. With liquids of very low viscosity, the ball is suspended from the arm of a balance. By adjusting the weights, the force tending to separate the ball from the cup can be diminished to, say, one-twentieth of the normal. This increases twentyfold the time needed to effect the separation. The manufacture in this country has been undertaken by Messrs. Michell Bearings, Ltd., 3 Central Buildings, London, S.W.1.

The Chemical Society and its New By-laws.

IT is not surprising in these days, when the old political order has been challenged in so many quarters, that even the scientific societies should be moved to recast their constitution and government in a democratic sense. The Chemical Society is the latest to complete this process of revision, and a record of the chief points in which changes have been made is of public interest.

As a preliminary to any fundamental alterations, a supplemental charter was found to be necessary. The original charter of 1848 included many hampering restrictions, prescribing, for example, the maximum size of the council and the manner of its election. Such provisions, devised for the conduct of a small society associated mainly with London and the immediate districts, are quite unsuitable now that the society numbers more than 3500 fellows, and when probably about two-thirds of these reside beyond the metropolitan area.

There has been some doubt also whether, under the original charter, it was permissible to elect women as fellows of the society. Uncertainty on this point has now been removed by the supplemental charter, which provides that fellows may be of either sex.

Another important feature of the new by-laws based on the supplemental charter is the attempt to secure for provincial fellows a greater share in the conduct of the society. Hitherto every important matter affecting the society, including the election of officers and council, has been determined at a general meeting by a majority of the fellows present and voting. Under the supplemental charter the society has power to elect the officers and council by a postal vote, and further, in certain cases, to take a poll of all fellows resident in the United Kingdom. These powers have been incorporated in the new by-laws.

Another important aspect of these is that there has been kept in view the contingency of combined action with kindred societies concerned in the development of chemical science, as, for example, in the possible acquisition of common premises, or in the publication of joint abstracts. Under the new provisions there will be greater liberty to deal with such a situation if and when it arises, and it may be that these particular modifications of the by-laws will prove to be amongst the most important that have been made.

University and Educational Intelligence.

CAMBRIDGE.—The syndicate appointed to consider the relation of women students to the University has presented a double report. One-half of its members are in favour of admitting women to full membership of the University with a few limitations affecting special posts. They specifically exclude in their proposed statute the recognition by the University of women students at the men's colleges, but they throw open University lectures, examinations, degrees, offices, and emoluments to women on the same terms as to men. The legislation they propose will give degrees to past students of Girton and Newnham.

The report of the second half of the syndicate contains a long discussion of the question. Their actual proposal boils down, however, to a recommendation that the Senate should express itself in favour of a new university being formed from Girton and Newnham Colleges, the intention being to preserve for their students the facilities at present extended to them by the University of Cambridge. The advantages accruing to women students under this proposal would be the awarding of degrees and official consultations between the men's and the women's universities on examination schedules. There is a controversy ahead ending in a contest to which the outside voter will doubtless be summoned by both parties.

Sir Geoffrey Butler, Corpus Christi College, has been appointed secretary of the Board of Research Studies; correspondence in connection with students desiring to come to Cambridge to work for the Ph.D. degree should be addressed to him.

Mr. H. F. Gadow has been appointed reader in the morphology of vertebrates; Dr. H. Scott curator in entomology; Mr. G. F. C. Gordon superintendent of the engineering workshops; and Mr. L. G. P. Thring superintendent of the engineering drawing office.

MR. T. HARRISON HUGHES has made the generous gift of 50,000*l.* to the University of Liverpool as a contribution to the appeal for funds.

A PUBLIC lecture on "The Life-movements of Plants" will be delivered at University College, London, by Sir Jagadis C. Bose on Monday, May 17, at 5.30.

A HOLIDAY course in geology will be held at the School of Metalliferous Mining, Camborne, Cornwall, from July 12 to August 23. The course will consist of lectures, laboratory work, and field work, and occupy five days a week. The lectures will deal with the geology of West Cornwall, with special reference to the economic side.

A LIMITED number of free places, tenable at the Imperial College of Science and Technology, South Kensington, are being offered by the London County Council to candidates who can show that they are qualified to enter on the fourth, or post-graduate, year of the course of study selected. Applications must be made upon Form T2/255 A., obtainable from the Education Officer, L.C.C., Victoria Embankment, W.C., and sent in by, at latest, June 5.

THE council of the London (Royal Free Hospital) School of Medicine for Women will award, in June next, the Dr. Edith Pechey Phipson post-graduate scholarship of the annual value of 100*l.* and tenable for three years. The scholarship is open to all medical women, preferably coming from India or going to work there, for assistance in post-graduate work. Applications are receivable by the warden and secretary of the school, 8 Hunter Street, Brunswick Square, until May 31.

DURING the period immediately following the Armistice it was necessary to adopt temporary measures to fill vacancies in Civil Departments otherwise than by open competitive written examination. The scheme, authorised by Order in Council and under regulations of the Civil Service Commission, has been known as the Reconstruction Scheme. Under that scheme, men who have served in his Majesty's Forces have been chosen to fill positions in the Civil Service by interview before a selection board, following a qualifying examination. The scheme, which has been applied to the Home Civil Service (Class I.), the Indian Civil Service, the Colonial Civil Service, junior or intermediate appointments, and officerships of Customs and Excise, is now coming to an end; and the Civil Service Commissioners announce that the last day for the receipt of applications under it (which must be on the prescribed form) is June 30, 1920, and that *no application received after that date can be considered.* This announcement does not apply to appointments in the Foreign Office and Diplomatic Service or in the Consular Service, which it is intended to make on the Reconstruction Scheme until the end of the year 1921.

THE various associations of teachers in Lancashire and Cheshire engaged in different spheres and branches of education, ranging from the Private Schools Association to the Universities of Liverpool and Manchester, and including all grades and phases of education, have formed themselves into a federal council comprised of two or more representatives from each association or branch with the purpose of considering the further co-ordination of education in Lancashire and Cheshire, and of bringing into closer association teachers who are engaged in different branches of educational work. The council comprises thirty-two representatives, with Principal J. C. M. Garnett as chairman, from fourteen different teachers' associations, and the federal council thus constituted met in Manchester on October 26, 1918. At a later meeting the council appointed special committees to investigate the following matters:—(*a*) The inter-relation of the various types of schools and the age of transfer, together with a national scholarship system; (*b*) the curricula of the several types of schools; (*c*) the training and supply of teachers; and (*d*) the means and methods whereby teachers may secure a more effective voice in the administrative control of education. The recommendations of these committees are set forth in a statement of some seventy pages, published at 1s. by the Manchester University Press, entitled "A National System of Education: Some Recommendations for Establishing it in England during the Decade Ending Ten Years Hence." The statement includes an introduction, being a lecture delivered by Principal Garnett in January last, which is accompanied by an elaborate coloured diagram setting forth the various grades of education for different classes of children according to their opportunities and capacities and their probable future in life. The pamphlet describes nine types of educational institutions and sixteen different types of education, but whether these could not with much advantage be seriously reduced in number is a matter for the grave consideration of educators. It is suggested that there should be established upon the lines of this federal council a provincial joint committee for each of some eight or ten provinces into which England and Wales should be divided for the purposes of education.

Societies and Academies.

LONDON.

Royal Society, April 29.—Sir J. J. Thomson, president, in the chair.—Prof. J. W. **Gregory**: The Irish eskers. Eskers are banks of sand and gravel, typically occurring as ridges on the central plain of Ireland, where they were deposited during the recession of the ice at the close of the Glacial period. They have been generally attributed to deposition along glacial rivers, like Swedish *osar*. Their structure and composition indicate that the most important Irish eskers were formed along the margin of the receding ice-sheets by floods of water, due to the melting of the ice. Irish eskers formed along glacial rivers are relatively small and exceptional. The accumulation of the materials into ridges, and their restriction between about 150 ft. and 300 ft. above sea-level, are attributed to the formation of the eskers where the ice entered into a sheet of water, which was probably the sea, since marine fossils are widely distributed in the adjacent drifts, and there are no embankments to maintain glacial lakes at the required level. It is proposed that the term "esker" should be continued for Irish ridges and mounds of sand and gravel, but that in glacial geology the term "*osar*" should be used for ridges formed along the course of glacial rivers, and "*kame*" for ridges deposited by water along the margin of an ice-sheet.—Miss K. M. **Curtis**: The life-history and cytology of *Synchytrium endobioticum* (Schilb.), Perc., the cause of wart disease in potato. The life-history and cytology of the organism have been followed through all their stages. In the course of the investigation the following important points have been determined: (1) A sexual process has been discovered and followed in all its details; (2) the nature of the difference between the resting (or winter) sporangia and the sori (or summer sporangia) has been established; (3) the infection of the host-tissue by the zoospores and zygotes has been traced; and (4) the peculiarities in the behaviour of the nucleus of the parasite have been investigated.—B. **Sahni**: The structure and affinities of *Acmopyle pancheri*, Pilger. Acmopyle, a monotypic New Caledonian Podocarp, is the most specialised member of the Podocarpineæ, and closely allied to the genus Podocarpus, which it resembles in the vegetative anatomy, drupaceous seed, megaspore membrane, young embryo, structure of male cone, microsporophyll, pollen-grain, and probably male gametophyte. It differs from Podocarpus in (1) the nearly erect seed; (2) the complete fusion of the epimatium to the integument, even in the region of the micropyle, in the formation of which it takes part; and (3) the much greater development of the vascular system of the seed, which forms a nearly continuous cup-like tracheal investment covering the basal two-thirds of the stone. (*a*) The Taxineæ are structurally so distinct from the remaining conifers as to justify their being placed in a separate phylum, Taxales, equivalent in rank, and related to, the Ginkgoales and the Coniferales as here defined. The Cordaitalean affinities of the Taxales are emphasised. (*b*) Concerning the ovuliferous scale of the conifers, the conclusion is in favour of the brachyblast theory, support for this view being derived from the structure of the megastrobilus of Acmopyle. (*c*) No definite opinion is expressed on the question whether the conifers arose ultimately from microphyllous or megaphyllous ancestors, for the origin of the Cordaitales themselves is still regarded as *sub judice*.

Zoological Society, April 27.—Dr. A. Smith Woodward, vice-president, in the chair.—F. F. **Laidlaw**: Contributions to a study of the dragon-fly fauna of Borneo. Part iv.: A list of the species known to occur in the island.—Dr. R. **Broom**: Some new Therocephalian reptiles from the Karroo beds of South Africa.

MANCHESTER.

Literary and Philosophical Society, March 16.—Mr. William Thomson, vice-president, in the chair.—Prof. R. **Robinson**: Note on the mechanism of the production of kynurenic acid in the dog. The formation of kynurenic acid from tryptophane is susceptible of a very simple representation involving normal reactions. The process appears to be primarily one of oxidation followed by decomposition of a carbamic acid derivative, and a probably spontaneous closing of the quinoline ring.—Prof. A. **Lapworth**: Latent polarities of atoms and mechanism of reaction, with special reference to carbonyl compounds. A consideration of the properties of carbonyl compounds shows that divalent oxygen and tervalent nitrogen tend to cause a latent polarisation in the molecules of carbon compounds. When this occurs in a molecule, the other atoms in the neighbourhood show induced latent polarities which the writer indicates by attaching − and + signs to the atoms in alternating order, beginning with the "key atoms," arriving at schemes like those adopted by Fry and others. The induced polarity of an atom or group is not interpreted as necessarily signifying an electric charge, but only as an enhanced or diminished tendency to attract or repel other atoms (or electrons) with definite polar character, and that only at the moment of chemical change (or ionisation, when this occurs). A condition which appears necessary for the full extension of the inductive effect is the occurrence of double bonds (conjugation?), though it may survive the intervention of two successive single ones. While divalent oxygen and tervalent nitrogen (and especially the former) seem more effective than any other atoms, it would appear that halogen (−), hydrogen (+), and metals (+) can act as "key atoms" to a smaller extent; carbon appears almost indifferent. This principle includes Markownikoff's rule of addition, the rules of substitution in the benzene series, the rules of reaction of saturated and unsaturated ketones, nitriles, and carboxylic acids, as well as of their halogen derivatives. The influence of hydrogen as a "key atom" is perceptible in the cresols, of which the relative acidities can be foreseen from a consideration of the influence of the hydrogen atom in the methyl groups on the latent polarities of the atoms in hydroxyl groups.—Prof. R. **Robinson**: The conjugation of partial valencies. The author deals with the mechanism of chemical processes on the basis of a hypothesis of divisible valency, assuming that activation of molecules is due to a partial dissociation or splitting of valencies, and that only molecules so polarised take part in reactions. This accounts for the well-recognised effect of polar atoms on alternate atoms in a chain, and the theory is extended to include cases such as the addition of hydrogen bromide to allyl bromide, where the conjugation of ethylene linkage and bromine atom is relatively weak. Conjugated decompositions and the problem of molecular rearrangement are dealt with.

PARIS.

Academy of Sciences, April 19.—M. Henri Deslandres in the chair.—G. A. **Boulenger**: The fossil Gavialis of Omo.—A. **Vayssière**: The marine fauna of the western coast of the Gulf of Marseilles.—G. **Julia**: New properties of certain very general classes of integral or meromorphic functions.—W. **Sierpinski**: Functions of the first class.—Fr. **Lange-Nielsen**: A generalisation of Rolle's theorem.—J. **Villey**: Flight at high alti-

tudes. Reply to some criticisms of M. Rateau on an earlier communication.—E. **Brylinski**: The transport of electrical energy to great distances. A mathematical discussion of the properties of a half-wave line.—S. **Posternak**: The variations of the composition of ammonium phosphomolybdate. An account of the variations in the composition of the precipitate produced by the presence of ammonium nitrate or sulphate in the liquid in which the precipitate is formed.—F. **Bourion**: The analysis of commercial chlorobenzenes by distillation. The substances present in the commercial product are benzene, monochlorobenzene, and higher chlorination products boiling at 80° C., 130° C., and 172° C. or above. A scheme for systematic fractional distillation is given, with results for synthetic mixtures. The method is a lengthy one, a single sample requiring three and a half days for analysis.—G. **Mignonac**: The ketimines. Formation by the catalytic reduction of the oximes. The reaction was carried out with nickel (reduced from its oxide at 300° C.) in absolute alcohol at ordinary atmospheric pressure at a temperature of about 16° C. The oxime of *cyclo*hexanone gave N-*cyclo*hexylketimine, a substance not previously isolated, and the corresponding ketimines were isolated from the reduction products of the oximes of acetophenone, propiophenone, benzophenone, and phenyl-α-naphthyl ketone.—Mlle. S. **Veil**: Alloys of oxides. Mixtures of the oxides of chromium and cerium were compressed and heated, and measurements made of the electrical conductivity and magnetisation coefficient of the products. Diagrams are given showing the results for varying proportions of the two oxides.—C. **Matignon** and J. A. **Lecanu**: The reversible oxidation of arsenious acid. From the thermochemical data it should be possible directly to oxidise arsenic trioxide to the pentoxide, and experiments were carried out at temperatures between 400° C. and 450° C., the pressures of the oxygen being 130, 127, and 138 atmospheres. The production of the pentoxide was proved, but the oxidation of the arsenic trioxide was not complete.—Ch. **Gorceix**: The formation of the first ocean.—R. **Souèges**: The embryogeny of the Œnotheraceæ. Development of the embryo in *Oenothera biennis*.—M. **Molliard**: The influence of a small quantity of potassium on the physiological characters of *Sterigmatocystis nigra*. Potassium has a marked specific action on the development of this mould. Deficiency of potassium causes the glucose in the culture fluid to disappear more rapidly than the lævulose; conidia and black pigment do not appear as usual; a golden-yellow pigment appears in the fluid, and a soluble substance stained blue by iodine is formed.—G. **Bertrand**: The conditions which may modify the activity of chloropicrin towards the higher plants. The effects of chloropicrin are nearly proportional to the concentration of the vapour and the time of action. Moisture and light, except direct sunlight, are without influence.—M. **Baudouin**: An anatomical measurement permitting the diagnosis of sex in the human skull.—L. **Boutan**: Comparative yields of pelagic apparatus.—P. **Wintrebert**: The propagation of the undulating movement of the muscles of the skeleton in advanced embryos of *Scylliorhinus canicula* after section or partial resection of the spinal cord.—P. **Portier**: The rabbit deprived of its cæcal appendix regenerates this organ by differentiation of the extremity of the cæcum. When the rabbit's appendix is removed the terminal portion of the cæcum is modified, becomes infiltrated with lymphocytes, and regenerates a new appendix possessing the essential histological and physiological characters of the normal appendix. This is a proof of the important function of this organ in the rabbit.—Ch. **Porcher**: Lacteal retention.—M. **Doyen** and coagulating and hæmolysing action of sodium nucleinate.—P. **Courmont** and A. **Rochaix**: The action of the micro-organisms of sewage effluents purified by the activated-sludge method on albuminoid materials, urea, and nitrates.—E. **Aubel**: The sterilising power of acids.

THURSDAY, MAY 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. P. Graves: Welsh and Irish Folk Song.

ROYAL SOCIETY, at 4.—Election of Fellows.—4.30.—Dr. A. D. Waller: Demonstration of the Apparent "Growth" of Plants (and of Inanimate Materials) and of their Apparent "Contractility."—W. N. F. Woodland: The "Renal Portal" System (Renal Venous Meshwork) and Kidney Excretion in Vertebrata.

LONDON MATHEMATICAL SOCIETY, at 5.—H. W. Richmond: (1) Historical Note on some Canonical Forms quoted by Mr. Wakeford. (2) Historical Note on Cayley's Theorems on the Intersections of Algebraic Curves.—T. Stuart: The Lowest Parametric Solutions of a Dimorph Sextan Equation in the Rational, Irrational, and Complex Fields.—A. E. Jolliffe: The Pascal Lines of a Hexagon.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—S. Evershed: Permanent Magnets in Theory and Practice.

INSTITUTE OF INVENTORS (at Royal Society of Arts), at 7.30.—D. Leechman and Others: Discussion on The Relations of the Inventor to the State.

OPTICAL SOCIETY, at 7.30.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Section) (at 28 Victoria Street), at 8.—W. E. Benbow: The Chemical and Physical Properties of Iron and Steel.

ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8.30.—Annual General Meeting.—Dr. S. A. K. Wilson: Decerebrate Rigidity in Man, and the Occurrence of Tonic Fits.

FRIDAY, MAY 14.

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH. Conference of Research Organisations (at Institution of Civil Engineers), at 3.—Marquess of Crewe: Introductory Address.—Dr. A. W. Crossley: The Relation of Research Associations to Existing Institutions for Research.—J. W. Williamson: The Staffing of Research Associations: Salaries and Superannuation.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY OF LONDON, at 5.—Dr. F. Lloyd Hopwood: Demonstration of Experiments on the Thermionic Properties of Hot Filaments.—G. D. West: A Modified Theory of the Crookes Radiometer.—A. Campbell: The Magnetic Properties of Silicon-Iron (Stalloy) in Alternating Fields of Low Value.—T. Smith: Tracing Rays through an Optical System.

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.30.—Annual General Meeting.
MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.
INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at King's College), at 7.—E. G. Humfress: Electrical Motor Control Devices.—The Meeting will be preceded by the Annual General Meeting.
JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—Hon. H. Fletcher Moulton and Others: Discussion on The Business Aspect of the Peace Treaty.
SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.1), at 8.30.—Dr. E. J. Wood: A Consideration of Pellagra from the Standpoint of a "Deficiency Disease."
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. Karl Pearson: Sidelights on the Evolution of Man.

SATURDAY, MAY 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Frederic Harrison: A Philosophical Synthesis as proposed by Auguste Comte.

MONDAY, MAY 17.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Bishop G. Forrest Browne: Monumental Art in Early England, Caledonia, and Ireland.
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—B. J. Lubschez: The Two Great Railway Stations of New York.
ROYAL SOCIETY OF ARTS, at 8.—A. T. Bolton: The Decoration and Architecture of Robert Adam and Sir John Soane, 1758-1837 (Cantor Lectures).
ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Capt. F. Kingdon Ward: The Valleys of Kham.

TUESDAY, MAY 18.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology: The Invaders of England.
ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting.
ROYAL STATISTICAL SOCIETY, at 5.15.—Y. B. Guild: Variations in the Numbers of Livestock and in the Production of Meat in the United Kingdom during the War.
INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—R. Stirling: Air Lift System of Pumping Oil Wells.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Lantern Meeting), at 7.—A. C. Vowles: Wanderings in Mesopotamia (Babylon).
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Sir Henry Howorth: Buddhism in the Pacific.

WEDNESDAY, MAY 19.

SOCIETY OF GLASS TECHNOLOGY (at Institute of Chemistry), at 2.—C. J. Peddle and Others: Discussion on The Physical Properties of Glass.—C. J. Peddle: The Development of Various Types of Glass. Part i.: The Interaction of Silica with the Oxides of Sodium and Potassium. Part ii.: The Interaction of Silica, Lime, and Sodium Oxide. Part iii.: The Interaction of Silica, Lime, and Potassium Oxide. Part iv.: The Interaction of Silica, Lime, and the Oxides of Sodium and Potassium. Part v.: A Comparison of the Soda-Lime-Silica and the Potash-Lime-Silica Glasses.—Dr. M. W. Travers: A Surface Effect in Glass, Probably Caused by Re-heating.—S. English and Dr. W. E. S. Turner: The Thermal Expansion of Magnesia-containing Glasses.—J. R. Clarke and Dr. W. E. S. Turner: The Optical Properties of Some Lime-Soda Glasses.—S. English and Dr. W. E. S. Turner: The Annealing Temperatures of Soda-Lime and Soda-Magnesia Glasses.—J. D. Cauwood, J. R. Clarke, Miss C. M. M. Muirhead, and Dr. W. E. S. Turner: The Durability of Lime-Soda Glasses.—J. R. Clarke and Dr. W. E. S. Turner: The Influence of Lime on the Value of Young's Modulus of Elasticity for the Lime-Soda Glasses.—S. English and Dr. W. E. S. Turner: The Density of Soda-Magnesia Glasses and a Comparison with that of the Soda-Lime Glasses.
ROYAL SOCIETY OF ARTS, at 4.30.—J. S. Highfield, Dr. W. R. Ormandy, and D. Northall-Laurie: The Commercial Applications of Electrical Osmosis.
ROYAL SOCIETY OF MEDICINE (History of Medicine Section), at 5.—Annual General Meeting.—Dr. Withington: The Medical Terms in Liddell and Scott.
ROYAL METEOROLOGICAL SOCIETY, at 5.—Dr. Griffith Taylor: Agricultural Climatology of Australia.—J. E. Clark and H. B. Adames: Report on the Phenological Observations for 1919.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. H. H. Thomas: Certain Xenolithic Tertiary Minor Intrusions in the Island of Mull (Argyllshire).
ROYAL MICROSCOPICAL SOCIETY, at 8.—Annual Exhibition of Microscopic Pond Life.

THURSDAY, MAY 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—A. P. Graves: Welsh and Irish Folk Song.
ROYAL SOCIETY, at 4.30.—*Probable Papers*.—Prof. J. N. Collie: Some Notes on Krypton and Xenon.—Sih Ling Ting: Experiments on Electron Emission from Hot Bodies, with a Preface by Prof. O. W. Richardson.—Dr. L. Silberstein: The Aspherical Nucleus Theory Applied to the Balmer Series of Hydrogen.—Dr. T. E. Stanton, Miss D. Marshall, and Mrs. C. N. Bryant: The Conditions at the Boundary of a Fluid in Turbulent Motion.
ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Brig.-Gen. Lord Montagu of Beaulieu: Roads and Transport in India.
ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.—Annual General Meeting.
INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—G. Rigg: Roasting and Lead-Smelting Practice at the Port Pirie (S.A.) Plant of the Broken Hill Associated Smelters Proprietary, Ltd.—Capt. H. Tatham: Tunnelling in the Sand Dunes of the Belgian Coast.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 5.30 (Annual General Meeting).
OPTICAL SOCIETY, at 7.30.—B. K. Johnson: The No. 7 Dial Sight, Mk. II.—Lt.-Col. Gifford: A Short High-Power Telescope.
CHEMICAL SOCIETY (Ordinary and Informal Meeting), at 8.

FRIDAY, MAY 21.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 5.—Annual General Meeting.
WIRELESS SOCIETY OF LONDON (at Institution of Civil Engineers), at 6.—P. Coursey: Some Methods of Eliminating Atmospherics in Wireless Reception.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Annual General Meeting.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. J. A. Fleming: The Thermionic Valve in Wireless Telegraphy and Telephony.

SATURDAY, MAY 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Frederic Harrison: The Re-action and the Critics of the Positivist School of Thought.

The Officers Training Corps and the Universities.

IN a leading article on "The Universities and the Army," in NATURE for April 8, we referred to the Memorandum on the Army Estimates for 1920–21 published by the War Office, and quoted the words: "One of the important lessons of the war has been the extent to which the Army is dependent on the Universities." Of these lessons one especially was emphasised, viz. the necessity for the reorganisation of the Army on its educational side. We were told again and again, both during and after hostilities, that the war was primarily a scientific war—laboratory against laboratory, machine shop against machine shop, trained intelligence against trained intelligence—and it is gratifying to know that the War Office recognises that "the Universities responded to the call for help in a splendid manner." That they did so is an indisputable fact. Thousands of undergraduates and hundreds of their teachers, from junior assistant to full-fledged professor, switched off from classics, history, philosophy, natural science, and what not, to gunnery, engineering, motor transport, and so on. Chemical laboratories substituted investigations on explosives, anti-gas protectives, and smoke screens for routine qualitative and quantitative analysis; engineering laboratories concentrated their energies on the invention of depth charges, shell-gauges, and submarine engines; and the geologist relinquished the study of stratigraphy and palæontology to discover new sources of sand from which to manufacture glass. All this work was novel to the Universities, and, as many would add, foreign to their purpose and traditions; yet should another war of similar magnitude ever arise, can it be doubted that the Universities will again be called upon to play an even greater part in it than they did in the Great War of 1914–18?

If this be so, and if the Army be regarded as a profession, should its officers not receive a professional training, and where more appropriately and effectively than in the Universities? One of the most enlightened features of Army reorganisation introduced by Lord Haldane in 1907 was the institution of the Officers Training Corps in connection with the Universities. Had this tentative scheme of professional training for future Army officers received proper encouragement and been developed on suitable and elastic lines, the War Office might have had at its disposal in the autumn of 1914 a large reserve of trained officers who had passed through a properly devised University curriculum.

The military education committees of the various British universities and university colleges were recently sounded as to their views on the future of the Officers Training Corps, and from the replies received it would appear that most of them are unwilling to commit themselves to any plan of action until the attitude of the Army Council in reference to the Corps has been ascertained. What that attitude may be we have at present no means of finding out. We are informed that one of the largest Universities in the Kingdom answered the inquiry in the following terms: "The Military Education Committee are not of the opinion that it is desirable to take any further action at the present time until the Army Council have made a definite statement with regard to the future position of the Officers Training Corps, or to take any steps in regard to the creation of a Department of Military Studies until this official statement is issued." Several other Universities replied in similarly non-committal terms, and out of twelve, only one expressed any enthusiasm on the subject.

If the Army Council sincerely desires to make use of the Universities in the training of officers, let it say so in clear and unmistakable language, and indicate at the same time how and to what extent it is prepared to aid the Universities in carrying out its ideas. Some progress might be made, for example, if the Army Council would appoint a committee representing all departments concerned with Officers Training Corps, *with power to act and not merely to hear and report*, to meet and confer with representatives of the Universities, who on their side could submit the special needs of the Universities regarding Officers Training Corps. We cannot get rid of the suspicion that the War Office authorities are unaware of the work and organisation of the

newer Universities, and that they are still convinced that Great Britain has only two institutions worthy of the title. Have they any adequate conception, for example, of the extent and capacities for teaching and research of the faculties and departments of metallurgy, engineering, chemistry, and applied electricity at Sheffield, Leeds, Manchester, and Liverpool, to mention only one group of provincial Universities, and how it might be possible, in connection with a properly organised training corps, to provide instruction for cadets in those branches of specialised military work for which a particular University had special facilities and equipment, involving the application of science to war?

The Regulations governing the O.T.C. are dated 1912, but we have learnt much since then, and it is essential before these Regulations are revised and re-issued that the Army Council should take the Universities into its confidence, and, in consultation with their representatives, produce a scheme of training that shall conform to University practice and be within the range of University capacity, while at the same time meeting the requirements of the Army Council in its effort to obtain suitably trained men to command the various units of the Army of the future.

Relativity and Geometry.

The Foundations of Einstein's Theory of Gravitation. By Erwin Freundlich. Authorised English translation by Henry L. Brose. Preface by Albert Einstein. Introduction by Prof. H. H. Turner. Pp. xvi+61. (Cambridge: At the University Press, 1920.) Price 5s. net.

PURELY mathematical workers have often found occasion to remark on the prophetic vision of Riemann. He possessed that special genius which catches glimpses of truth, of no special significance to a contemporary, which one day are found to have an importance greater even than the seer himself had dreamed. Certainly this has proved so with much of Riemann's work. His famous *Habilitationsschrift*, "On the Hypotheses which lie at the Bases of Geometry," was presented to the faculty of philosophy at Göttingen in 1854, and, in an English translation by Clifford, was brought to the notice of the British public in the columns of NATURE (vol. viii., Nos. 183–84, pp. 14–17, 36, 37). It may be permissible to quote one or two prophetic phrases:

"It seems that the empirical notions on which the metrical determinations of space are founded, the notion of a solid body and of a ray of light, cease to be valid for the infinitely small. We are therefore quite at liberty to suppose that the metric relations of space in the infinitel[illegible] do not conform to the hypo[illegible]y; and we ought in fact to suppose it, i[f] we can thereby obtain a simpler explanation of phenomena."

It is worthy of note that Riemann never speaks of space itself as being non-Euclidean. He carefully refers always to the metric or measured relations. The "ground" of these metric relations is to be sought in the nature of the reality underlying space. Is that reality a discrete manifoldness, or is it continuous? If the latter, then the "ground of the metric relations" must be sought in the properties of that reality, or, as he says, "in binding forces which act upon it." Could anything be more prophetic of Einstein's conception of gravitation? Then, as if to anticipate the conservative and the scoffer of to-day, he continues:

"The answer to these questions can only be got by starting from the conception of phenomena which has hitherto been justified by experience, and which Newton assumed as a foundation, and by making in this conception the successive changes required by facts which it cannot explain. Researches starting from general notions, like the investigation we have just made, can only be useful in preventing this work from being hampered by too narrow views, and progress in knowledge of the interdependence of things from being checked by traditional prejudices."

With this open mind, and the work of Gauss, Lobatchevsky, and Bolyai on the geometry of figures on curved surfaces to provoke thought, Riemann faces the possibility that the geometry of three dimensions of actual material bodies may not be so simple as Euclid's system suggests. Geometry in the ordinary sense is, in fact, eliminated; the metrical relations of bodies are "studied in abstract notions of quantity"; the results of calculation may afterwards be expressed in geometric form. Indeed, what is meant by the "length of a line," or a "line element," becomes far from clear from the geometrical point of view. It is merely some quantity which serves to distinguish one point from another. The question is asked: What type of magnitude may be constructed out of the quantities that serve to define two special points in a material body, which may conveniently be taken as a measure of their distinctness one from the other, first from a purely mathematical point of view, but afterwards by an empirical test of its abiding value. Riemann is led to use the general quadratic differential form as the simplest possible expression.

It is easy for one writing now to see the organic connection between Riemann's thought and the step made by Einstein in passing from the special principle of relativity propounded in 1905 to the general theory now established. The recognition of the relative nature of time measurement had already been made in the special principle, and Minkowski quickly perceived that our separate concepts of space and time were thereby brought into a unity. It seems now but a short step to apply Riemann's analysis to this four-dimensional view of the universe.

But questions still linger; the romance of relativity, its sweeping comprehensiveness, leave us breathless. When Dr. Freundlich tells us that "space is banished out of physical laws altogether: just as æther was eliminated out of the laws of electrodynamics by the special theory of relativity," we must pause and ask ourselves if enthusiasm is not going too far. Dr. Freundlich himself finds the mainspring of Einstein's method in two fundamental postulates: (i) that of continuity; (ii) that of causal relationship between only such things as lie within the realm of observation. It was the craving for *continuity* that gave rise to Faraday's conception of tubes of force, developing gradually into the electromagnetic æther. It is the instinctive faith in the second postulate that leads the timid to distrust the formidable array of differential equations between an army of variables that represent the gravitational field in Einstein's theory.

No physical theory has the power to forbid the mind to use the firm scaffolding of Euclidean truth on which to build its own representation of the universe. True, it may be that the representation is not so simple as we had thought; that the Euclidean element of length does not correspond exactly to a measured interval in a rigid body. But the work of the exponents of relativity is not finished until an added clearness is given by them to the picture of how natural phenomena are related. The æther must not be put on the scrap-heap, but must be rehabilitated. Space must not be spoken of as warped, for that is to leave far behind the essential nature of space as a mode of apprehension. The only true continuum is that which the mind conceives. Matter cannot be a singularity in mental space; it can only be a singularity in the picture drawn upon that background. Matter is one and minds are many. So many minds, so many pictures of matter. The correspondences between the pictures are the grounds of our intellectual intercourse, the only evidence of the external world which we possess.

To turn over the pages of this pamphlet is to encounter many questions; nevertheless the reader will have nothing but thanks to offer to the author, and especially to Mr. Brose, who, while yet a prisoner in an enemy country, found solace in truth that transcends racial strife, and translated it for our enjoyment. E. CUNNINGHAM.

Colloidal Therapy.

The Use of Colloids in Health and Disease. By Alfred B. Searle. With foreword by Sir Malcolm Morris. (The Chadwick Library.) Pp. vii+120. (London: Constable and Co., Ltd., 1920.) Price 8s. net.

BASED on a lecture delivered at the request of the Chadwick Trustees, this volume provides in compact form an account of the principal facts which are known at the present time regarding matter in its colloidal form, with special reference to the utilisation of colloids in the normal animal organism and in the treatment of disease.

We find a lucid account of the physical properties of colloidal matter and of its reactions in the presence of ionising currents, of electrolytes, of radiations, etc. There is explained in simple scientific language the colloidal nature of cellular protoplasm and the selective permeability of cell membranes for salts and colloids.

The importance of the relatively high content of the protective colloid, lactalbumin, in human milk in relation to its digestibility is emphasised, and the means are stated by which cow's milk may be rendered more suitable for human consumption. In discussing the colloidal nature of the blood, reference is made to the adsorption theory of the conveyance of blood gases and to the phenomena of hæmolysis; an isotonic saline solution is, however, 0·9 per cent. sodium chloride.

The modern processes for precipitating colloidal matter in sewage and drinking water, and the use of soap as a detergent, are also briefly reviewed. The author suggests that the hygienic effect of sea-air is due to the presence in it of particles positively charged by the beating of the waves on the shore, which particles precipitate negatively charged bacterial and other colloids; and in regard to the invasion of the body by micro-organisms, he considers that disturbance of the normal colloidal condition of the body-cells or fluids by undesirable electrolytes, salts, or colloids of the "opposite" sign is an ætiological factor.

The author has devoted considerable space to accounts of the preparation of colloidal sols and of their use in therapeutics. In the latter respect he has digested the bulk of the recent and rele-

vant medical literature on the colloidal remedies now in the market. The relative value of colloidal drugs in treatment is still *sub judice*, and we can only hope that the author's optimism regarding their effects as therapeutic agents may be justified in the future. In this section we note several misprints, such as "epiditymitis," "granulama pupendi," and "leishmonnoris," to mention only a few, and the assertion that the colloidal state is the ideal one for the administration of alkaloids is contrary to the evidence afforded of the inefficacy of colloidal quinine and cocaine. In the course of the work the author makes many speculations on the *rôle* of colloids in physiology and on their possibilities in treatment, speculations which form food for reflection if one is unable to assimilate them all as truths.

The volume, to which Sir Malcolm Morris, whose pioneer work with colloids in skin diseases is well known, contributes an interesting and hopeful foreword, forms a helpful introduction to the subject of colloids in their relation to physiology, pharmacology, and therapeutics, and may be found useful by medical practitioners and others who desire to have a general and not too scientific account of the subject.

Nature Pictures.

Twenty-four Nature Pictures. By E. J. Detmold. (London: J. M. Dent and Sons, Ltd., n.d.) Price 5 guineas net.

SEVERAL important works have recently been published portraying and describing the birds and mammals of the British Islands. Some of these publications are expensive, others appeal to a slender purse; but, whether the lover of such books is able or willing to spend much or only a little on animal pictures, he is fortunate in having a good deal of scope for choice, many of the works that we have seen of late being excellent in every way, combining artistic merit with scientific accuracy.

In introducing a new work on the higher animals to the British public, therefore, it behoves its author to show that it possesses some outstanding feature of merit which may serve as its *raison d'être*. The work under consideration cannot be regarded as serving any zoological purpose, since the subjects are so few in number. Hence any merit it may lay claim to must be sought from its purely artistic side. But such pictures, to be satisfactory, should be accurate in form and colour, so that, while appealing to the artistic sense, they do not at the same time offend the scientific eye; and herein the nature-studies of Mr. Detmold are decidedly faulty.

In a series of twenty-four plates the artist portrays altogether five species of mammals, twenty birds, a fish, a crab, and a lobster. Zoologically speaking, the two crustaceans are, in our opinion, the most successful portraits in the series. The majority of mammal and bird studies are distinctly disappointing, and lead one to fear that they have been drawn from specimens supplied by some unskilful taxidermist. They seem to lack the subtle and delicate curves of beauty we are accustomed to associate with the living and healthy animal, while in some cases the colouring is faulty. The proportions, too, between the parts of the body are sometimes incorrect, even allowing for the effects of foreshortening. In the painting of plumage and pelage there are a peculiar "lumpiness" of surface and angularity of outline which are foreign to our ideas of animal form and beauty. Whether the artist has allowed himself to be carried away by the licence proverbial to his profession, or is endeavouring to formulate a new style of composition and portraiture, we cannot say, but the effect, at least from a zoological point of view, is disappointing and at times irritating.

The surroundings of the various subjects are certainly artistic and original, but in some plates the environment is overloaded with detail, while in others its artificiality is oppressive, and suggests tapestry or wall-paper rather than a background for a "nature-picture." W. E. C.

Our Bookshelf.

General Science: First Course. By L. Elhuff. Pp. vii + 435. (London: G. G. Harrap and Co., Ltd.) Price 5s. net.

THAT a pupil's first view of science should be a broad one has been more generally recognised in the United States than in this country. The routine of measurements and weighings, which is all that so many of our children know as science, fails to arouse enthusiasm except as a relief from work which is still more dull. Teachers who are breaking away from this system have been helped by more than one recent American publication. Their attention is confidently directed to the volume now under review.

In its general outlines the book does not differ widely from some of the best of its kind, but it is exceptional in that stress is laid in the earliest chapters on the value and the means of maintaining health. To the question "Why study science?" the answer is given: "To learn how to live." That is kept constantly in view throughout the book. In his preface the author puts the following first among the results which he hopes may be achieved: "A desire to grow strong

in body and mind and to remain free from disease. . . . Successful work on the part of many boys and girls is dependent upon this desire becoming strong enough to rule the body." So it is not surprising to read as an exercise to be set to pupils: "Notice what effects tobacco, alcohol, opium, etc., have upon those who use them." But another, "Observe whether tea and coffee affect the health and 'temper' of parents," makes one wonder whether tactless observation might not have even more effect than the stimulants!

Where it follows lines which are already becoming conventional in America the book is good; in the more novel parts it is even better.

A Geographical Bibliography of British Ornithology from the Earliest Times to the End of 1918. By W. H. Mullens, H. Kirke Swann, and Rev. F. C. R. Jourdain. Part 1. Pp. 96. (London: Witherby and Co., 1919.) Price 6s. net.

MESSRS. MULLENS AND SWANN have already made ornithologists their debtors by compiling a "Biographical Bibliography of British Ornithology" (completed in 1917). Of this the present work is a supplement or continuation, the books and articles being now arranged under counties. The Rev. F. C. R. Jourdain has shared the labour. The aim of the authors has been to give an account, as complete as possible, of the literature and records relating to the avifauna of each county. This will be of great value to local workers, and there is good sense in Gilbert White's remark, quoted on the title-page: "Men that undertake only one district are much more likely to advance natural knowledge than those that grasp at more than they can possibly be acquainted with; every kingdom, every province, should have its own *monographer*." The labour of making this bibliography must have been very great; it has extended over six years, and has meant the consultation and analysis of a huge mass of literature. There are to be six parts, and those which have appeared represent arduous and useful work well executed.

The Philosophy of Conflict: and Other Essays in War-Time. By Havelock Ellis. Second series. Pp. 299. (London: Constable and Co., Ltd., 1919.) Price 6s. 6d. net.

MR. ELLIS is likely to find readers for this collection of essays. His social studies turn on sex-problems, often shrewdly handled. His literary and anthropological studies are dominated by his sense of the picturesque. He is arrested by the picture-making metaphors of Conrad, and by the picturesque theories of Sollas in prehistoric anthropology. In his essays in this last group he reminds us of his own portrait of Jung, wandering "with random, untrained steps, throwing out brilliant suggestions here and there." But in the essay in which this portrait occurs he is on his own ground, and justifiably dwells on his part in introducing to English readers the picturesque psychology of Freud.

The Cost of Scientific Publications.

MAY I add a word to this most interesting discussion from the point of view of the society with which I am most concerned?

The London Mathematical Society was founded by De Morgan and others in 1865, and has steadily improved its position until it is admittedly the leading mathematical society in the country. It is a comparatively small society, and its activities are almost entirely concentrated on the publication of its Proceedings, to which purpose practically its whole income is devoted. It has no paid staff of any kind.

Before the war the society was able to publish annually about 500 pages of original research, at a cost of some 300*l*. to 350*l*. Now a volume of 400 pages only, costs some 600*l*., and such slight increase of income as there has been is entirely insufficient to meet the new situation. Most of the members are life-compounders, and it is exceedingly difficult to raise the membership beyond a certain point; it was 290 in 1918, and is now about 340. A committee is considering what is possible in the way of economy or increase of charges, but every increase of charges makes it harder to secure new members, and the only substantial economy possible lies in a further limitation of output.

If the society is to maintain the position won by years of effort before the war, it must at all costs keep up both the quality and the size of its Proceedings. In particular it must continue to attract the best work of young mathematicians; and it cannot do this if it has to hamper them at every turn by incessant demands for condensation. A considerable part of the volumes must always be occupied by the work of men of established reputation, and if they are to be further curtailed it is the younger men who will in the first instance be likely to suffer.

The society has during the last year been able to obtain some aid from the fund under the control of the Royal Society, but it is plain that the demands on the fund are likely to multiply, and all possible pressure should be brought to bear on the proper authorities to augment it.

G. H. HARDY,
Hon. Sec. London Math. Soc.

New College, Oxford, May 15.

IN the leading article in NATURE of May 6 on the cost of scientific publications, reference is made to the critical financial position of those of our scientific societies which have no popular means of adding to their income. The position is serious. The scientific worker, upon whom, to a great extent, a scientific society depends for maintenance, is rarely in a position to add to his financial obligations, and the interested person from whom the society also receives considerable support is often in a similar position. If a society is to be efficient, the library must be kept up, the standard of publications be maintained, and its salaried staff receive at least a living wage. How is this to be done? Apart from external aid, there are only two ways—by exercise of rigid economy, and by increased contributions from the members. It is not economy to starve the library, and economy in publication must be employed with

great discretion. The dignified quarto which supplies a link with the early days of the society may be suspended, illustrations reduced to the absolute minimum, communications condensed or reduced, and every conceivable means adopted to avoid expense; but with a diminished sum available for printing, and printing costs trebled, it is obvious that the efficiency of the society as a means of publication must be seriously reduced.

This result bears heavily on oversea members. The member within reach of town has all the advantages of the society; he can attend the meetings, consult the library, and meet his colleagues at the society's rooms; the country member is less favourably situated, but he has at least the privilege of borrowing from the library. The only material advantage received by the oversea member is the scientific publications of the society. The oversea members are an important part of the society, which, though "of London" in style, is world-wide in interest and membership. Our colleagues oversea, though in many cases supporting their own local society, consider it an honour to belong to the mother society at home, and the aim of the mother society is to strengthen the bond and to show the worker oversea that he is both welcome and necessary. Any step, therefore, which tends to lessen the advantages reaped by the oversea member must be avoided.

Apart from external aid there remains only the increased contribution from the individual member. An increase in the subscription will fall hard on many members; but the claims of a society which represents one's work or the scientific interest of one's leisure will not easily be set aside. A man or woman does not join a scientific society in a commercial spirit, but because a congenial atmosphere is there found, or, in the highest motive, because it is an obligation and an honour to help forward the society which represents one's own branch of science. If each member will consider seriously the position of his society, the claim for external aid, amply justified by the value to the community of the scientific work of the society, will come with increased power.

A. B. RENDLE.

THE leading article in NATURE of May 6 has so admirably stated the case for assistance towards the publications of scientific societies that it is almost needless to add further arguments. Nevertheless, there is one point which seems to require attention, namely, that during the last two years, when the pressure of enhanced prices in the printing trade has made itself felt, there has been an attempt on the part of societies subject to this burden to palliate it by means which threaten to change the character of the meetings. To avoid the heavy cost of papers embodying recent research, there has developed a marked tendency to arrange for lectures and demonstrations of a kind which do not require publication in detail, to the disadvantage of original memoirs which demand illustration and extensive text. Should this procedure continue, it is plain that research will suffer, investigators will not be ready to produce the results of their work in the meetings, and the value of the societies' issues will be diminished.

If assistance of the kind advocated can be secured, former methods can be resumed; if that assistance is denied, it is to be feared that, in spite of stringent economy or increased subscriptions on the part of the societies, the publications will suffer; for the maintenance charges must first be met before the balance of income is available for printing memoirs.

B. DAYDON JACKSON.

I DO not suppose that there is a single editor of a scientific journal who will not read with sympathy and gratitude of your effort to obtain financial support for such publications in view of the enormously increased cost of paper and printing. In the case of the *British Journal of Psychology,* with which I am specially connected, the subscription is being raised for the second time since the war, whilst no class has suffered more as regards income than that from which the subscribers to scientific journals are drawn.

CHARLES S. MYERS.

30 Montagu Square, W.1, May 10.

The Indian Chemical Service.

SIR P. C. RÂY's objections to the proposal to form an Indian Chemical Service are based upon the fact that the Education Department of India has failed to realise the importance of research in connection with university teaching. However, I feel sure that he would not advocate the abolition of that Department, much less would he wish to see the Indian Education Service a mere adjunct to some other branch of the public services, without even provincial directors to look after the interests of himself and his colleagues. Every member of a Service knows that, in the event of a difference arising between himself and a member of another Service, he will have the support of a senior member of his own Service at each stage until the matter is perhaps settled by the Viceroy himself. Even directors-general and members of council are human, and inclined to support members of their own Department against the world.

Prof. Thorpe does not dwell at any length on the personal aspect of the problem, but I gather from his letter that he appreciates the importance of it. I do not doubt that he has grasped the fact that, while the members of such units as the Geological Survey of India or the Indian Medical Service are contented with the conditions of their service, grave discontent prevails amongst the numerous scientific men attached to, but not members of, organised Services. The fact that many men holding such positions have thrown up their appointments and come home disgusted has added considerably to the difficulty in recruiting scientific men, and particularly chemists, for service in India. There is no alternative to the bureaucratic system of government for India, and the proposed scheme provides for its inherent defects.

It is, of course, essential that the director-general and the directors of provincial institutes should be chemists who have proved their capacity for research. The Geological, Botanical, and Zoological Surveys of India seem to get on fairly well under directors-general who are scientific experts, and I do not see the necessity for assuming that the head and sub-heads of the Chemical Service will be any less competent than those who have done distinguished service for India in other branches of science.

Knowing something of India, I believe that the proposed scheme is sound, and I wish it every success.

M. W. TRAVERS.

A New Method for Approximate Evaluation of Definite Integrals between Finite Limits.

1. If $f(x) = a + bx + cx^2 + dx^3 + gx^4 + hx^5 + jx^6 + kx^7 + lx^8 + mx^9$, the value of $\frac{1}{4}[f(\frac{1}{10}) + f(\frac{4}{10}) + f(\frac{6}{10}) + f(\frac{9}{10})]$ is

$$a + 0{\cdot}5000b + 0{\cdot}3350c + 0{\cdot}2525d + 0{\cdot}2028g + 0{\cdot}1696h + 0{\cdot}1455j + 0{\cdot}1270k + 0{\cdot}1120l + 0{\cdot}0994m$$

which is approximately identical with

$$a+0{\cdot}5000b+0{\cdot}3333c+0{\cdot}2500d+0{\cdot}2000g+0{\cdot}1667h+0{\cdot}1429j+0{\cdot}1250k+0{\cdot}1111l+0{\cdot}1000m,$$

that is, with

$$a+\tfrac{1}{2}b+\tfrac{1}{3}c+\tfrac{1}{4}d+\tfrac{1}{5}g+\tfrac{1}{6}h+\tfrac{1}{7}j+\tfrac{1}{8}k+\tfrac{1}{9}l+\tfrac{1}{10}m,$$

which is $\int_0^1 f(x)dx$.

An approximate evaluation of $\int_0^1 F(x)dx$ is therefore given by

$$\tfrac{1}{4}[F(\tfrac{1}{10})+F(\tfrac{4}{10})+F(\tfrac{6}{10})+F(\tfrac{9}{10})].$$

2. The following table shows for several functions the value of the integral and the approximate evaluation by this four-ordinate rule and by two *seven*-ordinate rules in common use, viz. :—

Simpson's rule :—

$$\int_0^1 F(x)dx=\tfrac{1}{18}[F(\tfrac{0}{6})+F(\tfrac{6}{6})+2\{F(\tfrac{2}{6})+F(\tfrac{4}{6})\}+4\{F(\tfrac{1}{6})+F(\tfrac{3}{6})+F(\tfrac{5}{6})\}],\text{ approx.}$$

Weddle's rule :—

$$\int_0^1 F(x)dx=\tfrac{1}{20}[F(\tfrac{0}{6})+5F(\tfrac{1}{6})+F(\tfrac{2}{6})+6F(\tfrac{3}{6})+F(\tfrac{4}{6})+5F(\tfrac{5}{6})+F(\tfrac{6}{6})],\text{ approx.}$$

$F(x)$	$\int_0^1 F(x)dx$	New rule	Simpson	Weddle
Semicircle $(x-x^2)^{\frac{1}{2}}$	$\frac{\pi}{8}=0{\cdot}3927$	0·3949	0·3815	0·3835
Quadrant $(1-x^2)^{\frac{1}{2}}$	$\frac{\pi}{4}=0{\cdot}7854$	0·7868	0·7775	0·7789
$(4x-x^2)^{\frac{1}{2}}$	$\frac{2}{3}\pi-\frac{\sqrt{3}}{2}=1{\cdot}228$	1·231	1·217	1·219
$\log(1+x)$	$2\log 2-1=0{\cdot}3863$	0·3859	0·3863	0·3863
e^x	$e-1=1{\cdot}718$	1·720	1·718	1·718
$\frac{1}{1+x}$	$\log 2=0{\cdot}6931$	0·6937	0·6932	0·6931
$\frac{1}{2+x}$	$\log\frac{3}{2}=0{\cdot}4055$	0·4056	0·4055	0·4055
$\sin x$	$1-\cos\frac{180^\circ}{\pi}=0{\cdot}4597$	0·4593	0·4597	0·4597

3. The approximation is convenient for the practical determination of the area of a closed curve, such as an indicator diagram. The arithmetical mean of the ordinates at one-tenth, four-tenths, six-tenths, and nine-tenths of the range is the mean ordinate for the range.

The decimal division of the range, the use of only four ordinates, the extremely simple arithmetic involved, and the degree of accuracy attained should make the rule of practical value.

A. F. DUFTON.

Trinity College, Cambridge,
April 30.

British and Metric Systems of Weights and Measures.

ARE not those who discuss the relative claims of 4 mils and 5 mils as the substitute for the penny in a decimal division of the pound merely trying to minimise the disadvantages of what must in any case be a change for the worse? It seems that the advantage of any given system of weights or measures lies largely in the facilities that it offers for the division of a sum or quantity into equal parts. In this respect any decimal system is deficient by the absence of the factor 3, and by the frequency of the factor 5, which is of much less use than 4 for practical purposes. The *reductio ad absurdum* of the metric system seemed to be reached in the issue in Portugal some years ago of a $2\frac{1}{2}$ reis postage stamp (they now call it $\frac{1}{4}$-cent). A rei is one-thousandth part of a milrei or dollar, about equal to one-twentieth of a penny—surely a small enough unit for any purpose, and yet it is found necessary to halve it!

The following comparison seems instructive :—

No. of farthings in one pound $=960=2^6\times3\times5$.
This has 11 factors between 1 and 20,
20 factors between 1 and 100.
No. of inches in one mile $=63{,}360=2^7\times3^2\times5\times11$.
This has 14 factors between 1 and 20,
34 factors between 1 and 100.
No. of ounces in one ton $=35{,}840=2^{10}\times5\times7$.
This has 9 factors between 1 and 20,
17 factors between 1 and 100.
No. of grains in one lb. troy $=5760=2^7\times3^2\times5$.
This has 13 factors between 1 and 20,
26 factors between 1 and 100.
No. of seconds in one day $=86{,}400=2^7\times3^3\times5^2$.
This has 13 factors between 1 and 20,
32 factors between 1 and 100.

Contrast with these :—

No. of millimetres in one kilometre, or of grammes in one metric tonne $=1{,}000{,}000=2^6\times5^6$,
which has only 7 factors between 1 and 20,
14 factors between 1 and 100.

If all the above five English systems be taken together, it will be found that :—

The factor 2	occurs	37 times
,, ,, 4	,,	17 ,,
,, ,, 8	,,	11 ,,
The factors 3, 6, and 12	occur	8 ,,
,, ,, 5, 10, 16, and 20	,,	6 ,,
The factor 15	occurs	5 ,,
The factors 9 and 18	occur	3 ,,
And the factors 7, 11, and 14	,,	once each.

Now, though it cannot be contended that the man who wants to divide 100*l.* into seven parts is helped by the fact that there are 28 lb. in a quarter, or he who would divide a ton into eleven parts by the number of yards in a furlong, yet it seems worthy of note that in our admittedly heterogeneous system all the numbers below 20, except 13, 17, and 19, should be represented as factors, and that to an extent so nearly proportional to their probable utility.

M. E. YEATMAN.

Parliament Mansions, May 7.

Scientific Apparatus and Laboratory Fittings.

I AM surprised to see that Prof. W. M. Bayliss, who writes in NATURE of May 6 on the proposed Anti-Dumping Bill, has misunderstood the Bill so far as it relates to scientific instruments. This Bill does not propose a tariff, but prohibition, except under licence.

The British Optical Instrument Manufacturers' Association has urged the Government to act by prohibition except under licence rather than by tariff, and this is what the Bill proposes. It has always considered that the effect of a tariff might, as Prof. Bayliss suggests, give "no inducement to the makers to improve the quality"; and it has urged that licences should always be freely granted where articles were not being made in the required quantity or up to the standard of quality of goods that could be imported from abroad.

Prof. Bayliss's desire for "free import of such apparatus *until* equally good material is to be had cheaply at home" is provided for by the Bill with the exception of the one word "cheaply," and I suggest that he has, perhaps unintentionally, given the impression that a tariff on goods which either are not or cannot be made in this country has been proposed.

The whole question appears to be: Are scientific men prepared to pay more for British-made scientific instruments of approved quality to meet higher wages or the depreciation of foreign currency rather than have the whole industry extinguished in this country?

With the mark at something like one-tenth its pre-war value, it is obvious that no instrument can be produced in this country to compete as regards price with those made in Germany. The Government, through the British Scientific Instrument Research Association, is giving State aid as regards perfecting processes. Sir Herbert Jackson (who is director of the association) is already producing most valuable results; but if financial considerations make it impossible to sell the articles so produced, it does not meet the case.

Quite apart from the danger to the State which will ensue in case of another war if the scientific industry does not exist, surely it must be evident that science cannot develop properly in any country that cannot produce at least the majority of its own scientific instruments.

A much closer combination between scientific and practical men than existed before the war is required. It has already commenced, and I desire to take this opportunity of explaining that the association of which I am president has a technical committee the members of which place their services at the disposal of the scientific world to discuss all questions the solution of which depends on the production or development of scientific instruments.

Conrad Beck,
President of the British Optical Instrument Manufacturers' Association.
2–3 Duke Street, St. James's, Westminster, S.W.1, May 10.

Prof. Bayliss's letter in Nature of May 6 raises a subject which is of the greatest interest to manufacturers, as well as to users of all classes of scientific apparatus. We do not think that anyone will dispute the contention that scientific workers should have the very best apparatus which is available, and wherever British apparatus is not up to the standard of foreign competitors there is no doubt that the importation of the foreign articles should be allowed. It is, however, quite a different matter when orders are placed by scientific workers, hospitals, etc., with foreign firms on account of the latter being able to quote lower prices than the English manufacturers can do at the present time.

It has recently come to our knowledge that an important hospital supported chiefly by voluntary contributions has placed a large order for X-ray equipment abroad on account of the lower price quoted, not because the staff was of the opinion that better apparatus could be obtained from this source, as, in fact, we were definitely assured that, except for price, our models were preferred. We would ask the committee which was responsible for placing that order whether it had carefully considered the effect of its act, especially should it be repeated to any considerable extent. It is generally acknowledged that, prior to the war, the British manufacturers were not giving to the medical world the very best service, and both medical men and manufacturers have often asked the reason why. It is too large a question to go into the fundamental reasons, and opinion would no doubt differ as to these; but there is no doubt that in the year 1914 there did not exist a sufficient demand for British X-ray apparatus to allow manufacturers to work on a large enough scale to ensure satisfactory service and economical production. During the war the cutting off of foreign supplies and the increased demand for apparatus enabled the firms concerned to venture on a bolder policy, until by the end of the war there were established in the country adequate manufacturing facilities. After the armistice the Government orders dropped to zero, but the demands for up-to-date equipment from private hospitals, and from foreign quarters which had been starved during the war, were sufficient to fill the gap and to enable various firms to carry on their manufacturing programme without undue alarm for the immediate future.

The past year has been one of great difficulty in the manufacturing world, and, with the publication and issuing of catalogues and price lists scarcely yet complete, a great deal of the heart will be taken out of British manufacturers if they find that, owing to a circumstance over which they have no control, they are going to lose a large part of their home trade. The circumstance to which we refer is that of the rate of foreign exchange, against which tariffs, unless extremely heavy, are of no value whatsoever. It is very difficult to obtain trustworthy information as to the prices at which German and Austrian goods can really be delivered in this country, but in one specific instance we ourselves are being offered one of our staple articles of manufacture at a price which is very considerably below the actual cost of the raw material which we use in the manufacture. Prior to the war the articles were not made in this country at all, and it was only by the employment of considerable research and a heavy initial expenditure that their production was assured and perfected. We do not think that some scientific workers, medical men, and others quite realise that under present conditions high prices are essential in connection with scientific apparatus as with all other commodities, and that if they wish to obtain really good service from British manufacturing firms it is necessary that the amount of apparatus purchased from them should be considerable. Then when our Colonial and foreign friends come to this country for instruction and advice, and find that instruments of British manufacture are employed by the doyens of the scientific world, our foreign trade will develop, and increased production will then lead to lower prices with better quality.

B. H. Morphy, Man. Director,
The Cox-Cavendish Electrical Co., Ltd.
Twyford Abbey Works,
Acton Lane, Harlesden, N.W.10.
May 12.

Referring to Prof. Bayliss's letter on scientific apparatus from abroad, we cannot quite agree with his view that the instruments made in this country are more costly than those purchased from the Continent. We think that when conditions in this country are more settled Prof. Bayliss will find that foreign prices are equal to, if not in excess of, those ruling on this side, owing to the considerable increase in wages and raw materials. At the moment the rate of exchange makes the prices seem low as compared with those in this country, but can Prof. Bayliss obtain delivery at the low prices?

If manufacturers in this country do not receive the

support of the public, they cannot be expected to produce scientific instruments to compete with the standard of excellence obtained on the Continent—for several reasons, amongst which the following are the most important where microscopes are concerned.

The number of skilled lens-workers capable of making high-power objectives is very small, and to train suitable labour for, say, making 1/12-in. oil immersion objectives of the ordinary achromatic series could not be accomplished in less than three or four years. A dozen or so of these skilled workers could be given employment immediately.

The profit on microscopes is not very remunerative, and unless some protection such as importation under licence is established, no fresh capital is likely to be forthcoming; and even if it is, some years will elapse before those investing their money will see any return, on account of the time required to train labour for this highly skilled occupation.

If some protection is granted to the trade, the manufacturers must set a higher standard of excellence on their goods than they did before the war, otherwise they cannot expect support from the public; but if support is forthcoming we feel sure manufacturers will reciprocate by turning out goods not only at a lower price, but also of a better quality.

It was chiefly on account of the excellent standard attained that Continental manufacturers obtained the lead before the war. Individual pieces of apparatus have been made in England equal to any produced on the Continent, but, unfortunately, only a very small percentage of the supplies ever reached the standard. If English manufacturers will only pay more attention to inspection, and set a much higher standard of quality than they did before the war, there is no reason why the purchasing public should buy foreign-made instruments. There is also no reason why any instrument previously manufactured on the Continent should not be produced here.

C. BAKER.

244 High Holborn, London, W.C.1.
May 14.

WE do not think Prof. Bayliss and Mr. Munby will find that the prices of British-made laboratory apparatus have increased to the same extent as have those of some other manufactured articles—for example, leather or metal goods, soap, stationery, etc.

Last week a catalogue reached us from a well-known German firm specialising in certain optical goods. The pre-war prices are subject to an advance of 200 per cent., the basis of payment being 20 marks = 1*l.*, and cash to the value of 50 per cent. of the order is required at the time of placing it. Thus such imported goods are three times as costly as before the war.

At present the prices of our instruments are from 75 to 120 per cent. above pre-war German prices for instruments which are now admittedly more convenient and efficient. This is particularly the case in regard to one instrument, which for forty years prior to the war had been built by a German firm practically upside down.

Again, we supply certain optical testing instruments which are set at the National Physical Laboratory to an accuracy six times greater than was found in the standard instrument of German origin.

It would seem essential that the manufacture of scientific apparatus in this country should be encouraged to the fullest possible extent in order that trained workers may be available in emergency; for even supposing war to be impossible in the future, if such manufactures become the monopoly of another country we shall, sooner or later, be paying still higher prices by reason of that monopoly.

As no specific kind of apparatus is mentioned by Prof. Bayliss or Mr. Munby, we have replied as makers of two particular classes of optical testing instruments. These instruments are entirely British as regards optical and mechanical design, as no progress is to be made by adopting and copying designs which have easily demonstrable shortcomings.

BELLINGHAM AND STANLEY, LTD.

71 Hornsey Rise, London, N.19, May 10.

WITH regard to the letters by Prof. Bayliss and Mr. Munby in NATURE of May 6, we would say that, generally, we are in agreement with the report of the Branch Committee on Scientific Apparatus, of which I was chairman, an abstract of which is published in the report of the Engineering Trades (New Industries) Committee of the Ministry of Reconstruction.

We have very little sympathy with those who would bolster up our industry by levying heavy duties on imports, and, generally, we think that the result of such a policy would be to increase the cost of home-made goods without improving their quality; but there is a good deal to be said for preventing goods made abroad being dumped in this country at prices lower than those prevailing in the country of their origin. The inevitable result of permitting this is to discourage or kill our own industry, and this is well exemplified in the case of our watch industry.

Scientific men cannot, however, have dumped and, consequently, cheap scientific apparatus from abroad and at the same time a flourishing apparatus industry at home producing goods of the highest quality at the lowest prices.

WM. TAYLOR.
(Taylor, Taylor, and Hobson, Ltd.)

Leicester, May 11.

WITH reference to Prof. Bayliss's letter in NATURE of May 6, members of this association are in complete agreement that scientific workers should be able to obtain the very best quality apparatus.

I quote the wording of our communication to the Board of Trade (Scientific Instrument Branch) in connection with the proposal to form a special Licensing Committee on which scientific authorities would be represented: "They would have power to allow the imports of all apparatus which cannot be produced of efficient quality or in sufficient quantities in this country to meet the demands."

But the menace to British manufacturers is the abnormal rate of exchange with Germany, which enables apparatus to be brought in at anything from one-fifth to one-tenth of the normal value.

No workshop organisation or economy can possibly compete with such values, and it is during this unprecedented and abnormal state of international finance that British manufacturers are asking for temporary prohibition of imported apparatus at purely artificial prices.

Naturally Fractured Eocene Flints.

At a meeting of the Geological Society of London, held on May 5, Mr. S. Hazzledine Warren read a paper entitled "A Natural 'Eolith' Factory beneath the Thanet Sand." The discovery of flints fractured by natural pressure at the base of the Eocene is not, however, a novel experience, as, in 1910, M. l'Abbé H. Breuil described ("Sur la présence d'Eolithes à la base de l'Eocène Parisien," *L'Anthropologie*, t. xxi., 1910, pp. 385–408) in great detail, and by means of no fewer than seventy-six excellent illustrations, a series of flaked specimens of the same kind as those now put forward by Mr. Warren. Also, in 1914, I published an account of the flaked flints occurring in the Lower Eocene "Bull-head" bed at Bramford, near Ipswich (Proc. P.S.E.A., vol. i., part 4, pp. 397–404), and gave a full account of this peculiar deposit and the nature of the fractures exhibited by some of the contained flints. It will thus be seen that this question has been fully discussed and threshed out for many years past.

Through Mr. Warren's courtesy I was enabled, before the meeting at the Geological Society's rooms, to examine his material, and I at once recognised that the flake-scars to be seen upon the specimens showed every characteristic of those produced by pressure. Though of interest as corroborating earlier finds, Mr. Warren's flints have no bearing upon the specimens discovered by me in the Sub-Red Crag detritus-bed and other ancient deposits. The flaked flints which I have collected and claimed as humanly fashioned exhibit flake-scars produced by intelligently directed blows, as is clear to anyone examining them and familiar with the obvious and fundamental differences between pressure and percussion flaking. Further, it is also clear that these pressure-fractured Eocene flints are not comparable with the specimens first found by Mr. Benjamin Harrison, which have been known by that much misused term "eoliths."

International Council for Fishery Investigations.

The writer (X. Y. Z.) on this subject in Nature of April 29 seems to beat the air. There is no confusion of the general discussion with the deliberate statement of the council that "the study of the effect of the war in having closed great areas would materially assist the council in arriving at the most practical results." The closure of certain areas, for ten years or more, by the Scottish Fishery Board has already shown that such is without material effect on Nature's ways. Further, it is just the consideration of the almost valueless mass of certain statistics that, amongst other things, has led to the view that, judged by its promises and performances, the "International Council for the Investigation of the Sea," so far as the welfare of the British fisheries is concerned, is a serious waste of public money. The Development Commission's "almost judicial committee" cannot alter that conclusion. W. C. McIntosh.

Sea and Sky at Sunset.

In a note on the Royal Academy in Nature of May 6 "J. S. D." expresses disbelief in the possibility that a red sunset can give rise to a pure blue colour in the sea.

Last summer and autumn I occupied a small house on the French coast near Boulogne, and I had the good fortune to witness some of the most wonderful sunsets I have ever seen. The sun used to set across the Channel immediately in front of our windows, and the light of the setting sun was reflected not only in the sea itself, but also in the pools left by the tide along the seashore.

On several occasions when the setting sun was a deep crimson in a purple sky the sea was an intense blue, while the reflection on the water suggested molten gold. The contrast between the purple and crimson of the sky and the blue and gold of the sea was very beautiful, and the effect is not one which I shall readily forget.

As the sea is never free from ripples, it is possible that some of the light reaching the eye is transmitted through the water, but whatever may be the explanation there is no doubt about the reality of the effect.

K. E. Edgeworth.

Crowborough, May 9.

Readers of Nature will welcome Col. Edgeworth's description of what a sunset over the sea can be like, but those who have had an opportunity of studying the picture in this year's Academy to which reference was made will not find any difficulty in distinguishing between the reality as described by him and the artist's conception of the reality as seen at Burlington House.

As to Col. Edgeworth's description of sunsets seen over the English Channel, few who have spent holidays on a western sea-coast, or even on the reaches of a winding river like the Thames, can be unfamiliar with the pillar of gold seen in the water through the reflection of the sun's disc on the rippled surface. The golden reflection beneath the sun and the dark blue reflection beneath the sky may give rise to marked contrasts, but there is nothing unnatural in these. In the picture referred to it is far otherwise. The sun is not visible, but the whole sky is red, and where reflected light would cause innumerable spots of red upon the crests of the ripples no colour but blue is shown.

J. S. D.

Scientific Research.

In common with other subscribers to the Scientific Research Association, I recently received an intimation from the acting secretary and the treasurer that the support accorded to it was not sufficient to justify the establishment of the proposed organisation. There can, however, be no question of the importance of the aim the association had set itself—the promotion of research, irrespective of the economic advantages it may bring with it; and it may be some satisfaction to those who feel this to know that the National Union of Scientific Workers has formed a research council to promote the interests of research for its own sake. It is desired to make this council as representative as possible of every branch of scientific investigation. Communications from all who have the success of such a movement at heart should be addressed to the secretary of the National Union, Major Church, 19 Tothill Street, S.W.1, or to myself.

John W. Evans.

South Kensington, May 10.

Imperial Air Routes.

RECENT long-distance flights have shown that aerial navigation is a practical means of quick transport between distant lands. The long time occupied on the first flight to Australia is no criterion of the possibilities of the future, when the route is better surveyed and adequate aerodromes replete with all facilities are established. Sir Ross Smith recently spoke of six stages, each occupying a day, as a reasonable journey from London to Sydney. Air routes promise to forge a new link in Imperial unity, and to modify to a great extent the geographical relationships of the various parts of the Empire. Until now the ocean has been the link between the home country, the Indian Empire, the self-governing Dominions, and other oversea possessions. In that respect the British Isles are centrally situated as regards routes throughout the Empire; but for flying, the position of the home country is less favourable. An uncertain climate characterised by rapid changes of weather and much fog militates against successful aviation. Moreover, land connections in provision of aerodromes are an essential in air routes.

In a recent lecture before the Royal Geographical Society[1] Maj.-Gen. Sir Frederic H. Sykes described some of the most important of the probable Imperial air routes, and showed how they naturally centre on Egypt. The flight from Egypt to India was accomplished in November, 1918, and this route is one of the first which Sir Frederic Sykes advocates developing. From Kantara to Karachi a flight should occupy 36 hours, compared with the 9 days' steamer journey from Port Said to Bombay. Baghdad would gain more, being a 12 hours' flight from Kantara, and by the present mail route 3 weeks by sea from Port Said.

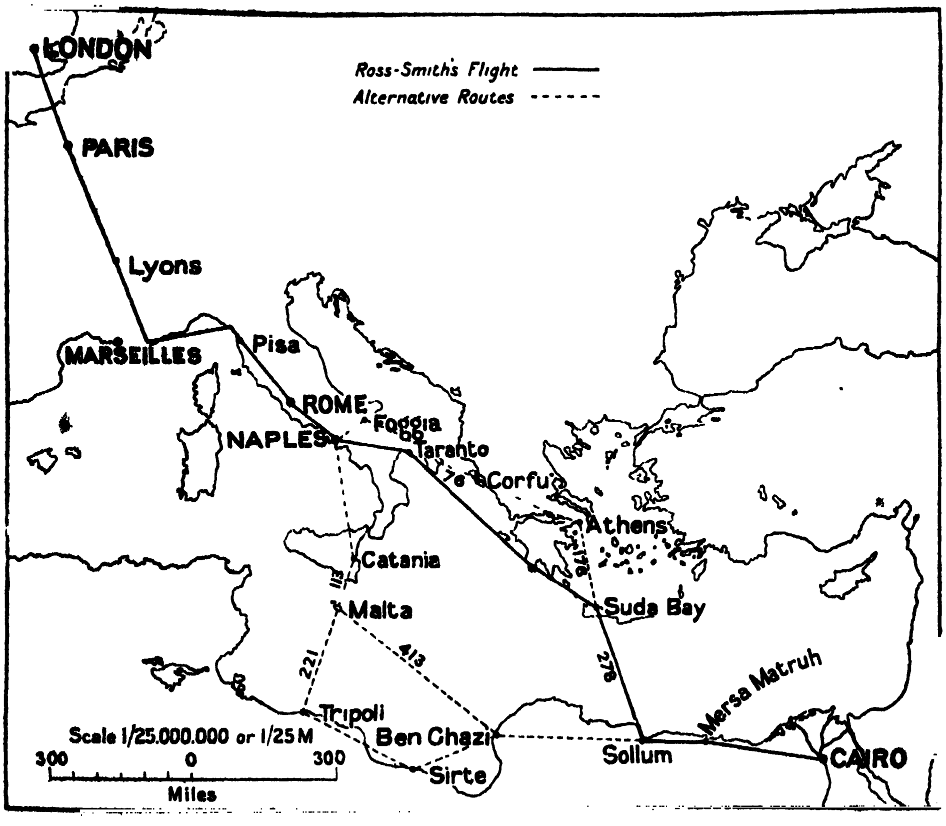

FIG. 1.—Air routes London to Cairo From the *Geographical Journal.*

In this connection it is important to realise that air traffic must pay its way if air routes are to become an established feature. Owing to the limitations in the weight that an aeroplane can carry, mails are the most suitable load. In their case also saving of time is a valuable consideration, and a return freight is ensured. Sir Geoffrey Salmond points out that the maintenance of a twin-engined machine, providing for a commercial rate of interest, works out on any route at about 10s. a ton per mile. An aeroplane carrying a ton, which is a fair cargo, must therefore earn 500*l.* on a 1000-mile flight, or about 1250*l.* on a flight from Egypt to Karachi. Little but mails could bear this cost, and, their carriage being a Govern-

[1] *Geographical Journal*, vol lv., No. 4, April, 1920.

ment monopoly, could in cases of advantage be partly transferred to air routes. Speed may in time be increased in two ways—first, by the improvement of ground organisation, so as to permit night flying with a relay system; and secondly, by improvement of the engine.

Sir Frederic Sykes quotes some remarkable figures to show the comparatively small risk in flying. During the last eight months of 1919 the total mileage flown by the principal firms engaged in civil aviation was 593,000, and the passengers carried totalled 64,416. During this period only four pilots and one passenger were killed, and six pilots and ten passengers injured. This small proportion of casualties will no doubt be reduced as machines are perfected, ground organisation improved, and air surveys carried out. The close association of the Meteorological Office with the Department of Civil Aviation is a happy augury for the future, and the International Air Convention, to which most of the Allies, and several neutrals, have subscribed, should help to co-ordinate efforts in civil aviation.

The consideration of good landing-places to a large extent controls the course of air routes. From Egypt the route to India is direct from Kantara to Damascus and Baghdad, thence to Basra, Bushire, and along the shores of the Persian Gulf and Arabian Sea to Karachi. Through India two routes to Calcutta are suggested—a northern one *via* Delhi, Cawnpore, and Allahabad, which is part of the route to Australia; and a southern one by Ahmadabad, Bombay, and Nagpur. On both routes aerodromes are already built or under construction, and there is now an aerial postal service between Karachi and Bombay. The Australian route from Calcutta goes *via* Akyab to Rangoon, whence a stretch of hazardous flying over mountainous country leads to Bangkok. The route continues *via* Singapore, Java, and Dutch Timor to Port Darwin. The latter stages of the journey offer difficulties in suitable landing-places. Alternative routes are proposed, and have been partly surveyed, and it is even suggested that the use of Dutch territory might be avoided by a route from Singapore to Australia *via* Christmas Island. This would entail two stages of 810 and 950 miles respectively, to say nothing of the possible difficulties of aerodrome construction on Christmas Island.

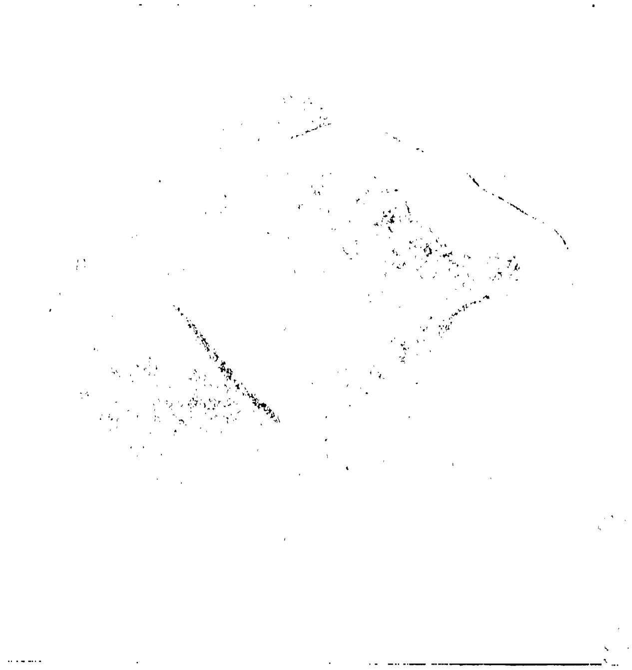

FIG. 2.—Canea from the east. From the *Geographical Journal.*

Routes from Egypt to Cape Town, and from England to St. John's (Newfoundland), Toronto, Winnipeg, and Vancouver are also suggested by Sir Frederick Sykes. The route from England to Egypt, although flown numerous times, presents difficulties, especially in Italy and the eastern Mediterranean. An alternative, but longer, route is tentatively suggested from Naples *via* Sicily, Malta, Tripoli, and the northern coast of Africa. The chief problem seems to be in the provision of a suitable aerodrome at Malta, for, once the African coast is reached, favourable conditions are found.

Helium: Its Discovery and Applications.

By DR. WILLIAM J. S. LOCKYER.

THE year 1868 is rendered memorable in the advancement of solar physics by the fact that the spectroscope was first used on an eclipsed sun. Up to that time the composition of the prominences and corona was unknown, although both these phenomena were then proved to be truly solar, the result of diligent systematic application of photography to eclipse problems since the year 1860.

On August 18, 1868, a total solar eclipse occurred in the Indian and Malayan peninsulas, lasting for about five minutes and thirty-eight

seconds. This event afforded astronomers an opportunity of applying the spectroscope, in conjunction with the telescope, to determine what the prominences were really made of. On this occasion not only were all the expeditions successful, but an almost identical discovery was also made by the numerous observers.

It was observed that the prominences gave spectra of bright lines, and, with the means of recognition available at the few moments of totality, the red, green, and blue lines which were seen were attributed to the gas hydrogen, while the strong, bright yellow line was stated to be due to the luminous emission of sodium.

During this eclipse the distinguished French astronomer, Janssen, was so struck with the brilliancy of the prominence lines in his spectroscope that he considered it certain he would be able to see the bright lines without an eclipse at all. This

It is interesting as a matter of history to refer here to the first communication which Lockyer made to the Royal Society with reference to his first successful observation.

October 20, 1868.

SIR,—I beg to anticipate a more detailed communication by informing you that, after a number of failures, which made the attempt seem hopeless, I have this morning perfectly succeeded in obtaining and observing part of the spectrum of a solar prominence.

As a result I have established the existence of three bright lines in the following positions:—

(i) Absolutely coincident with C.
(ii) Nearly coincident with F.
(iii) Near D.

The third line (the one near D) is more refrangible than the more refrangible of the two darkest lines by eight or nine degrees of Kirchhoff's scale. I cannot speak with exactness, as this part of the spectrum requires re-mapping. . . .

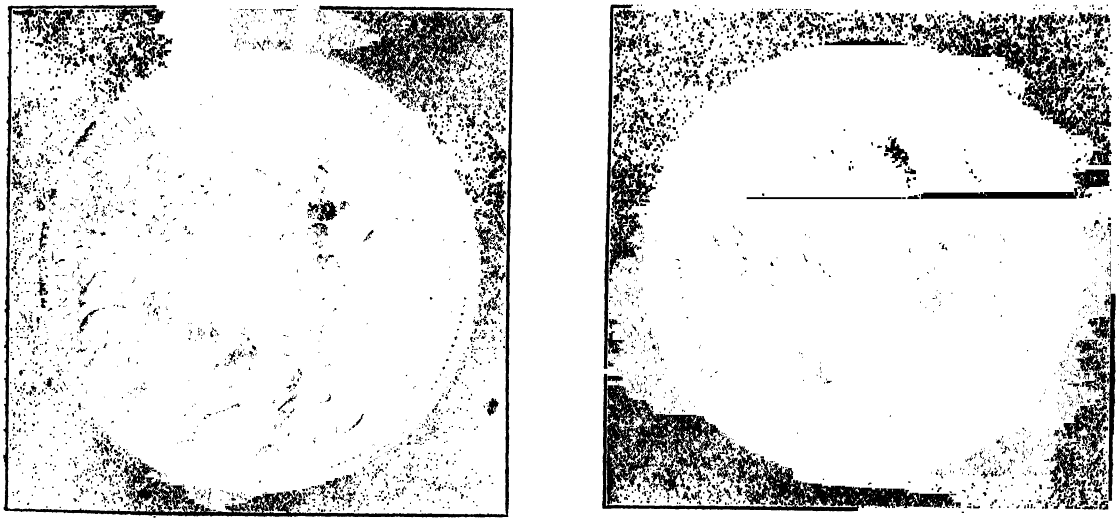

FIG. 1.—Medal struck by the French Government in honour of the joint discovery of the composition of the prominences by Janssen and Lockyer in the year 1868.

he did during the following seventeen days which he spent at the eclipse station, observing the prominences on the limb of the sun.

The achievement of Janssen was based upon principles which in 1866 had been placed before the scientific world by Sir Norman Lockyer. Owing, however, to regrettable delays in the delivery of the instrument which was ordered in the beginning of the year 1867, and being specially made for him from funds supplied from the Government Grant Committee, Lockyer did not receive it until October 16, 1868. He first used it on October 20, observing the bright lines which had been recorded in the August eclipse.

Both Janssen and Lockyer communicated the results of their discoveries to the Paris Academy of Sciences, and these despatches arrived a few minutes of each other on the same day. In honour of the joint discovery the French Government struck a special medal (Fig. 1).

From the above it will be noticed that Lockyer gives the position of the bright yellow line as near D, and not coincident with D, D being the lines of emission of sodium previously referred to.

With regard to the behaviour of this line, he states in a later communication (November 19, 1868):—

There is a line in the yellow, most probably proceeding from the substance which gives off the light at C and F, as the length of this line, as far as the later observations with the more correctly adjusted instrument go, is the same as that of those in C and F.

This statement shows that the yellow line behaved like the lines of hydrogen, and the view put forward then was that probably this line might be due to hydrogen also. The line was called D_3 to differentiate it from the double line of sodium D_1 and D_2.

A considerable amount of work was now done

with regard to D_3, for no substance was found in the laboratory which could produce this line.

By studying the behaviour of D_3 in relation to the hydrogen lines, throwing the image of the sun's limb on to the slit of a spectroscope, Lockyer found that the lines were distorted—*i.e.* there were changes of wave-length due to movements of the material in the sun. The orange line was, however, observed to behave quite differently from either of the hydrogen lines, showing that a different substance was in question.

Hence [as Lockyer remarks] we had to do with an element which we could not get in our laboratories, and therefore I took upon myself the responsibility of coining the word *helium*, in the first instance for laboratory use. At the time I gave the name I did not know whether the substance which gave us the D_3 was a metal like calcium or a gas like hydrogen, but I did know that it behaved like hydrogen, and that hydrogen, as Dumas had stated, behaved as a metal ("Sun's Place in Nature," p. 33).

In the following years numerous other lines in the sun and stars were found associated with the yellow line, but the origins of these were all *unknown* and designated as such.

It was not until the year 1895 that the terrestrial equivalent of this well-known yellow and other lines was discovered. "In the course of investigations on argon," so wrote Sir William Ramsay in a communication to the Royal Society (Proc. Roy. Soc., vol. lviii., p. 65) on March 26, 1895, "some clue was sought for which would lead to the selection of one out of almost innumerable compounds with which chemists are acquainted with which to attempt to induce argon to combine."

Acting on a suggestion by Sir Henry Miers, who directed attention to the work of Dr. Hillebrand in 1888 on the occurrence of nitrogen in uraninite, etc., Sir William Ramsay employed the mineral clèveite, essentially a uranate of lead containing rare earths. He treated this mineral, and from it extracted a small quantity of gas, which he subjected to spectroscopic examination. To use his own words, as printed in the above-mentioned communication :—

Several vacuum tubes were filled with this gas and the spectrum was examined, the spectrum of argon being thrown simultaneously into the spectroscope. It was at once evident that a new gas was present along with argon.

Fortunately, the argon tube was one which had been made to try whether magnesium poles would free the argon from all traces of nitrogen. This it did; but hydrogen was evolved from the magnesium, so that its spectrum was distinctly visible. Moreover, magnesium usually contains sodium, and the D line was also visible, though faintly, in the argon tube. The gas from clèveite also showed hydrogen lines dimly, probably through not having been filled with completely dried gas.

On comparing the two spectra, I noticed at once that while the hydrogen and argon lines in both tubes accurately coincided, a brilliant line in the yellow, in the clèveite gas, was nearly, *but not quite*, coincident with the sodium line D of the argon tube. Mr. Crookes was so kind as to measure the wave-length of this remarkably brilliant yellow line. It is 587·49 millionths of a millimetre, and is exactly coincident with the line D_3 in the solar chromosphere, attributed to the solar element which has been named *helium*.

Thus was the terrestrial equivalent of the helium line discovered after an interval of twenty-seven years.

Solar observations had shown that this line was observed high in the chromosphere, indicating that the density of the gas should be very low. Special interest, therefore, attached to the determination of this important property. In a preliminary experiment Sir William Ramsay obtained 3·9 as a maximum number for the density of helium, oxygen being 16, thus showing that the surmise was correct. Soon after this discovery Lockyer prepared some of the gas from bröggerite, and established the fact that numerous lines, designated "unknown," in the spectra of the chromosphere, nebulæ, and stars, were due to this gas.

Thus from an observation of the sun a new terrestrial gas was discovered, and from this terrestrial gas the origins of a host of unknown lines in the spectra of the heavenly bodies were explained.

Like hydrogen, helium has a wide diffusion in space, for not only is it in strong evidence in the hot stars, but it also must occur in such cooler stars as Arcturus, since this star is at about the same temperature as our sun, in which we know helium is present. In our atmosphere helium is one of the rarer constituents, being present in the proportion of about one volume in 250,000.

Up to the last few years the amount of helium which has been collected has been small, owing to the costly process of obtaining it, but during the war a demand for it in large quantities arose because of its lightness and non-inflammable nature. Helium is the lightest gas known next to hydrogen, of which it has about 92 per cent. of the buoyancy or lifting power. It was intended to supply a fleet of airships with this gas, and great fractionating plants were laid down in the United States of America capable of separating helium from natural gas at a very moderate cost. It was due to the above-mentioned demand that helium became more widely known, and attention was at once paid to bring together all the information that had been published about it as an aid to that enterprise.

The U.S. Department of Commerce took the matter in hand, and under Dr. S. W. Stratton, the director of the Bureau of Standards, a bibliography of scientific literature relating to helium was compiled. The information (more than 400 references) thus brought together has since (September 10, 1919) been published in pamphlet form in a Circular of the Bureau of Standards (No. 81), and will be found a very valuable source of reference.

The importance of helium to-day may be briefly summarised from the following extract from the introduction to this circular :—

Helium has probably been the most interesting of

all the elements to the theoretical scientist on account of the romantic history of its discovery, its occurrence in a remarkable condition of solid solution in many minerals, its formation as a product of the disintegration of the radio-active elements, its liquefaction after a decade of unsuccessful attempts by some of the world's greatest experimenters, the attainment by its use of temperatures below those at which the resistances of pure metals vanish, its many unique physical properties, and the many important theoretical conclusions which have been drawn from its behaviour.

All of these points of interest have been the subjects of very thorough investigation. The important developments of the future will probably be along the line of the applications of helium, many of which have already been suggested.

New Conceptions of Psychology.

THE results of Dr. Henry Head's clinical investigations[1] are exceptionally interesting from the philosophical point of view, for they are utterly incompatible with the older ideas of the introspective psychologists. In fact, his work is "a complete scientific refutation of all psychological theories which build up knowledge out of original sense-material" (NATURE, November 6, 1919, p. 267). Dr. Head has demolished the old psychology and created a new conception, in accordance with which "sensations depend neither for their existence nor for their psychical quality on the cerebral cortex, which has a purely interpretative function in regard to them."

The function of the cerebral cortex in sensation is to endow it with spatial relationships, with the power of responding in a graduated manner to stimuli of different intensities, and with those qualities by which we recognise the similarity or difference of objects brought into contact with the body. The old psychologists held that there was something in the external universe corresponding to primary sensations, which they regarded as being combined into the elements of perception. In accordance with such views the changes at the periphery were simple and became more complex the nearer they approached the highest centres in the brain. By submitting himself to a surgical operation in 1905 Dr. Head was able to demonstrate the complexity of the peripheral changes and the diffuseness of the impressions received. Moreover, by his clinical studies—monuments of patient research and marvellous insight—he has shown how these multitudes of diffuse peripheral changes gradually become integrated and rendered more specific in quality, space, and time as they approach the highest physiological levels in the central nervous system. The recognition of these facts gives an indication of the mode by which evolution has brought into existence such a nervous system as that of man. Lower, more impulsive, and less specific reactions become dominated by those that admit of choice. This conception turns orthodox psychology upside down.

Man's conceptions of space, time, and material rest ultimately on the nature of the spatial and temporal elements in sensation. These in turn are founded on complex physiological activities, many of which may never disturb consciousness directly; although they do not enter into the province of introspective psychology, they are responsible for much that is usually attributed to the action of the mind. Dr. Head's work on the cerebral cortex represents the culmination of an intensive investigation of the sensory system upon which he has been engaged for more than a quarter of a century. In 1893 he was studying the phenomena of the localisation of the pain associated with visceral disturbances and incidentally mapping out the distribution of the sensory nerves. Then he began the analysis of the components of the sensory nerves; and to test the problems that called for solution he invited Mr. James Sherren to cut one of the main sensory nerves of his (Head's) arm, and with the help of Dr. Rivers he studied the process of the restoration of function in the severed nerve. By this means he was able to differentiate between the three kinds of sensory nerves distributed to his arm:—

(a) The deep afferent system supplying the connective-tissues, muscles, joints, and tendons, in virtue of which is conferred the power of recognising movement and appreciating the position of any part of the limb, as well as of localising pressure and responding to certain aspects of pain;

(b) A punctate afferent mechanism in the skin, which Dr. Head has called "protopathic," the primitive nature of which is shown by the early restoration to activity (a little more than six weeks in Dr. Head's arm) of its end-organs after the nerve has been reunited, by the specific nature of the response of each set of end-organs, and by the diffuse "all-or-nothing" nature of the response, *i.e.* the absence of any graduation corresponding to the intensity of the stimulus; and

(c) Superimposed over this older mechanism another cutaneous system of later development and higher functions, which Dr. Head calls "epicritic." Epicritic sensibility is not restored for many months after the reappearance of protopathic sensibility, the diffuse reaction of which is then checked and controlled; and the effects of stimulation are modulated according to the intensity and locality of the exciting agent. It is concerned with the finer degrees of tactile and thermal discrimination and is opposed to, and controls, the diffuse "all-or-nothing" reaction of protopathic sensibility.

It has long been known that the sensory paths in the central nervous system had a twofold terminus, represented by the thalamus and the cerebral cortex. It remained for Dr. Head to interpret the meaning of this arrangement. He

[1] "Sensation and the Cerebral Cortex," *Brain*, vol. xli., part ii., 1918.

showed that the thalamus is concerned with the affective side of consciousness, and deals with crude awareness to contact, heat, cold, and pain; while the sensory cortex exercises the *rôle* of discrimination and endows the basic functions of the thalamus with spatial qualities, intensity and relativity.

The war afforded Dr. Head the opportunity for testing his theories as to the functions of the sensory cortex on a large scale. He made an intensive study of fifty men with strictly localised bullet wounds of the post-central convolution and the areas adjoining it in front and behind: as the result he has revolutionised our conceptions of the nature of the work of the cerebral cortex.

Destruction of the sensory cortex causes a dissociation between the spatial and the qualitative aspects of sensation. The patient loses the power of recognising movements or the posture of the affected parts: he can no longer localise the position of the stimulus, or respond adequately to variations in its intensity: he has no idea of the size, shape, weight, or texture of an object in contact with his body. Yet he can appreciate the tactile, painful, and thermal aspects of the impressions it evokes.

Thus it is possible to recognise the qualitative aspects of a sensation without of necessity obtaining any information concerning the stimulating object, as a constituent of the external world. Sensory qualities, and the affective states with which they are associated, are in themselves discontinuous. They are relative to ourselves, and appear and disappear in consciousness, without leaving any connective factor in the activities of the mind.

On the other hand, the projected aspects of sensation relate these qualities, not to ourselves, but to the external world. An "object" might be defined as a complex of projected sensory responses. These functions of the cortex are not only responsible for sensory projection in space, but also ensure recognition of sequence in time.

The power of recognising serial movements in both space and time seems to be based on the same physiological processes. They give us a direct appreciation of succession: this is translated into sensations of serial movement in either space or time, according to the nature of the concomitant sensory impulses.

These physiological responses, which are so clearly bound up with the activities of the sensory cortex, are characterised by a strict dependence on past events. All projected sensations leave behind them a coherent train of physiological dispositions: thus a movement occurring at one moment is measured against the consequences of those which have preceded it.

It is difficult to estimate the magnitude of the vast revolution in our conception of the functions of the cerebral cortex that we are witnessing. Moreover, Dr. Head's work lays the foundation of a new and true psychology and illuminates the age-long problem of the relationship of body and mind. It is a matter for just pride that we owe this new vision to an Englishman.

Obituary.

Principal R. M. Burrows.

King's College and the whole University of London have suffered grievous loss by the death of Dr. Ronald Burrows. Born on August 16, 1867, Dr. Burrows went from Charterhouse to Christ Church, Oxford, with a scholarship, and took his degree in 1890 with first class honours in Classical Moderations and *Literae Humaniores*. After five years as assistant to Prof. Gilbert Murray, who then held the Greek chair at Glasgow, he was appointed professor of Greek at Cardiff in 1898, and rejoined his Cardiff colleague, Dr. R. S. Conway, as Greek professor in Manchester in 1908. By travel, during these years, in the Mediterranean, he had gained valuable experience of topography and excavation, and also that first-hand knowledge of the modern politics of Greece and the Balkan States which served him so well in later years. His published work, mainly about Greek battlefields, ancient sites in Bœotia (where he conducted most instructive excavations at Rhitsona and the Delion), and the newly revealed Minoan civilisation, gained him the degree of D.Litt. in the University of Oxford in 1910, and his "Discoveries in Crete," published in 1907, went into a third edition.

An excellent scholar, a vigorous and fluent writer, and a teacher of untiring drive and wide humanity, Dr. Burrows contributed much to "save Greek" during a difficult period by the simple and characteristic method of making his pupils interested in it, and infecting them with his own keenness; and this did not stop "out of school." His lifelong interest in young lads, and his strenuous and successful work for the Cardiff University Settlement and for the Ardwick Lads' Club at Manchester, were for him all of a piece with the "humanities" of which his Greek studies should be the crown. He enjoyed life and enjoyed people, and his sunny temper and good fellowship were the happy counterpart of his learning and judgment.

Dr. Burrows moved from Manchester to King's College as principal in 1913, at a time of crisis and manifold difficulty. Apart from other qualifications, he had, as was said, "more bishops in his family" than had all the other candidates put together, and more experience, too, than most of other "happy families" where sciences and arts could "live and let live." His width of interests and sympathies, enabling him to bring in new subjects to restore the balance between them and the old; his ready speech and debating skill; and his real grasp of principles and policies, gave him a position which experience con-

firmed. The college organisation for modern languages, literatures, and national histories, which best commemorates him, was conceived and founded just in time for the war, which so fully endorsed his foresight and amplified his opportunities, less perhaps among the Romance languages than in the Slavonic and modern Greek departments which lay nearest to his personal interests. Knowing as intimately as he did the problems and the possibilities of the city-state world of ancient Greece, he was able in an exceptional way to interpret here the ideals, no less than the failures, of the Balkan peoples, whom he understood and impressed like the naughtier boys in his settlement clubs. Honours conferred by the Greek and Serbian Governments, and the close personal relations which he maintained with leaders such as M. Venizelos and President Masaryk—the latter one of his professors until his own country claimed him—are testimony enough on this side, and he just lived to see in the act of realisation much for which he had long striven. Such a man would not spare himself, and he would lavish help and encouragement along the whole breadth of his interests at times when only the greatest prudence could have preserved his health; but so he loved to live.

WE regret to announce the death in London on May 6 of DR. J. HAMILTON FULLARTON, so long associated with scientific fishery research in Scotland. Dr. Fullarton was born at Brodick, Arran, in 1856. He had a distinguished career as a student at Glasgow University, taking many prizes and bursaries, and graduated M.A., with the highest honours in natural science, in 1881, and D.Sc. ten years later. After acting for some years as assistant to the professor of natural history in his *alma mater*, Dr. Fullarton entered the service of the Fishery Board for Scotland as a naturalist on the scientific staff in 1889, a post which he held for eight years. On quitting the Fishery Board service, Dr. Fullarton studied medicine with a view to a medical career, and received the qualifications of L.R.C.P. and L.R.C.S.(Edin.). After serving for a short period as medical officer on an Atlantic liner, he settled in London as a consultant, and gradually built up a considerable practice. Prior to this, on the initiation of the international fishery investigations, Dr. Fullarton re-entered the service of the Fishery Board, and did valuable work for a year in the supervision of the scientific investigations on board the research steamer *Goldseeker*. It is as an expert on fisheries that he will be chiefly remembered in scientific circles. He devoted himself in particular to the study of shellfish, such as the common edible mussel, the oyster, the cockle, and the "clam," and wrote numerous papers on their cultivation and natural history. In connection with this branch of his fishery work Dr. Fullarton on more than one occasion visited the districts in France and Holland where oyster-culture and mussel-culture are principally carried on. He also made a useful series of researches on the breeding and development of the European lobster.

THE death is announced at Copenhagen of the well-known Danish philologist, PROF. L. F. A. WIMMER, at eighty-one years of age. Prof. Wimmer was the author of an important book on the Runic alphabet, "Runeskriftens oprindelse og udvikling i Norden," published in 1874, in which he suggested that the Runes were really Latin letters adapted for carving in wood, and of four volumes on Runic inscriptions in Denmark. In several of the Sagas it is recorded that Runes were inscribed on round pieces of wood, called *Kefli*, or Runic sticks. It has been suggested that the Eddas were recorded in this way, but the evidence is not quite satisfactory.

THE bearer of a name highly esteemed in botanical circles has just passed away in the person of AUGUSTIN PYRAMUS DE CANDOLLE, who died at Vallon, near Geneva, on May 9, at the age of fifty-one, surviving his father only eighteen months. The family is of French origin, but for four generations it has been settled at Geneva, adopting the local fashion of employing a capital letter for *De* Born in England in 1869, the late botanist visited our shores on many occasions; in 1889 he came to London to receive the Linnean gold medal awarded to his grandfather by the Linnean Society of London, and in 1904 he attended the British Association meeting at Cambridge. He published but little, only about a dozen short memoirs on systematic descriptions of new plants from Madagascar and Tonquin, on parthenogenesis, and on the influence of electricity on the germination of seeds. He filled the office of president of the Société Botanique de Genève in 1905. The brilliancy of the line was shown in the great-grandfather, A. P. De Candolle (1778–1841); grandfather, Alphonse De Candolle (1806–93); and father, Casimir De Candolle (1836–1918).

BY the death, on February 27, of ALFRED J. MOSES, professor of mineralogy at Columbia University, the science of mineralogy has lost (says "H. P. W." in *Science*) one of its most eminent and valued exponents. Prof. Moses's work as a teacher, as a writer, and as a scientific investigator can scarcely be too highly esteemed, and his loss to all branches of his profession is most keenly felt. His text-book on "Mineralogy, Crystallography, and Blowpipe Analysis" will for many years remain the standard in a large majority of the universities in which courses in these subjects are given. His work on "The Characters of Crystals," published in 1899, is the first treatise published in America upon physical crystallography, a branch of crystallography which was early recognised by him as of primary importance to chemists, geologists, and mineralogists, and has within very recent years assumed a scope and developed practical applications which have more than justified his early visions of its future.

Notes.

THE general meeting of the Linnean Society on June 17 will be devoted to a celebration of the centenary of Sir Joseph Banks (1743–1820) with essays on various aspects of his life-work, and an exhibition.

DR. H. D. CURTIS, astronomer at the Lick Observatory, has been appointed director of the Allegheny Observatory in succession to Dr. Frank Schlesinger, who assumed charge of the Yale Observatory on April 1.

THE Linnean Society has elected the following as foreign members:—Prof. Gaston Bonnier, Prof. Victor Ferdinand Brotherus, Prof. Giovanni Battista de Toni, Prof. Louis Dollo, Prof. Paul Marchal, and Prof. Roland Thaxter.

THE Natural History Museum Staff Association has arranged a special scientific reunion to be held at the museum (by permission of the Trustees) on Thursday, June 3, at 3.30 p.m., in connection with the Imperial Entomological Conference. The exhibits which will be shown will illustrate some of the problems of economic interest, or arising out of the war, which have been studied at the museum during the past few years.

THE motion for the second reading of the Importation of Plumage (Prohibition) Bill was carried in the House of Commons on May 14. Lt.-Col. Archer-Shee expressed a wish to propose that it be an instruction to the Standing Committee by which the Bill will be considered to insert a schedule of the birds the plumage of which should be prohibited from importation, but the Speaker pointed out that it would be out of order to give a mandatory instruction to a Standing Committee, which could, if it wished, take such action without any instruction.

A NOTICE from the Department of Anatomy, Johns Hopkins Medical School, Baltimore, Maryland, informs us that the Ellen Richards research prize offered by an association of American college women, hitherto known as the Naples Table Association, is available for the year 1921. This is the tenth prize offered. The prize has been awarded four times, twice to American women and twice to Englishwomen. The competition is open to any woman in the world who presents a thesis written in English. The thesis must represent new observations and new conclusions based upon laboratory research.

THE medal of the Society of Chemical Industry for 1920 has been awarded to M. Paul Kestner in recognition of his distinguished services to chemical industry. The medal is awarded biennially, and among the recipients in recent years have been the Right Hon. Sir Henry Roscoe (1914), Mr. C. F. Cross (1916), and Sir James Dewar (1918). M. Kestner was born in Alsace prior to the German occupation in 1871; he was one of the chief founders and the first president of the Société de Chimie Industrielle in France, which was established in 1917. He has been connected with engineering as applied to chemical industry throughout his career, and among his more notable achievements are the use of forced draught in acid towers, automatic acid elevators, the climbing film evaporator, the scaleless water-tube boiler, and several inventions in connection with beet-sugar manufacture.

AN invitation from the Mayor and Corporation of Barrow-in-Furness to hold the annual autumn meeting of the Institute of Metals in that town on Wednesday and Thursday, September 15 and 16 next, has been accepted by the council of the institute. Particulars of the meeting can be obtained from the secretary, Mr. G. Shaw Scott, 36 Victoria Street, S.W.1, who will also be glad to forward tickets for the tenth annual May lecture, which will be delivered by Prof. C. A. F. Benedicks, of Stockholm, at 8 p.m., on June 10, at the Institution of Mechanical Engineers, Westminster, the subject of the lecture being "The Recent Progress in Thermo-Electricity." The president, Engineer Vice-Admiral Sir George Goodwin, K.C.B., will preside.

A SHORT account of the Department of Scientific Research and Experiment, which the Admiralty has set up under the Third Sea Lord, was given in NATURE of April 22, p. 245. A vote for 302,000*l.* for scientific services under the Navy Estimates was agreed to in Committee of the House of Commons on May 17. Mr. Long, in reply to points raised concerning this vote, said that after an investigation into the conditions the Government decided to ask the Lord President of the Council, who was specially charged with the care of all scientific work in the country, to set up a Committee to inquire into the whole of the work done in the Government Departments in order to prevent overlapping, and to prevent two Departments doing the same work. The Admiralty had appointed a Director of Scientific Research at Teddington, where they were going to concentrate on naval scientific research. When it came to sea-water research they proposed that that should be carried out at the sea-ports. Teddington would be carried on this year, but they hoped that before the end of that time they would have the benefit of the report of the Lord President's Committee, and they would then be in a position to avoid overlapping and duplication of work. The Admiralty would not hesitate to ask Parliament for such money as they thought necessary to give the fullest effect to scientific research and the development of the results of that research. The sum of 430,300*l.* was voted for educational services, and Mr. Long said in connection with it that the departure, taken only recently, under which reception was secured at the University of Cambridge for a certain number of naval officers as undergraduates, had abundantly justified itself. He assured the Committee that the Government is extremely sympathetic to this scheme, and hopes to increase the number of officer undergraduates.

AN interesting conference on "The Relations of the Inventor to the State," organised by the Institute of Inventors, was held at the rooms of the Royal Society of Arts on May 13. The discussion was opened by Mr. D. Leechman, who gave a good *résumé* of the present state of the patent law in the light of the new Patent Act. It was remarkable that in a meeting

of this kind the whole of the speakers were unanimous in condemning the present attitude in official circles towards inventors. It was stated by more than one speaker that those who came forward during the war with ideas and inventions that had made our success possible had not only received no reward, but had in several cases been deprived even of the merit of their ideas by officials who were themselves devoid of the necessary technical or scientific knowledge. The chairman, Mr. Walter F. Reid, stated that the working of the Royal Commission on Awards to Inventors supplied abundant evidence of the difficulty experienced by inventors in obtaining any recognition. Although large sums were now being devoted to research, he pointed out that such work was only the raw material for the development of industry; it was the application of that raw material by the inventor which resulted in the advance of industrial processes. The mass of facts as ascertained by research was already enormous; what is now required is inventive genius to make use of those facts, which Mr. Reid compared to the bricks and stones with which an architect might produce a building, but which by themselves were of little practical use.

INFLUENZA, according to the Registrar-General's return for the week ending May 1, continues greatly on the decline over the whole country, the deaths for the ninety-six great towns numbering only 202 and in London 45. For the twenty-eight weeks from October 25, 1919, to May 1, 1920, during which influenza was practically epidemic, the deaths from the disease in London were 1160, and the deaths from all causes 35,276. Deaths from influenza were 3 per cent. of the total deaths, whilst the deaths from pneumonia were 11 per cent. and from bronchitis 10 per cent. Between the ages 0 and 20 the deaths from influenza were 15 per cent. of the total, 20 to 45 years 36 per cent., 45 to 65 years 28 per cent., and above 65 years 21 per cent. The age-incidence of the deaths calculated on the total deaths for the several ages was respectively 4 per cent. for 5 to 20, 8 per cent. for 20 to 45, and 4 per cent. for 45 to 65. The insignificance of this is shown when compared with the deaths during the virulent epidemic of 1918–19, in which during thirty-one weeks from October 19, 1918, to May 10, 1919, the deaths from influenza were 47 per cent. for ages 5 to 20 of those for the corresponding ages from all causes, 52 per cent. for 20 to 45, and 22 per cent. for ages 45 to 65. During the three weeks ending April 10, the worst stage of the present epidemic, the deaths between 20 and 45, the ages attacked most severely, were only 21 per cent. of the total deaths from all causes, whilst in the epidemic of 1918–19 the deaths for ages 20 to 45 in the three weeks ending November 16, 1918, were 73 per cent. of the total at the corresponding ages from all causes. In the present epidemic deaths were most numerous during a spell of exceptionally mild weather.

A BRIEF, but very interesting, study of the pygmies of Central Africa by Mr. Herbert Lang appears in *Natural History*, the journal of the American Museum of Natural History (vol. xix.), and its value is further enhanced by a number of most excellent photographs. Anthropologists will welcome this contribution, since it summarises the results of a prolonged study of these people made during the American Museum Congo Expedition (1909–15). During that time more than a hundred life-masks, representing sixteen different tribes of Central African races, were taken. Some extremely useful observations on the physical characteristics of the pygmies are made, as well as on their mode of life, customs, and language. By way of a supplement, perhaps, to Mr. Lang's paper, this number also contains an essay on "The Pygmy Races of Man," by Mr. Louis R. Sullivan, of the Anthropological Department of the American Museum, illustrated by a number of useful tables and diagrams.

THE eighteenth annual report of the Rhodesia Museum, Bulawayo, affords instructive reading. It is evident that but for the assistance the museum is able to afford the mining industry it would cease to exist. The public generally seems to regard the institution, at most, with but a mild interest. Hence, from lack of funds, every aspect of its work is hampered. The building is all too small to house its collections, and the provision made for the storage and exhibition of specimens is utterly inadequate. It is more than probable that if a better display could be made enthusiasm might be kindled. This state of affairs is lamentable, for, as matters stand, it is impossible to secure that record of the fauna and flora of this important area of Africa which is so essential in a country being rapidly transformed by the march of civilisation. Dr. G. Arnold, the curator, is evidently having an uphill fight; but, in the interests of science, it is to be hoped that the tremendous possibilities of a well-organised museum will soon be realised.

THE Pueblo stage of culture in south-western Colorado, New Mexico, Arizona, and Utah, the domain of the cliff-dwellers, has naturally attracted much attention. The material for studying it is wide and scattered, and it is well that a competent archæologist, Mr. J. W. Fewkes, has prepared a monograph on the subject, entitled "Prehistoric Villages, Castles, and Towers of South-Western Colorado," published as Bulletin No. 70 of the Bureau of American Ethnology. The general conclusions at which Mr. Fewkes has arrived are: The buildings express the communal thought of the builders, since they were constructed by groups of people rather than by individuals. The view that either the Pueblo people were derived from Mexican tribes or, as it was customary in the seventeenth and eighteenth centuries to suppose, their descendants had made their way south and developed into the more advanced culture of the Aztecs, is not supported by architectural data observed among these two peoples; it is preferable to assume that the custom of building stone houses was not derived from any locality not now included in the Pueblo area, but that it developed as a local growth, the earliest stages, as well as the most complex forms, being of local origin. That the buildings antedate the coming of the white men is shown by the absence of mention of them in any history; no European objects have been found at the Pueblos, and the buildings and pottery have no affinity with any villages inhabited when the Spanish entered the south-west.

EXPERIMENTS with the Amphipod *Gammarus chevreuxi* by E. J. Allen and E. W. Sexton at the Plymouth Marine Biological Laboratory (*Journal of Genetics*, vol. ix., No. 4) have disclosed several mutations in eye-colour. In the wild animal the retinal pigment is black. A single individual with red eyes appeared in the second generation from animals brought into the laboratory, and the new character was inherited as a simple recessive. An albino-eyed type also appeared, in which the eyes differed in many structural features from the normal type. Another mutation, by no means uncommon, consists in the loss of the white pigment normally present between the ommatidea of the eye. This may appear suddenly or gradually, or may develop in the animals as they grow older. White-spotting also occurs on the bodies of these animals occasionally, but the rules of its inheritance show complications, and a pure spotted race has not been obtained.

IN March of 1917 the Board of Agriculture and Fisheries appointed a Committee to consider the fresh-water fisheries. Attention was directed to the use of coarse fish as food, to the development of the eel fisheries, and latterly to the improvement of the salmon fisheries. Two interim reports were issued, and as a result of these the Board made an Order in March, 1918, extending, as a war emergency measure, the season of capture of coarse fish by one month. This Order was revoked in the spring of 1919. A further Order removing restrictions on eel-fishing and abolishing the close season for pike was made in April, 1918, and revoked in October, 1919. Dealing with the eel fisheries, the Committee recommended that the factory on the Severn owned by the German Fisheries Union should be taken over, and, "after prolonged negotiations," this was done. The factory exported some five millions of elvers annually to Germany before the war. Arrangements were made to carry it on, and in 1918 and 1919 about 2½ millions of elvers were distributed throughout this country. The Committee hopes this work may be continued regularly. In its final report, now published, practical methods of eel cultivation are dealt with, and the necessity for investigation into the biology of fresh-water fishes in general is discussed. Recommendations are made with regard to the pollution of rivers, improvements of the latter as breeding-grounds, and the consolidation of the law as to fresh-water fisheries. Practical suggestions for the cultivation of carp are given in an appendix.

MR. W. B. WRIGHT, of the Geological Survey of Ireland, has made "An Analysis of the Palæozoic Floor of North-East Ireland, with Predictions as to Concealed Coalfields" (Sci. Proc. R. Dublin Soc., vol. xv., No. 45, 1919, price 1*s*. 6*d*.). Mr. Wright accompanies his careful reasoning as to the synclines and anticlines produced by the Armorican and later foldings by a coloured geological map showing the intersections of two systems of folds, and therefore the probable domes and basins. He relies much on the repetition of similar fold-features in the same area during successive geological periods—that is, on the principle of posthumous folding on which R. A. C. Godwin-Austen based his prediction of the Dover coalfield. It is no secret that the deep boring put down recently by the Ministry of Munitions on the west shore of Lough Neagh in accordance with the arguments of Mr. Wright has more than proved his main contention, the Carboniferous rocks, on the line of the Armorican syncline of Central Scotland, having been carried down by Cainozoic sinking to depths completely unexpected.

THE issue of the *Revue scientifique* for February 14 contains Prof. G. Friedel's opening address on his installation in the chair of mineralogy at the University of Strasbourg. Prof. Friedel, himself an Alsatian by birth, looks forward to the development of research in a university that will never become the slave of politics or the mere servant of industrial ideals. He says finely: "La science n'est pas la servante de l'industrie, elle en est la mère." His address deals with the insight given by the use of X-rays into crystalline and molecular structure, and he describes the work inspired by Laue, of Munich, in 1912 as "la plus belle assurément et la plus riche en promesses de la cristallographie récente." In the developments made by Sir W. H. and Prof. W. L. Bragg he perceives the end of our conception of the existence of molecules as such within a crystal, and a realisation of the crystal as one enormous molecule, in which the grouping of the atoms does not permit of a division into similarly constituted particles corresponding with the molecules of the chemist.

WE have received from Koninklijk Magnetisch en Meteorologisch Observatorium, Batavia, the volumes of rainfall records in the Dutch East Indies for the years 1915, 1916, and 1917 (Regenwaarnemingen in Nederlandsch-Indië). The records are remarkably complete, and comprise data from several thousand stations scattered throughout the islands. There is no discussion of the data, but the volume for 1915 gives the mean of more than three hundred stations for the period 1879 to 1915. The same volume gives useful notes on the position and equipment of the various stations.

THE Koninklijk Nederlandsch Meteorologisch Instituut has published the first part of an oceanographical and meteorological folio atlas of the Atlantic Ocean under the editorship of Dr. E. van Everdingen, director of the institute. The present part covers the months of December, January, and February, and is based on observations from 1870 to 1914. It follows the lines of the previous work on the Indian Ocean, and utilises mainly the observations of Dutch vessels, but these are supplemented by data from the Meteorological Office, London, and the Deutsche Seewarte. Maps for each month show the distribution of wind, currents, sea- and air-temperature, cloudiness, and floating ice. The volume of data which was to accompany the atlas has been delayed in publication.

THE current (April) part of the Proceedings of the London Mathematical Society is of melancholy

interest because it contains the conclusion of the late E. K. Wakeford's paper on canonical forms. The paper is remarkable for its generality and the simplicity which it gains by the use of the theory of apolarity. Moreover, certain results follow almost intuitively from known geometrical facts, *e.g.* the general ternary quartic cannot be expressed as the sum of five fourth powers, *because* the square of the conic through five points may be regarded, in this connection, as a quartic with double points at all of them. This example is interesting historically, because the original (and different) proof of the theorem in question was one of the first to show the untrustworthiness of the method of counting constants. Wakeford's premature death will be deplored by all who can appreciate the brilliance and originality of his work.

THE April issue of the Journal of the Röntgen Society contains the communication made to the society at a recent meeting by Prof. E. T. Jones on the action of the induction coil. By means of an electrostatic oscillograph Prof. Jones has investigated the effects on the potential of the secondary of the coil, both on open circuit and when connected to an X-ray tube, of changes in the capacity of the condenser shunting the break, and in the degree of coupling between the primary and secondary of the coil. He finds that the effects correspond closely with those to be anticipated on the theory that in the secondary on open circuit the potential after break consists of two component waves, which begin in opposite phase and have amplitudes inversely proportional to their frequencies. He considers that induction coils can be further improved by investigating and reducing the losses in the iron cores of the coils, by introducing interrupters which will break stronger currents without such large capacities in parallel with them, and by determining the best method of adjusting the coupling between the primary and secondary, either by alteration of their relative lengths or widths or by other means.

A VERY interesting example of the progress which has taken place during recent years in electric power supply is presented in a paper by Mr. J. S. Watson read on April 30 before the North-East Coast Institute of Engineers and Shipbuilders, in which he gave a brief historical sketch of the development of the generating stations of the Newcastle-upon-Tyne Electric Supply Co., the principal pioneer of electric power supply on a large scale in this country. Dividing the twenty-nine years of this company's activity into stages, Mr. Watson traced the progress from a small station with 2400 kw. in 200-kw. units to the latest addition, the Carville "B" station, with its five 10,000-kw. turbo-generators. Among the many important features referred to is the gradual decrease in steam consumption per kw.-hour from 28·5 lb. to 10 lb. An equally interesting comparison lies in the plant capacity per square foot of floor-space occupied, which is 15 kw. as against 0·3 kw., and other figures showing gain in economy are those of kilowatt capacity per man employed in the station—633 kw. and 141 kw. respectively. These improvements are attributable mainly to increases in boiler pressure, steam temperature, speed of revolution and size of unit, and to more complete utilisation of labour-saving appliances. Another no less important feature of the scheme is the running in parallel with the steam-driven stations of "waste-heat" generating plants at various points on the network utilising on a considerable scale by-product energy from coke-ovens and blast-furnaces.

IN a paper on the economics of the petroleum industry read recently by Mr. R. S. Dickie at the Imperial College of Science and Technology, there appears a series of well-justified criticisms relative to the geological, chemical, and engineering procedure of the producing companies. Such subjects as the proper spacing of well-sites, the economical utilisation of fuel by the provision of heat and cold interchangers, the preposterous waste in the current use of boiler-stills, the insufficiency of our present knowledge of lubrication and lubricating oils, the need for research on blended motor-fuel, and the possibilities of recovering valuable components from the crude oil by methods other than distillation were briefly touched upon. Among the more interesting statements made is the following: The greatest producing well is No. 4 Potrero del Llano (Mexican Eagle Co.), which ran wild for ninety days, flowing at the rate of 100,000 barrels per day. In the eight years of its life it produced 100,000,000 barrels of oil (1 barrel = about 45 English or 50 U.S.A. gallons).

WE have received from Messrs. A. Hilger, Ltd., 75A Camden Road, N.W.1, an attractive catalogue of their well-known wave-length spectrometer with high resolving power accessories, including the Lummer-Gehrcke parallel plate, the Fabry and Perot etalon, and the Michelson echelon diffraction grating. At a time when the structure of spectra is receiving so much attention from physicists it is good to know that a British firm can still assist in supplying the very necessary "munitions" in the form of efficient scientific apparatus. As is well known, this firm has been able very largely to control the effects of lack of homogeneity in glass by interferometer methods, which should considerably improve the performance of such instruments.

READERS of NATURE in search of book bargains should obtain and consult Catalogue No. 187 just issued by Messrs. W. Heffer and Sons, Ltd., Cambridge, in which some 331 books in new and perfect condition are listed at greatly reduced prices. Among the works relating to science we notice the "Scientific Papers" of Prof. J. C. Adams; sets in different bindings of "Biologia Centrali-Americana," also separate sections of the work; Prof. J. Stanley Gardiner's "The Fauna and Geography of the Maldive and Laccadive Archipelagoes"; Hagen's "Atlas Stellarum Variabilium"; Hewitson's "Exotic Butterflies" and "Illustrations of Diurnal Lepidoptera"; Leech's "Butterflies from China, Japan, and Corea"; and a set of "The British Bird Book," edited by F. B. Kirkman.

Our Astronomical Column.

A BRIGHT FIREBALL.—A splendid meteor was seen on May 9 at 9h. 10m. G.M.T., from Bristol, Cardiff, London, Weston-super-Mare, and other places. Special interest attaches to the object, for it appears to have descended to very near the earth's surface, if, indeed, it did not actually fall to the ground. The meteor traversed a path of about 60 miles in $5\frac{1}{2}$ seconds, and fell from a height of 54 to 12 miles. Combustion occurred over Radnor Forest, and the meteor apparently disappeared over a point 10 miles east of Barmouth. If the object was enabled to travel in a compact form about 15 miles further, it must have alighted on the ground in the region some ten miles south of Bangor, Carnarvonshire, but no intimation has yet been received that a meteorite has been found, or was seen to fall, there.

CONJUNCTION OF MERCURY WITH ϵ GEMINORUM.—Mr. A. Burnet, of Oxford University Observatory, makes a special study of occultations of stars by planets. He now points out a close approach of Mercury to the third-magnitude star ϵ Geminorum on June 11. The position of the star is R.A. 6h. 39m. 1·73s., N. decl. 25° 12′ 33·8″. Mercury is in the same R.A. at 9h. 7m. G.M.T., 14″ south. The semi-diameter and parallax are 2·9″ and 7·7″, so that an occultation will not happen at any part of the earth. The hourly motion of Mercury is +19·4s., S. 55·8″. Hence conjunction in declination occurs at 8h. 52m. Micrometer measures of the differences of R.A. and declination of planet and star will be of value, especially as Mercury is a difficult object to observe on the meridian. The sun sets in London at 8h. 14m., and Mercury at 9h. 50m. The times throughout are given in G.M.T., not summer time. It is rather unfortunate that the date coincides with that of the Royal Astronomical Society's meeting, as that will prevent some astronomers from observing it.

LONGITUDE BY WIRELESS TELEGRAPHY.—This subject was discussed at the geophysical meeting at the Royal Astronomical Society on May 7. Prof. Sampson, Astronomer-Royal for Scotland, pointed out that wireless telegraphy supplied the long-sought desideratum of signals that could be received simultaneously over the greater part of the earth's surface; in the past eclipses of the moon or Jupiter's satellites, lunar distances and occultations had been employed, but the new method gave far higher accuracy. He formulated a scheme in which three observatories at longitudes some 120° apart, or, if preferred, four observatories 90° apart, should each receive the signals of suitably placed wireless stations and note their local time in the usual manner by meridian observations. The method would determine both the longitudes of the stations and the periodic errors in the assumed clock-star places, since different clock-stars would be on the meridian of each observatory at the time of each signal. No extreme accuracy is called for in the time of sending out the signal, since the method is wholly a differential one. Interchange of observers is not contemplated; this has hitherto been the practice in longitude determinations, but the new method contemplates using the ordinary observations with the standard instrument of each observatory for a considerable period. There will thus be several observers, and if the travelling-wire method is adopted very little error will be introduced by personal equation. Plans are already far advanced for connecting Greenwich with Sydney in this manner.

A demonstration was given of the method of recording the wireless signals on a chronograph by the use of a Fleming valve. The ticks of a chronometer, transmitted by a microphone attached to the glass, were simultaneously recorded. The chief difficulty was stated to be not the weakness of the transmitted wireless signal, but the frequent confusion produced by atmospherics.

Periodicity in Weather and Crops.

IT is generally understood that the principal source of terrestrial weather changes is to be found in solar radiation. Inasmuch, therefore, as the yield of crops depends very largely on the weather, it is quite natural to assume that any periodicity in the solar radiation is likely to be reflected in the world-harvests and the price of food. Many investigations have had for their object the testing of a direct correlation between solar activity, as evidenced by sun-spots, and such terrestrial phenomena as the Indian monsoon in regard to drought and famine. The mechanism of world-weather is exceedingly complex, but progress is steadily being made in elucidating the cause of the numerous departures from obedience to any simple general law.

The next step, after comparing terrestrial phenomena with the known sun-spot period, was to analyse various sets of data in search of unknown periodicities, and Prof. Turner, for example, goes so far as to connect what he calls "chapters" of meteorological history with the movement of the earth's pole that produces latitude variation. There is, however, one very great difficulty in fixing any period the physical basis of which is unknown, and that is the incommensurability of all the suggested periods with that of the earth's revolution round the sun. It is obvious that a dry period occurring exactly at sun-spot maximum, for example, if such a phenomenon should be persistent, and if, which is another difficulty, the sun-spot maximum were an exact predictable moment, would have a totally different influence on the harvest according to the time of year at which the drought occurred. The effect would also be quite different in different parts of the world, notably on the two sides of the equator.

On Wednesday, May 12, Sir William Beveridge, Director of the London School of Economics and Political Science, delivered a lecture on the subject of a hitherto unrecognised periodicity in the weather and the crops. From the *Times* report of the lecture we gather that he rather discredits the "sun-spot" influence, at least in the form advanced by Prof. Jevons nearly half a century ago, and produces ostensibly consistent evidence in favour of a period of $15\frac{1}{4}$ years during the past three centuries. The argument rests upon historic records of poor harvests, of Indian famines, of tropical droughts and equally disastrous wet summers in higher latitudes, and also to a great extent upon official statistics of food prices.

There is no indication in the report that attention was paid to such obvious matters as war and plague, which would have an enormous effect on prices. The meteorologists of the next century will not, we hope, attribute the high prices under which we are now suffering to a periodic meteorological influence. Sir William Beveridge has succeeded in setting forth a list of dates at approximately equal intervals, and claims that every one corresponds to a period of high prices. He admits that there were other times of similar conditions not belonging to the series he claims to have discovered, and he also allows an occasional uncertainty of something less than five years, but he warns us to expect most unseasonable weather, bad harvests, and high prices, with possible famines, in one or more of the years 1924, 1925, and 1926.

From the summary of the evidence produced it is quite possible to extract some comfort. Sir William Beveridge's appeal to the barometer makes it clear that he regards a low mean annual pressure as a direct indication of bad harvests, and points to the years 1878, 1893, and 1909 as the three years of lowest pressure in a forty-year period over the greater part of the habitable globe. It is, on the face of it, practically impossible that the pressure over the whole earth should vary from year to year; so perhaps we are to assume a higher selective pressure over the ocean areas in such years. In any event, we were very fortunate in this country in 1893 with a glorious summer, shared also by France, in spite of the world-conditions. There is another aspect which must not be ignored, and that is the physical basis on which the period depends. The lecturer contented himself with suggestions of a combination of periods of shorter length, hinting that 15⅓ years is a sort of least common multiple of two or more of these. The actual figures given are, however, singularly unconvincing. Sir William Beveridge mentions a meteorological period of just over five years, without any details in support of it, and couples this with "the important 2¾-year cycle." Is this a period in itself, or is it merely one of the harmonics of the 11-year sun-spot period? He says eleven of these make two of his 15⅓-year periods; so if the 2¾-year period is really "important," his new one should be 30¾ years. What *is* apparently important, as we remarked before, is the 12-month period, and this would indicate 46 years as a super-period, but there is no indication of any specially bad harvests at every third period in his table.

Sir William Beveridge's forecast for 1924–5–6 is given with some diffidence, showing that he is not too confident of the reality of the period, and it is not likely that he has made much impression on the devotees of the sun-spot period, which has been claimed to show direct correlation with such different phenomena as the price of wheat and the number of fellows of the Royal Astronomical Society.

One last question we might raise is: Does fine weather necessarily mean lower food prices, considered in the light of the suggestion that strikes and labour unrest are generally regarded as fine-weather phenomena?

W. W. B.

The National Food Supply.

SIR DANIEL HALL, in the first of his three recent Chadwick public lectures on "Gardening and Food Production," dealt with the national food supply and the possibility of self-support. According to the values obtained by a committee of the Royal Society for the five-year period prior to the war, only 42 per cent. of the total food supply consumed in the United Kingdom was produced at home. At the beginning of the nineteenth century the country was practically self-supporting, but since that time the population has greatly increased, while the productivity has decreased. In 1872 there were 14 million acres under the plough in England and Wales, but by 1914 nearly 4 million acres of this land had been put down to grass. Grass land is comparatively unproductive of food as compared with arable land, for, according to Sir Thomas Middleton's calculation, 100 acres of arable land in this country normally produce food that will maintain eighty-four persons, whereas the same 100 acres under grass will maintain only fifteen to twenty persons. The great difficulty is that arable land requires much more labour than grass land, and farmers naturally refrain from ploughing up their land when the cost of labour has risen very much more than have the prices of the produce. In 1917–18 another 2½ million acres were added to the acreage already under the plough, but the food crisis is not yet over. It is essential that we should increase our productivity, and to attain this end we must agree to pay the prices necessary to make arable farming reasonably profitable to the farmer. Moreover, the population will have to change its habits and eat more bread, potatoes, etc., than meat, while pork will have increasingly to replace the more expensive animal foods.

The second lecture was concerned with the development and uses of allotments. The history of allotments appears to go back to a very early date; for from the time of Henry III. onwards there are statutes dealing with pieces of cultivated land of the allotment type. The first period of active growth of the allotment scheme was in the nineteenth century, when the industrial system and the large towns developed. A noteworthy example is the still flourishing group of allotments started by the late Sir John Lawes on his Rothamsted estate, in connection with which a club-house for the use of the allotment-holders was built as early as 1857. Without doubt the greatest extension of the allotment movement occurred during the years 1916 onwards, when the country was threatened with a serious food shortage. At the present time it is estimated that about one million allotments are in use. The typical allotment of one-sixteenth of an acre is rarely capable of providing all the potatoes and vegetables needed by an ordinary small household, but when a million of such allotments are considered, it is clear that they do bring about a marked saving in the national food bill. Unfortunately, the typical allotment is not always cropped to the best advantage, but it is hoped that this will be improved through the publication of a detailed scheme for allotments by the Ministry of Agriculture. In dealing with fertilisers the lecturer pointed out that many allotments are deficient in humus, and must be supplied with stable manure in addition to artificial fertilisers. Town-dwellers are faced with further difficulties over the tenure of their allotments, but it is hoped that all building schemes in the future will provide for a reasonable amount of allotment land.

"Social and Hygienic Conditions Respecting Gardens and Allotments" provided the subject for the third of Sir Daniel Hall's lectures. Under this heading was discussed the extreme importance of "vitamines," of which three at least have been found to be present in food. These vitamines occur mostly in living plants, although they are found also in certain animal foods. They are essential for the healthy development of human beings. In this connection appears one of the great values of allotments, for by their means a large number of people are provided with fresh vegetables containing the all-important vitamines, without which various diseases are liable to occur. The lecturer next dealt with the social value of allotments. Passive amusements, such as picture palaces, etc., fail to satisfy completely one's need for amusement, but there is enormous satisfaction in growing things; moreover, some of our best varieties of flowers and vegetables are the result of the efforts of working-men, who found much to interest them in the allotments which provided a welcome diversion from work that was often monotonous and carried out under unpromising conditions. The growth of the allotment movement will surely put men on a sounder economic basis, in addition to providing an active interest in life and to ensuring the better health of their families.

The Research Associations.

NOTHING could be more satisfactory than the account that Dr. A. W. Crossley gave on Friday last to the Conference of Research Associations of the constitution and methods of the British Cotton Industry Research Association, of which he is director. It embraces every activity that contributes to the production and utilisation of cotton, and represents more than 95 per cent. of the firms engaged in the industry. Among its members are some of the Labour leaders, and these take the keenest interest in its work. It aims to obtain, in the first place, more exact knowledge of the chemical and physical properties of the fibre and the scientific facts which lie at the base of the processes employed; for it is considered that it is only in this way that the true solution of the problems which present themselves can be assured. It is to be hoped that the same broad and scientific spirit may animate all the associations that have been formed under the Department of Scientific and Industrial Research.

It appeared to be generally agreed that one of the most important conditions of the success of the movement was its close association with the universities and colleges where scientific research has hitherto been mainly carried out. It is to them that research associations and the research departments of private firms must look for their supply of science workers, and it is obviously important that those who are engaged in preparing men and women for the task of industrial research should be acquainted with the lines on which it is carried on. It is for this reason to be desired that the scientific staffs of these institutions should take their share in the technical research required by our industries, and it is a matter of congratulation that the Imperial College of Science and Technology has already led the way in this direction. Lord Crewe, who presided, referred in this connection to the "industrial fellowships" established at Pittsburgh and elsewhere in the United States to facilitate the investigation of technical problems. The work is carried out in close co-operation with the universities, and at the joint expense of the manufacturers concerned and of the endowment.

The question of the publication of the results of industrial research presents serious difficulties. As Dr. Crossley remarked, those employed upon it must keep in close touch with those engaged in pure research, on whose conclusions their work is based, but they cannot be always taking without giving something in return. He urged that a large proportion of the work carried out should ultimately be published even if for commercial reasons it had to be held back for several years; and Dr. Lawrence Balls reminded the conference that the stimulus of the prospect of future publication was required to secure the accurate record of the data obtained in the course of a research.

Not less important are the closely allied questions of the remuneration and superannuation of the scientific workers employed by the associations. This was discussed by Mr. J. W. Williamson in an interesting paper. He came to the conclusion that under present conditions 400*l.* per annum is the minimum that should be offered to a science graduate who has already had two or three years' training in research. He pointed out that a post under a research association did not afford the same security of tenure as one at a university. The desirability of extending to the staffs of research associations the federated superannuation system for universities was acknowledged on all sides.

J. W. E.

Solid Lubricants.

ALTHOUGH the report of the Lubrication Committee has not yet been issued, a "Memorandum on Solid Lubricants," prepared for the Committee by one of its members, Mr. T. C. Thomsen, has recently been published (Bulletin No. 4 of the Department of Scientific and Industrial Research Advisory Council). This pamphlet of twenty-eight pages contains a digest of the existing knowledge in this branch of the subject, and will be found most useful to all engineers and users of machinery. The solid lubricants referred to are natural and artificial graphite (which are by far the most important), talc, mica, and such substances as flowers of sulphur, white lead, etc., which are occasionally used for curing hot bearings. The greater part of the bulletin is concerned with graphite, and although there is not much matter which is new, there is a great deal of information which will be of interest to many users of lubricants. The action of solid lubricants and the conditions under which they can be usefully employed are clearly explained.

The natural graphite used for lubrication is usually of the flake variety, and varies in the size of its particles from 1/10 in. to less than 1/200 in. The lubricating graphite produced artificially is amorphous. It is ground even finer than the natural graphite, and by chemical treatment is further reduced to particles of colloidal dimensions and sold under the trade-names of "Aquadag" and "Hydrosol" when in admixture with water, and "Oildag," "Oleosol," and "Kollag" when in admixture with oil. Analyses of the different varieties of lubricating graphites are given in the pamphlet, and it is seen that some are almost chemically pure carbon, whilst others contain mineral matter in variable proportion. Solid lubricants are applied dry in cases where for special reasons it is inadvisable or impossible to use liquid or semi-solid lubricants, but they are usually employed in admixture with oil or as an ingredient of greases. When mixed with oil ordinary graphite settles out, owing to its high specific gravity. Colloidal graphite does not settle so long as the vehicle remains neutral, and is carried with oil through the finest orifices, even through worsted trimmings, but it has the disadvantage of being easily caused to coagulate in presence of acid or alkali.

"Oildag" and "Aquadag" have been on the market for a number of years, and the experiences of users of these and other forms of graphite which Mr. Thomsen has collected for general information will be found of considerable value. Perhaps the most interesting experience is that of Mr. E. W. Johnston, who has successfully employed "Aquadag" as a cylinder lubricant and eliminated all the trouble caused by the presence of oil in condensed steam. Experiments made at the National Physical Laboratory showed that the addition of "Oildag" to mineral lubricating oil was advantageous where solid friction occurred, as in worm gear, but quite as good results were obtained with natural flake graphite, so that the lubricating value of graphite seems to depend upon its chemical purity, and the special advantage of the colloidal graphite is due to its property of remaining naturally suspended in the liquid medium without requiring to be stirred constantly by artificial means. The remarks on the use of graphite in internal-combustion engines, in the lubrication of ropes and chains, and in metal-cutting and wire-drawing will be found of great interest and practical use.

All who are interested in lubricants should obtain a copy of this pamphlet, which can be purchased through any bookseller for sixpence.

L. A.

Greek Science and Philosophy.

ON Wednesday, May 12, Dr. C. Singer delivered his inaugural address as lecturer in the history of medicine at University College, London. Sir Robert Hadfield presided over a large and distinguished audience. After alluding to the neglect of the history of science in this country, Dr. Singer referred to the organised effort now being made by Dr. Wolf and others to remedy it at University College. The institution in which Augustus De Morgan spent the whole of his active life was a peculiarly appropriate place for such an experiment. The history of science was a necessary element in any curriculum that sought to give a view of the mental history of the human race. Turning to the various stages through which science has passed, Dr. Singer made some interesting comparisons between the science of the ancient East, the science of Greece, and modern science. Among the characteristics which distinguished Greek science from Oriental science and allied it to ours were the individuality and eponymity of its discoveries, as distinguished from the anonymous thought of preceding civilisations, which always appeared as a social rather than as an individual product. Another and more important feature of Greek thought was the conviction of the reign of law, the idea that order rules in Nature. This belief, almost an article of faith with the Greeks, has been justified more and more with the advance of natural knowledge. On the other hand, Greek science differed from ours in various ways. The most obvious difference was the intimate relation between Greek science and Greek philosophy. This was due to the fact that Greek science was originally a department of Greek philosophy. The divorce between our science and philosophy had many advantages, but also some drawbacks. Another important difference between Greek and modern science is to be found in the method of record. The Greeks were interested in results rather than in methods, and almost always neglected to give an account of their methods. As a consequence, their results cannot be relied upon, and, except by hard research, we can get no glimpse of their methods of working. The mathematical group of sciences, however, formed an exception in this respect. In these the Greeks recorded their methods as well as their results.

Life-history of the Periwinkle.

UNTIL 1908 the life-history of the common periwinkle, *Littorina littorea*, L., was unknown. In that year Dr. W. M. Tattersall published a brief announcement of some investigations made that included the discovery of its ova. He reserved a more detailed account until further observations and researches could be carried out, but this proved impracticable, and Dr. Tattersall has now issued the notes of his work so far as it went (Department of Agriculture and Technical Instruction for Ireland (Fisheries Branch), Scientific Investigations, 1920, No. 1, pp. 11, 1 plate), being largely instigated thereto by the publication in 1911 of a paper on the same subject by MM. Caullery and Pelseneer. From Dr. Tattersall's account it appears that the breeding season lasts from the middle of January to June, and the pink eggs are enclosed singly or in pairs (sometimes three and exceptionally four) in small, curiously shaped, transparent capsules resembling a soldier's "tin" hat, the eggs occupying the crown. These capsules are unattached, and vary from 0·6 to 0·9 mm. in diameter, the eggs being from 0·15 to 0·16 mm. Segmentation is completed during the first day, and at the third day the circumoral ring of cilia is complete and the embryo begins to rotate. At the sixth day the embryo breaks out from the capsule and swims freely about in the water. The chief food of *Littorina littorea* appears to be the hyphal hairs of *Fucus serratus* and allied seaweeds, and the animal swallows indiscriminately the diatoms and other microscopic organisms clinging to the seaweed. The climbing habits of these molluscs suggested to the author the possibility of establishing "farms" for their more easy collection for the market. Experiments were made by erecting stakes in their intertidal haunts, but, though the snails of all ages would ascend, they seemed incapable of retaining their hold save in calm weather, hence the farming had to be abandoned. In conclusion, the author advocates the grading of the winkles into sizes before dispatching them to market, using two sieves of $\frac{3}{4}$ in. and $\frac{5}{8}$ in. respectively, and rejecting all that pass through the smaller as unmarketable.

The Royal Society Conversazione.

THE first of the two annual conversaziones of the Royal Society was held at Burlington House on Wednesday, May 12, when the president, Sir Joseph Thomson, received a large company of fellows of the society and other workers of distinction in the scientific world. As is usual upon such occasions, many exhibits of recent methods and results of investigation were displayed, and much interest was taken in them. Mr. A. A. Campbell Swinton gave a most successful demonstration and exposition of wireless telephony with apparatus supplied by the Marconi Wireless Telegraph Co., Ltd. Gramophone records and musical instruments played at the company's works at Chelmsford were loudly reproduced in the meeting-room of the society. The apparatus used consisted of an amplifying detector and note magnifier, to which was connected a loud-speaking telephone enabling speech to be heard distinctly over the whole ground floor. The aerial consisted simply of a frame 3 ft. square, wound with a few turns of wire, and placed on the lecture-table in the meeting-room. The subjoined descriptions of most of the exhibits, arranged so far as possible in related subjects from man to machine, are abridged from the official catalogue:—

Mr. M. C. Burkitt: (1) Tracings of prehistoric rock engravings from the shores of Lake Onega, North Russia, the only site in Russia west of the Urals where prehistoric engravings occur. (2) Palæolithic stone implements from North Africa, showing that there is a series comparable in general form with the regular sequence in France and Britain.

Mr. S. H. Warren: Specimens from a factory of Neolithic stone axes at Graig-lwyd, Penmaenmawr. The axes were made from the scree which fell down the mountain-side from a line of crags formed of the fine-grained (chilled) margin of the Penmaenmawr intrusion. Axes are found in every stage of manufacture, discarded on account of breakage or unsatisfactory shape, the most frequent fault being excessive thickness of blade. Palæolithic resemblances are abundant and striking.

Mr. L. Treacher: A large Palæolithic implement from the Gravel at Furze Platt, near Maidenhead. The gravel in which this implement was found has also yielded a very large number of palæoliths, mostly belonging to the Chellean type, although a few Mousterian flakes have been found. The surface level is

about 140 O.D., being 20 ft. lower than that of the Boyn Hill terrace in the neighbourhood.

Mr. Herbert Bolton: Enlarged photographs of fossil insects from the British Coal Measures. The first recorded fossil palæozoic insect from any country was discovered in the Coal Measures of Coalbrookdale in the early part of last century. In 1908 only twelve additional types from Great Britain had been made known. Mr. Bolton's researches during the last ten years have revealed the fact that at least fifty distinct types had lain unrecognised in various museums and private collections. The photographs exhibited were made by Mr. J. W. Tutcher.

Dr. W. K. Spencer: Palæozoic starfish and their habits. Recent work by the Danish Fisheries Board upon the habits of recent forms throws considerable light on the mode of life of the fossil starfish. Recent starfish can be divided into (1) starfish, carnivores, and (2) brittle starfish, detritus feeders living on vegetable remains in the mud on the sea-bottom or on very young marine animals. Both these series of forms are modified for their respective mode of life. The exhibit showed that both classes of forms were present in the palæozoic rocks, and that some of the forms from the very old rocks were strikingly similar in mode of life to those of the present day. Forms which are transitional in structure between the two series were also shown.

Dr. F. A. Bather: Stalked Echinoderms with a horizontal habit of growth. In a normal stalked Echinoderm the stalk, body, and five arms are symmetrical about the long axis, which is vertical, and the waste products are carried away from the vent at the upper end. But all the Cystids found in the Upper Ordovician starfish bed of Girvan, Ayrshire, have a body flattened in the plane of the stalk, and this shows that the long axis was stretched horizontally. Extreme modification for this mode of life is reached in three different ways by three genera of diverse origin: Dendrocystis, which floated, with its stalk attached probably to seaweed; Pleurocystis, which was possibly attached, but rested its body on the sea-floor; and Cothurnocystis, probably free, with its body resting on the sand by short legs. Cothurnocystis had no arms, but from thirteen to forty-two mouth-slits.

Mr. R. D. Oldham: Model to illustrate an hypothesis of the origin of mountains. If the variation in density, and consequently in bulk, of the matter underlying mountain ranges is also the cause of the surface elevation, and if the outer crust is possessed of a considerable degree of strength and stiffness, resting on material of a more yielding character, systematic departures from complete equivalence of surface elevation and compensation would result. The model is intended to visualise this.

Mr. A. V. Hill: Thermopiles for investigating the thermal or the thermo-elastic properties of muscles. When a muscle is stimulated, heat is produced in four separate stages: (*a*) in the development, (*b*) in the maintenance and (*c*) in the disappearance of the mechanical response, and (*d*) in the processes of oxidative recovery. This heat-production is recorded by employing delicate insulated thermopiles and a sensitive galvanometer with photographic recording.

Prof. E. Mellanby: The effect of an accessory food factor (vitamine) on: (1) The production of rickets in puppies. Soft bones and other signs of rickets are produced in puppies (five to eight weeks old) when fed on diets unbalanced in that they contain too little of an accessory food factor (vitamine)—probably fat-soluble A. (2) The development of the teeth in puppies. Diets deficient in a vitamine, possibly fat-soluble A, produce teeth defectively calcified and more or less irregularly placed in soft jaws.

Mr. Julian Huxley and Mr. Lancelot T. Hogben: The relation of the thyroid to metamorphosis. The exhibits illustrated (1) acceleration of frog's metamorphosis by thyroid-feeding; (2) metamorphic changes in the axolotl induced by iodine; and (3) metamorphosis of Amblystoma by thyroid-feeding with a control.

Prof. R. Newstead: Samples of mite-infested flour. Flour which is heavily invested with mites (chiefly *Aleurobius farinae*) is certainly ruined. It has a most unpleasant odour, and in the early stages becomes discoloured owing to the quantities of excrement with which it is charged. Prevention from attack may be secured by storing flour with a low moisture content, *i.e.* below 11 per cent. in the temperate zone and from 6–7 per cent. in the tropics.

Prof. G. H. F. Nuttall and Dr. D. Keilin: Hermaphroditism in ***Pediculus humanus***. The microscopic specimens illustrated hermaphrodites of intersexual type and included a complete series of forms from those of male type to those of female type, the co-existing characters of both sexes being present to a varying degree. The intersexual forms which occur among Pediculi in Nature are derived from the crossing of the races of *P. humanus*, *i.e. capitis* and *corporis*. Some of these crosses yield up to 20 per cent. of hermaphrodites.

Mr. J. E. Barnard: Photomicrographs obtained by means of ultra-violet light. It is well known that resolving power in the microscope is dependent on the N.A. of the objective and the wave-length of the light used. Decrease of wave-length results in proportionate increase of resolution, and this method opens up a promising field of investigation. There is the further advantage that biological preparations, particularly bacteria and other micro-organisms, are sufficiently opaque to ultra-violet light of suitable wave-length to render staining unnecessary. The result is that they can be photographed in the living state.

Dr. J. C. Mottram and Dr. E. A. Cockayne: Demonstration of fluorescence in Lepidoptera by ultra-violet radiation. The beam of ultra-violet rays is produced by means of a quartz mercury vapour lamp in a box with a window of the glass invented by Prof. Wood. This is transparent to radiation of wave-lengths lying between 3900 and 3100 A.V., but opaque to light. Only a small proportion of the Lepidoptera examined have proved to be fluorescent, and all of these are whitish or yellow in colour.

The Botany Department, Imperial College of Science and Technology: Recording porometer. This instrument records the rate at which air, under slightly reduced pressure, is drawn through the stomata (pores) into a glass cup fixed on the under-surface of the leaf. It thus gives a measure of the size of these pores. Every time a bubble of the air so drawn in escapes from the lower tube it momentarily makes contact between the mercury and a platinum wire; the current passing then moves the recording pen on the surface of the revolving drum.

The Cambridge and Paul Instrument Co., Ltd.: A new microtome. This instrument is designed on similar lines to the well-known Cambridge "rocking" microtome, but the object is in a much more convenient position for observation and orientation, and the microtome cuts plane sections in either paraffin or celloidin, and the design is suitable for freezing objects by ethyl chloride spray.

The Royal Geographical Society: Method of mounting panoramic views of wide angle. A photographic panorama of wide angle, made up from a number of separate pictures, gives a false impression

of the country if shown flat. The pictures should be enlarged to an equivalent focal length greater than the distance of distinct vision, and mounted in a polygon circumscribing a circle of radius equal to the focal length.

The Meteorological Office: New instruments and diagrams: (1) Land aneroid and sea aneroid. (2) Barometer with micrometric adjustment. (3) Two similar synchronous charts and the weather of the following fifteen days. (4) Normal weather on the Cairo to Cape route. (5) Charts of the average distribution of rainfall, cloudiness, and temperature over the northern and southern hemispheres in January and July. (6) Map of the annual rainfall in the English Lake District. (7) Records of the magnetic disturbance of March 23-24, 1920, and photographs of aurora for height-measurements. (8) Frequency of thunderstorms on the route between England and Australia and at selected stations in Africa and South America. (9) The flow of air over Kew Observatory, Richmond, during the last three years.

Air Ministry Laboratory: Apparatus for air navigation. (1) Four alternative methods for the quick solution of spherical triangles necessary for the obtaining of position lines from astronomical observations taken from aircraft: (*a*) The d'Ocagne nomogram. (*b*) A slide-rule based thereon. (*c*) The Veater diagram. (*d*) The Bygrave slide-rule. (2) Wimperis wind-gauge bearing plate, to enable the velocity and direction of the wind to be measured whilst in flight, (i) by flying on two courses and noting the drift angles, and (ii) by flying on one course and using a chronometer. (3) Capt. Weir's (Littrow projection) diagram applied to the purpose of obtaining position lines from W/T bearings.

The Admiralty Compass Department: (1) Two standard types of aircraft compasses. (2) Examples of aperiodic compasses for use in ships and aircraft. The aperiodic system adopted in these compasses is a result of the investigations of Mr. G. T. Bennett and the late Lt.-Comdr. C. Campbell.

Mr. E. A. Reeves: Apparatus for showing the existence of a true north and south directive force in the electricity of the atmosphere. This apparatus consists of a large glass bottle with an india-rubber stopper, from which is suspended by a fibre of unspun silk a gold-leaf paper indicator. The inner side of the stopper is covered with paraffin wax, and the bottle is coated inside and out with shellac varnish. The whole is mounted on a tripod stand. On a calm, clear day, when the apparatus is set up in a high open space and screened from the direct rays of the sun, it is found that after the paper is electrified by touching it with vulcanite rubbed on dry cloth, and left for some time, it will oscillate about evenly on either side of the true north and south line, or come to rest approximately in that direction.

Mr. C. V. Boys: (1) Noon reflector. The noon reflector is a very simple form of transit instrument intended to be set on a window-sill facing south and producing a pinhole-reflected image of the sun on the ceiling or opposite wall, from which the time may be obtained with an accuracy of about one second. (2) Azimuth declination time-chart. The azimuth declination time-chart is a graphic representation of the hour angle of the sun for all declinations at a particular latitude and azimuth from which the hour angle may be read with an accuracy of one-tenth of a second of time. This is for use with the noon reflector when set at some azimuth other than south.

The National Physical Laboratory: Oriented lustre of etched crystalline surfaces. The etched crystalline surface of metal is covered with a number of minute plane facets the orientation of which is uniform throughout each individual crystal, but varies from one crystal to the next. A beam of oblique light falling on such a surface is selectively reflected by these facets in such a way that the area of certain crystals appears uniformly and brightly illuminated, while other crystals remain dark. By illuminating such a surface by means of three separate beams of coloured light falling upon the crystals at various angles of incidence a striking effect is produced. Each crystal reflects into the eye of the observer a portion of one of the beams falling upon it at a suitable angle, and the various crystals consequently appear of different colours (Dr. W. Rosenhain and Mr. J. H. Haughton).

Messrs. Adam Hilger, Ltd.: Vacuum grating spectrograph for the extreme ultra-violet. A concave grating spectrograph, specially designed for the investigation of the Schumann and Lyman regions of the spectrum. No refractive substance (*e.g.* quartz or fluorite) is introduced, but the whole spectrum is obtained with one setting of the grating by the use of two slits. These are disposed in the end plate of the instrument, just above the plate-holder, which is cylindrical in form and provided with a plate for sealing purposes.

The Osmosis Co., Ltd.: Clays treated by electro-osmosis: Photomicrographs and specimens of articles made with osmosed clay. The phenomena of electrical osmosis, whereby matter in a very finely divided state is capable of being influenced by an electrical potential, have an important practical use in the purification of clays. Low-grade and discoloured china clays become usable as paper clays and pottery clays, and all china clays are improved in colour as a result of treatment.

Messrs. J. Crosfield and Sons, Ltd.: Synthetic products for perfumery. Synthetic perfumes of British manufacture were shown, most of which were formerly produced entirely in foreign countries. The manufacture was undertaken owing to the difficulty, in some cases impossibility, of obtaining such products during the war.

Mr. A. Mallock: Apparatus used in the determination of the variation of rigidity with temperature. The specimen to be tested forms part of a torsion balance, in which the restitutive couple is supplied by the torsion of a long thin wire, together with that of the specimen, the latter being in the form of a short wire or narrow strip about 2 in. long. The specimen and lower part of the balance can be immersed in a tube of fluid kept at any desired temperature. The periods of oscillation are automatically recorded for various temperatures, and the ratio of these periods furnishes the necessary data for determining the ratio of the rigidities. In making an experiment the oscillations are maintained continuously, the specimen being immersed successively in water at 100°, at room-temperature, in carbonic acid, in alcohol, and in liquid air.

Mr. C. R. Gibson for Mr. Joseph Goold: Experiments in rotational dynamics. The exhibit illustrated is a new development of Mr. Goold's earlier experiments in vibrating bars, the most remarkable of these being the vortex phenomenon demonstrated about a quarter of a century ago. The new experiments showed a rotational effect which is independent of the vortex phenomenon. A light clamp is fitted across the steel bar carrying an upright needle or rod, upon the free end of which is supported a light metal vane or "spinner." On setting the plate in vibration the spinner rotates with considerable energy. This rotation results from the interplay of two systems of vibration acting at right angles to each other. The following explanation is suggested by Mr. Gibson, who gave the demonstration: In one of the systems the bar vibrates between nodal lines which cross the width of the bar; this is termed a *normal* system.

In the other system of vibration the bar has a nodal line running along the longitudinal centre of the bar, while cross-nodes are also present; this class of vibration is termed a *dual* system. In the latter we may picture the sections of the bar on opposite sides of the central line to be out of phase with each other, so that one section is going upwards at the moment the other section is going downwards. This will give a slight rocking motion to the clamp, causing the free end of the needle to move to and fro in direction across the bar. Similarly, the bar is vibrating between the cross-nodes, so we may picture the sections divided by these to be upwards on one side of the cross-node and downwards on the other, thus giving a rocking motion to the needle in a direction lengthwise with the bar. These two motions (dual) combine to give the free end of the needle an elliptical motion; hence the rotation of the spinner.

The Hon. Sir Charles Parsons: Water-hammer cone demonstrating the destructive effect of collapsing vortex cavities. The apparatus consists of a hollow cone. At the small end is fitted a die-cap through which passes a hole of the same diameter as the small end of the cone. Between this cap and the cone thin metal plates are inserted. The cone is placed in water in the tank, allowed to fill with water, and then thrust quickly downwards, its mouth striking on to a rubber block at the bottom. The sudden arrest by the rubber block gives a high rate of relative acceleration of the water in the cone, producing momentarily a cavity at the apex, which, however, immediately closes again with a perceptible metallic hammering sound, and with sufficient pressure, due to the concentrated energy of the closing cavity at the apex, to puncture metal plates above 0·03 in. in thickness, indicating a pressure of 140 tons per square inch.

Mr. Edwin Edser: The concentration of minerals and coal by froth flotation. Many valuable minerals, particularly metallic sulphides, can be concentrated from low-grade ores by crushing these to a fine powder, mixing them with water, adding a small quantity of a suitable reagent, and agitating the mixture so that air is entrained in the form of fine bubbles. On allowing the mixture to come to rest, the bubbles carrying the mineral particles rise to the surface, and find a mineralised froth which can be removed. The barren rock (gangue) is not floated. Demonstrations were given of (1) the recovery of galena (lead sulphide) and blende (zinc sulphide) as separate products from Broken Hill ore; (2) the recovery of coal from waste dumps.

Sir Robert Robertson: Instrument for determining the pressure developed by detonators by Hopkinson's principle. This instrument, which was designed by Mr. H. Quinney at the Research Department, Woolwich, illustrated the quantitative measurement of the pressure of the blow delivered by a detonator according to the principle enunciated by Hopkinson. This principle depends on the separation of momentum into pressure and time. When the blow is applied to one end of a steel bar, a short length of the bar, attached by means of a faced joint to the other end, is thrown off as a result of the application of the pressure of the blow. The momentum of this short length (the "timepiece") is measured by catching it up in a ballistic pendulum. As the rate of transmission of the impulse in steel is known, the time taken for the pressure wave to pass twice the length of the "timepiece" is also known, and so the pressure can be deduced.

Prof. F. W. Burstall: Optic indicator for internal-combustion engines. An instrument for obtaining the power and the pressure in internal-combustion engines. The objects aimed at are to obtain accurate readings of the pressures up to 600 lb. per square inch and speeds up to 2500 revolutions per minute.

University and Educational Intelligence.

CAMBRIDGE.—Mr. E. A. Milne, fellow of Trinity College, has been appointed assistant-director of the Solar Physics Observatory.

The new professorship of physical chemistry is declared vacant.

It is proposed to make it possible for students to take the first M.B. examination before coming into residence on account of the greater facilities now provided in schools for the teaching of chemistry, physics, and biology.

The discussion on the syndicate's report on the relation of women to the University is fixed for October 14.

The Local Lectures Summer Meeting will be held from July 29 to August 18. The main subject of study will be the history, literature, and art of Spain, but courses in physical science (historical and biographical) and in elementary astronomy are being arranged in co-operation with the Association of Science Teachers. Further information can be obtained from the Rev. Dr. Cranage, Syndicate Buildings, Cambridge.

LIVERPOOL.—Dr. Charles Walker has been appointed associate-professor in cytology and lecturer in histology.

Mr. J. Wemyss Anderson, dean of the faculty of engineering, and associate-professor of engineering in the University, has been appointed to the recently established John William Hughes chair of engineering-refrigeration.

Messrs. Alfred Holt and Co., Ltd., of Liverpool, have contributed 15,000*l.* to the University Appeal Fund. The Association of West African Merchants and the African Section of the Chamber of Commerce, Liverpool, have decided to raise 12,000*l.* by voluntary contributions from their members to provide a chair of Colonial commerce, administration, and history at the University and to increase the endowments of the School of Tropical Medicine.

LONDON.—The following courses of advanced lectures will begin shortly:—Three lectures on "The Early Civilisation of Malta," by Prof. Th. Zammit (of the University of Malta), at University College, at 5.30 p.m., on May 20, 27, and 28; four public lectures on "High-frequency Alternators for Radio-Telegraphy," at the Institution of Civil Engineers, S.W.1, by M. Marius Latour (of Paris), at 5.30 p.m., on May 26, 27, 28, and 31; and four lectures (in French) on "Divers Modes de Dynamisme des Eruptions Volcaniques et les Phénomènes de Latéritisation," at the Imperial College (Royal School of Mines), by Prof. A. Lacroix, at 5 p.m., on June 14, 15, 16, and 17. Admission to the courses is free, without ticket.

ANNOUNCEMENT is made of the impending retirement of Mr. T. P. Gill, who has been Secretary of the Department of Agriculture and Technical Instruction for Ireland since it was established.

THE Regional Association, in co-operation with the Civic Education League, proposes to hold a meeting at Glastonbury from August 21 to September 11. The purpose of the meeting will be (1) to make a regional survey, rural and civic, of Glastonbury and its surroundings, and (2) to proceed, from the material so obtained, to a critical study of social life and institutions. Particulars may be obtained from Mrs. Fraser-Davis, hon. secretary of the Regional Association, 1A Lancaster Place, Belsize Place, N.W.3, or 65 Belgrave Road, S.W.1.

THE Sorby research fellowship has been awarded to Dr. F. C. Thompson, of the department of applied sciences of the University of Sheffield, for research into the constitution of the alloy steels. The fellowship, which is tenable for five years, is awarded by a committee appointed by the council of the Royal Society and the University of Sheffield from a fund bequeathed by the late Dr. H. C. Sorby. Dr. Thompson holds the degrees of Doctor of Metallurgy (Sheffield) and Bachelor of Science (London). He was a Carnegie research scholar of the Iron and Steel Institute, is a member of many bodies concerned with physical and metallurgical matters, and has published a number of papers on metallography and allied subjects.

THE Dr. Jessie Macgregor prize for medical science, of the Royal College of Physicians, Edinburgh, is to be awarded in July to the applicant who presents the best record of original work in the science of medicine, published or unpublished, but must not have been published earlier than three years prior to the date of award of the prize. The prize, which is of the value of 75*l.*, is open to women medical graduates of the University of Edinburgh, or to those who have taken the triple qualification and before being qualified studied medicine for at least a year in Edinburgh. Applications for the prize, with a record of the work of the competitor, must be sent to reach the Convener of the Trustees, Royal College of Physicians, Edinburgh, by, at latest, June 1.

THE Bureau of Education in India has issued a pamphlet by Mr. R. K. Sorabji entitled "Facilities for Indian Students in America and Japan." Mr. Sorabji warns students that it is unwise for anyone to visit the United States on an allowance of 50 or 60 rupees per mensem, even though the student may make some money in the vacations; he requires from 150*l.* to 200*l.* a year, of which he may earn 50*l.* The facilities for technical education and the cheapness of it may attract the student to Japan, but the candidates for admission to the colleges exceed the accommodation, and when a system of competitive examination is introduced, the youth trained in a Japanese school possesses greater advantages than the Indian. As is the case in the United States, the student will require an allowance of from 100*l.* to 150*l.* per annum, and as the teaching is given in Japanese he must acquire that language before he can derive any advantages from Japanese institutions.

Societies and Academies.

LONDON.

Royal Society, May 6.—Sir J. J. Thomson, president, in the chair.—R. H. **Fowler**, E. C. **Gallop**, C. N. H. **Lock**, and H. W. **Richmond**: The aerodynamics of a spinning shell. This paper deals with the motion through a gas or a body with an axis of symmetry and a spin about that axis. The range of velocities includes the velocity of sound in the gas. It has special reference to the motion of an ordinary shell through air under gravity. The problem is approached from the aerodynamical viewpoint. The force system imposed by the gas is analysed into its most important constituents by help of the theory of dimensions and by detailed wind-channel experiments. The general equations of motion are obtained in a vector notation, and reduced to tractable approximate forms in certain important special cases; in particular, when the axis of symmetry and the direction of motion of the centre of gravity nearly coincide. An approximate formal solution of these last equations is obtained, and the errors in the equations themselves and their solutions are shown to be negligible. The solutions obtained are submitted to the test of experiment, and the magnitude of the more important members of the force system determined numerically as functions of the velocity of the shell up to twice the velocity of sound. At the same time the main assumptions made in the analysis are verified. The experimental method used is to fire the shell through a series of cards. The shape of the holes left in the cards determines accurately the angular motion of the axis of the shell. From this the values of the chief components of the force system are deduced. One of the principal results is to determine accurately the spin required to render the shell stable at any velocity. The behaviour of the force components as functions of the velocity appears to be of scientific interest, and of obvious importance in technical ballistics.—Prof. W. E. **Dalby**: Researches on the elastic properties and the plastic extension of metals. This paper relates to a new type of load-extension diagram recorded automatically by an adaptation of an instrument already described to the society. The extension of the test piece is multiplied 150 times by the instrument. With this magnification, about $\frac{1}{1000}$ extension is shown on the negative, and the elastic line appears at a slope of about 60°. The shape of the elastic line can therefore be studied and the process of extension can be watched, so that stretching can be stopped at an assigned value and the load removed and then re-applied. The removal and re-application of the load produce a loop on the diagram, and several such loops can be described on each negative. Looped diagrams taken from metals commonly used were shown. Comparisons of these looped diagrams show that each metal is characterised by its elastic line and loops. A succession of plates was taken from a test piece of high carbon steel stretched almost to breaking. These plates set end to end give a procession of loops, and show that the loop area tends to a maximum. The questions of time-interval between the taking of loops and heat treatment between the taking of loops are examined in relation to loop area. It is shown that in the high carbon steel and alloy steel lapse of time has little or no effect in restoring elasticity, nor is the elasticity restored by boiling in water. New data relating to the strength of materials are given by these diagrams, viz.: (1) The area of the loop. (2) The rate of increase of the area of the loop. (3) The maximum area.—C. T. R. **Wilson**: Investigations on lightning discharges and on the electric field of thunderstorms. The investigations were carried out at the Solar Physics Observatory, Cambridge, by methods already described (Proceedings, 1916). Apparatus has been added to secure a photographic record of the readings of the capillary electrometer used in the measurements. Changes in the electric field which occupy less than a tenth of a second are recorded. The sudden changes produced in the potential gradient by the passage of lightning discharges recorded in 1917 were positive in 432 cases and negative in 279. The mean value of the electric moment 2QH (Q being the quantity discharged and H the vertical height through which this charge is displaced) of a lightning discharge is about 3×10^{16} e.s.u. × cm. or 100 coulomb-kilometres. The mean quantity discharged is of the order of 20 coulombs. The magnitude of the potentials attained in thunderclouds is of the order of 10^9 volts. The rate of vertical separation of charges in a thundercloud may amount to some coulombs per second, *i.e.* the vertical current through the cloud is of the order of some amperes. A thundercloud or showercloud may be regarded as an electric generator, capable of maintaining between

its poles an electromotive force of the order of 10^9 volts. It tends to maintain an electric current from the earth to the conducting layers of the upper atmosphere or in the reverse direction, according as its polarity is + or −. The difference which must exist in the conductivity of the air above showerclouds of + and of − polarity respectively, owing to the large difference between the mobilities of the negative and positive ions dragged out of the conducting layer by the field of the cloud, furnishes a possible explanation of the normal positive potential gradient at a distance from showerclouds. It is also shown that it will account for the prevailing negative sign of the potential gradients associated with showerclouds and for the preponderance of positively charged rain and positive lightning discharges, *i.e.* discharges which produce a positive change of potential gradient.—L. F. **Richardson**: The supply of energy to atmospheric eddies. Osborne Reynolds investigated the energy of eddies as a balance between income and expenditure. The income was the activity of the eddy stresses upon the corresponding rates of mean strain; the expenditure was by way of molecular viscosity. His theory refers to an incompressible liquid, but it is shown in the present paper that the same applies to an elastic fluid. In a gravitating atmosphere there is an additional channel for gain or loss, because the eddies act as thermo-dynamic engines, either producing or decreasing inequalities of temperature. They are, however, imperfect engines. It is shown that the activity contributed by the eddies by this process is

$$\frac{g}{\gamma p} c \frac{\delta\sigma}{\delta h} \text{ per volume,}$$

where g is the acceleration of gravity, γp the thermal capacity per mass, c the eddy-conductivity, σ the entropy per mass, and h the height. In the actual atmosphere this activity is ordinarily an expenditure by the eddies. By balancing it against their income a criterion of turbulence is obtained. Some observations of the quiescence of wind on a clear evening tend to confirm the theory.

Geological Society, May 5.—Mr. G. W. Lamplugh, vice-president, in the chair.—S. H. **Warren**: A natural "eolith" factory beneath the Thanet Sand. The paper describes a section in the Bullhead Bed at Grays, where the conditions have been favourable for the chipping of the flints by subsoil pressure. There is evidence of extensive solution of the chalk beneath the Tertiary deposits, and the differential movements thus brought about have occasioned much slickensiding, and remarkable effects in the chipping of the flints. In the author's opinion the section affords the most complete and conclusive evidence hitherto obtained in support of the theory of the origin of the supposed eolithic implements by purely natural agencies. There are not only the simpler Kentish types, such as notches, bowscrapers, and the like, but also the larger and more advanced forms of rostrocarinates, which are characteristic of the sub-Crag detritus-bed. Careful digging enables the pressure-points of one stone against another and the resultant chipping effects to be studied in detail; and in many instances the flakes removed can be recovered and replaced. A few examples are more than merely eolithic in character. If such exceptional examples were removed from their associates, and also from the evidences of the geological forces to which they have been exposed, no investigator could be blamed for accepting them without question as of Mousterian workmanship. Individual specimens may often deceive: in order to distinguish a geological deposit of chipped flints from the débris of a prehistoric chipping-floor, it is necessary to base one's judgment upon fairly representative groups, and also to take into consideration the circumstances in which they have been discovered.

CAMBRIDGE.

Philosophical Society, March 8.—Mr. C. T. R. Wilson, president, in the chair.—H. H. **Brindley**: Further notes on the food-plants of the common earwig (*Forficula auricularia*). The observations on the food-plants of the common earwig made on a small scale in 1917 (Proceedings, xix., part 4, 1918, p. 171) were continued in the summers of 1918 and 1919 on earwigs kept in captivity in connection with a statistical inquiry on variation. Altogether about ninety species of common plants, chiefly garden varieties, were used. Among the most favourite foods were the *leaves* of Jerusalem artichoke, beetroot, pink begonia, garden cabbage, centaurea, delphinium, leek, *Malvus sylvestris*, vegetable marrow, mignonette, white pyrethrum, scarlet runner, seakale, and tomato; and the *petals* of blue Anchusa, China aster, pink begonia, blackberry, different varieties of campanula, white clematis, dandelion, Gesneria, white marguerite, mint, corn parsley, white phlox, yellow Œnothera, rose, tomato, red valerian, blue verbena, and varieties of vetches. Among *fruits* green fig, honeysuckle, and plum were well attacked, while apple was neglected until the skin was removed, and then eaten comparatively little. Potato and artichoke *tubers*, save dormant buds on the latter, escaped attack in their skins, but when sliced they were thoroughly devoured. The hairy undersides of the leaves of raspberry and blue verbena and the curled edges of Scotch kale leaves are very attractive to earwigs for hiding in in the day-time, and onion inflorescences, poppy capsules, buds of hollyhock, petals of garden chrysanthemums and snapdragon are also popular refuges. The last two and Scotch kale leaves were also nibbled moderately, but the conclusion formed in 1917 that the actual damage done to chrysanthemums by earwigs is usually exaggerated was confirmed by the later observations.—Miss Maud D. **Haviland**: Preliminary note on antennal variation in an Aphid (*Myzus ribis*, Linn.). The red currant Aphis (*Myzus ribis*, Linn.) shows variation of the antennæ in the winged females, according to whether they are fed upon healthy leaves or upon leaves blistered by the sucking of previous generations. In forms from the blisters the large sense-organs, situated upon antennal joints v. and vi., are placed nearer the articulation of these joints than in forms from healthy leaves. Experiments on transference of blister-fed descendants of a single ancestor to healthy leaves showed but slight change in the first two or three generations. Subsequent generations, however, showed marked increase above the ancestral mean, though identical generations, fed only upon blistered leaves, had a mean similar to that of their ancestors.—Dr. **Fenton** and A. J. **Berry**: Studies on cellulose acetate. The authors gave a short account of certain observations of general chemical interest obtained in the course of an investigation on aeroplane dopes.—G. T. **Bennett**: The rotation of a non-spinning gyrostat, and its effect in the aeroplane compass. "A symmetrical wheel free to rotate about its axle is moved from rest in any position by means of the axle, and is finally restored to a position in which the axle again points in the same direction as formerly. Show that the wheel, again at rest, will have rotated through a plane angle equal to the solid angle of the cone described by the varying directions of the axle" (College Examination Problem Paper, 1898). The kinematics of the angular motion of the wheel is

represented by the rolling of the plane of the wheel on a fixed cone of arbitrary form. The surface-angle of the cone differs from four right angles by the final angular displacement of the wheel. The same angle of rotation is also measured by the solid angle of the reciprocal cone described by the axis of the wheel. This movement is not yet among those that are familiarly recognised, though it has important practical applications. Bodies suspended from a point on an axis of symmetry behave in the same way and for the same reason when swung about by movements of the point of support. Aeroplane compass-cards in particular (found to keep practically parallel to the banked floor of the aeroplane under the action of gravity and lateral acceleration during a turn) would, from inertia alone, and apart from all other sources of control or disturbance, turn with the machine through an angle geometrically calculable from the movement of the aeroplane.—C. G. **Darwin**: Lagrangian methods for high-speed motion. The general form of the kinetic potential is found for any number of electrically charged particles moving in any field of electric and magnetic force, allowing for the variability of mass with velocity and for the "retardation" of the forces of interaction of the particles. The result is applied to the "problem of two bodies." The relative orbit is a distorted ellipse with moving apse, and there is no simply definable centre of mass for the system. The finiteness of mass of the hydrogen nucleus is found to have absolutely no effect on the separation of the doublets in the hydrogen spectrum.—H. P. **Waran**: The effect of a magnetic field on the intensity of spectral lines. The paper discusses the changes observed in the general spectrum and in the intensity of the lines when the source is placed in a magnetic field. In the case of mercury the field brings out a few lines previously faint or absent, and the abnormal behaviour of the line 6152, which is very prominently brought out, is discussed. In the spectrum of the monatomic gases helium and neon mixed with the diatomic gases oxygen and hydrogen, only the monatomic lines are enhanced very much in brightness, and on this view the fact of the lines getting enhanced in the magnetic field is attributed to atomic radiation. The differences in the degrees of enhancement are said to depend on the series to which the lines belong, and the enhanced lines in the sun-spot spectrum are attributed to this effect of the magnetic field known to exist there.—C. V. H. **Rao** and Prof. **Baker**: Generation of sets of four tetrahedra mutually inscribed and circumscribed. This paper shows how the figure is obtainable by a generalised process of inversion from a single tetrahedron, and applies the same method to a certain configuration in four dimensions.—S. **Pollard**: The term-by-term integration of an infinite series over an infinite range, and the inversion of the order of integration in repeated infinite integrals.—S. R. U. **Savoor**: Rotating liquid cylinders. This paper applies the method followed by Liapounoff, for the case of ellipsoids, to the consideration of the stability of the so-called pear-shaped cylinder.

DUBLIN.

Royal Dublin Society, April 27.—Dr. F. E. Hackett in the chair.—Prof. W. E. **Adeney** and H. G. **Becker**: The rate of solution of atmospheric nitrogen and oxygen by water (Part iii.). This paper deals with experiments made with bodies of quiescent water, the results of which show that under ordinary conditions mixing of the water takes place to such an extent that a modification of the formula previously deduced can be used to interpret the process. The effect of the humidity of the air above the surface of the water is also dealt with and its influence on the rate of solution indicated.—Dr. J. **Reilly** and W. J. **Hickinbottom**: (1) The influence of electrolytic dissociation on the distillation in steam of the volatile fatty acids. Changes in the distillation constants of the fatty acids are fully accounted for by introducing a correction for electrolytic dissociation. Observations are given on the influence of salts. (2) Some applications of the method of distillation in steam. A survey of the method, discussing its theoretical and industrial applications, especially in the analysis of butter and other edible fats and oils.

PARIS.

Academy of Sciences, April 26.—M. Henri Deslandres in the chair.—A. **Haller** and R. **Cornubert**: The constitution of the methylethyl*cyclo*hexanone prepared by the ethylation of α-methyl*cyclo*hexanone. This compound is shown to possess an unsymmetrical structure, both the alkyl groups being attached to the same carbon atom in the ring.—H. **Douvillé**: The origin of the Orbitoids.—A. **Blondel**: Theorems on the transmission of energy by alternating current analogous with those of Siemens on transmission by continuous current. Criticism of these theorems.—E. **Maillet**: Some properties of transcendental numbers.—C. **Camichel**: The permanent state in water reservoirs.—A. **Perot**: The variation with pressure of the wave-length of the lines of the cyanogen band.—F. **Bourion**: A method of physico-chemical analysis of commercial chlorobenzenes. By fractional distillation the specimen is divided into portions each containing only two constituents; measurements of density serve to determine the composition of each fraction. The accuracy obtained is illustrated by examples.—A. **Kling** and D. **Florentin**: The differentiation of masked and apparent sulphuric ions in complex salts. The use of benzidine as a reagent, suggested in a recent paper by P. Job and G. Urbain, was anticipated by the authors in 1914 in a study of solutions of the green chromium sulphate.—V. **Auger**: The salts of nitrosophenylhydroxylamine (cupferron): uranous salts. Uranic salts are not precipitated by cupferron, and vanadium can be quantitatively precipitated by cupferron in the presence of uranium, as was shown by Turner in 1916. If, however, by zinc reduction the uranic salts are converted into uranous compounds, the uranium can be precipitated also by cupferron, and under these conditions vanadium and uranium can be successively determined by means of the cupferron.—G. **Denigès**: Iodic acid as a microchemical reagent for calcium, strontium, and barium. A 10 per cent. solution of iodic acid forms a good reagent for the microchemical identification of calcium, strontium, and barium salts, soluble or insoluble. One milligram of material is sufficient for the purpose.—Ch. **Mauguin** and L. J. **Simon**: The action of chlorine, hypochlorous acid, and cyanogen on cyanamide and its derivatives.—P. **Bertrand**: Value of the primary centripetal metaxylem of old or primitive plants.—M. **Guilliermond**: The evolution of the chondriome during the formation of the pollen-grains of *Lilium candidum*.—H. **Devaux** and H. **Bouygues**: The usefulness of sodium fluoride employed as an antiseptic for the preservation of railway-sleepers. The scarcity of creosote has led railway companies to try other antiseptics for the preservation of wooden sleepers, and, among others, sodium fluoride has been extensively used. While there is no doubt as to the efficiency of sodium fluoride as an antiseptic, on account of the ease with which it is extracted by water, it is useless for the preservation of wood exposed to rain, and especially for the case of railway-sleepers.—A. **Desgrez**

and M. **Polonowski**: Determination of the total non-amino organic acids of the urine.—H. **Colin**: The diastatic hydrolysis of inulin. An account of some unsuccessful attempts to isolate products of hydrolysis intermediate between inulin and the reducing sugars.—J. E. **Abelous** and J. **Aloy**: Digestive hydrolyses by mechanical ionisation of water. Violent agitation is sufficient to determine a partial hydrolysis of solutions of starch, lactose, neutral fats, and fibrin. The effects increase with rise of temperature.—J. **Chaine**: Considerations on the paramastoid apophysis of man.—A. **Krempf**: Observations on the development of *Pocillopora cæspitosa* and *Seriatopora subulata*. Discovery of primitive stages revealing the scyphostrobiliary origin of the Anthozoa.—MM. **Weinberg** and **Nasta**: *Rôle* of the hæmolysins in microbial intoxication and the therapeutic properties of normal sera.—A. **Marie**, C. **Levaditi**, and G. **Banu**: Experimental transmission of the triponeme of general paralysis (*virus neurotrope*) by sexual contact.

The University of London: A Great Opportunity.

LAST week there was made public the details, printed elsewhere in this issue, of the offer by the Government of a site for the University of London. The Government proposes to give to the University about $11\frac{1}{2}$ acres behind the British Museum as a site for the University headquarters and for colleges and institutions connected with it, including King's College, the premises of which in the Strand have long been insufficient for the needs of the college. The Senate has referred the question to a committee the report of which will doubtless shortly be forthcoming.

None of Mr. Fisher's labours in the cause of university education—and they are many—will redound more to his credit than the attempt to provide the University of London with a home worthy of itself and of the capital city of the Empire. Since the reconstitution of the University as a teaching body in 1900, a great deal has been done in the organisation of university teaching and research in London. The professors and teachers of the University include many most distinguished men of science and scholars, and in the number of students it easily takes the lead in Great Britain. In recent years the University has drawn students from all parts of the world, attracted by the unique advantages which London can offer by reason of the resources of its libraries and museums. The establishment in the heart of the City of the School of Oriental Studies, and the association of business men with the foundation of the scheme of degrees of commerce, show also that the University can, by recognising the needs of the commercial interests of the City, obtain their active assistance and support.

It cannot be gainsaid, however, that, in spite of all that has been done, the University has as yet failed to justify the hopes of those who looked forward at its reconstitution to the creation of a great teaching university. We need not enter into a discussion of all the causes which have prevented or hindered the fulfilment of these hopes. Among them are the heterogeneous nature of the institutions—varying from colleges of the type of University and King's Colleges to polytechnic institutions—in which the teaching and research work are carried on, and the intricacy of its existing constitution.

But unquestionably the chief cause of the failure of the University to take the great place assigned to it has been the discrete nature of its component parts, the inaccessibility of its administrative headquarters, and the lack of a home or a quarter of its own to which one could point as *the* University. It is a commonplace that bricks and mortar do not make a university, but it is undoubtedly true that without a tangible symbol there can be no appeal to the sympathies or imagination of the public, and it is the absence of such a symbol which more than anything else has militated against an understanding of the work that the University has done and is doing. Until the University possesses a building indisputably its own and designed for its own purpose, and until the great incorporated colleges are brought together, there can be no hope of impressing the greatness of the University upon the public, or of overcoming the dissipation of energy which is now such a hindrance to its work.

The question is, of course, not a new one. Its importance has been appreciated for some time, and before the war there were negotiations in the air for the acquirement of a site in Bloomsbury. For various reasons these negotiations did not fructify, and it may be that the site then under consideration was inadequate and in other ways unsuitable. The objections offered to it are not, however, valid in the present case.

The site now offered is excellent in every respect. By reason of its proximity to Bedford College for Women and to University College, it is already the nucleus of the "University Quarter" desiderated by the Haldane Commission. It is sufficient in extent not only for the administrative headquarters, the University library, and King's College, but also for other colleges of the University which are outgrowing their accommodation; and it is capable of extension if still further accommodation is required.

It is, what South Kensington is not, an easily accessible place, and yet is not too noisy for the purpose, and it will have the additional advantage of the near presence of our greatest library and museum. It is safe to say that there is at present no site in London comparable with it, and none so suitable is likely to be available for many years.

The only objection possessing any validity to the acceptance of the Government's offer is the financial one. This is, we admit, a serious question, and it would be foolish to minimise its importance. Hitherto both the University headquarters and King's College have been housed free by the Government. This arrangement will now come to an end, and it is obvious that the cost of covering the site with buildings that shall be worthy of London's University will be considerable. Mr. Fisher feels that in this the University can look with confidence to the generosity and public spirit which have always marked the citizens of London. We think he is right. We are convinced that, if proper efforts are made, enough and more than enough money will be forthcoming for the purpose. The results of the present Vice-Chancellor's appeal to the City in connection with the degrees of commerce of the University afford an index of the support that would be forthcoming from the City Companies and the great commercial houses if the sympathies and the co-operation of the commercial community were enlisted in the greater cause of the University as a whole. Private benefactors would be attracted to a bold and well-conceived plan of creating a great university quarter, and Londoners, if there were some outward and visible sign of the greatness of their University, would not be found wanting either in the civic pride or in the willingness to pay which is found in the provinces or in Continental cities.

We hope the University authorities will take their courage in both hands and go forward boldly. The reasons which forbid the Government from giving further assistance in these days may be regrettable, but they are easily intelligible. We are sure that if the University rises to the occasion neither this nor any future Government will be allowed to leave it to struggle unaided. We are equally sure that if counsels of timidity are allowed to prevail and this opportunity is lost the University will have forfeited irrevocably any claim on the public or the Government for support in the future.

Manuals on Applied Chemistry.

(1) *Practical Leather Chemistry: A Handbook of Laboratory Notes and Methods for the Use of Students and Works Chemists.* By Arthur Harvey. Pp. viii+[illegible]. (London: Crosby Lockwood and Son, 1920.) Price 15*s.* net.

(2) *Chemistry for Textile Students: A Manual Suitable for Technical Students in the Textile and Dyeing Industries.* By Barker North, assisted by Norman Bland. (Cambridge Technical Series.) Pp. viii+379. (Cambridge: At the University Press, 1920.) Price 30*s.* net.

(3) *The Chemistry of Coal.* By John Braithwaite Robertson. (Chemical Monographs.) Pp. viii+96. (London: Gurney and Jackson, 1919.) Price 3*s.* 6*d.* net.

(1) MR. HARVEY'S handbook is intended for the use of the works chemist in charge of the analytical and testing department of a tannery. It is an eminently practical work, well and clearly written with due regard to modern methods, and evidently based upon considerable personal experience. It presupposes that the user of the book has had not only a preliminary course of instruction in theoretical chemistry, but also the opportunity of a laboratory training in manipulation in qualitative and quantitative analysis. In these circumstances the book can be thoroughly recommended as an excellent *vade mecum* to the work of the chemical laboratory of a tannery, or to the student who intends ultimately to specialise on leather chemistry. It will be found to cover practically every problem that the works chemist of a tannery may have to face. The analytical methods described have been thoroughly tested, and are well adapted to practical conditions.

(2) The manual by Mr. Barker North and Mr. Norman Bland is a work of a very different class. It is essentially a text-book of the elementary chemistry of certain of the non-metallic elements and their compounds, together with a somewhat bald account of the chemistry of a few carbon derivatives. The section devoted to technical chemistry as applied to the textile industries occupies only some twenty-eight of the 379 pages of which the book consists. The authors are lecturers in chemistry to the evening classes of the Technical Colleges of Bradford and Huddersfield respectively, both important centres of the textile and dyeing industries, and their object, no doubt, is to attract students who are, or may be, engaged in these industries. In their preface they point out that whilst the cotton and woollen industries occupy most important positions

among the nine leading industries of the country, it is only within recent years that even enlightened employers have begun to realise that chemistry and physics play a most important part in the various operations used in the production of yarns and finished pieces."

All this may be very true. But it is equally true that the hard-headed Yorkshire manufacturer who turns over the pages of this well-printed and handsomely illustrated book will be slow to perceive wherein it bears directly upon his industry. He will be apt to think that the kinetic theory and Avogadro's hypothesis have as little to do with woollens and worsteds as the binomial theorem has with the common pump. There is not the slightest intention to minimise the importance of a knowledge of the principles upon which chemistry as a science is based, or to depreciate its value when applied to industry. It is admitted, of course, that no technologist is adequately trained who is wholly ignorant of the science. But in compiling a text-book which would seem to be mainly directed to the work of their classes the authors have attempted too much. They have mixed up purely elementary doctrinal chemistry with applications involving a very different kind of knowledge. The problems of textile chemistry are far more recondite than their association with rudimentary chemistry, as in this book, would seem to imply. We have no fault to find with the book as a text-book to accompany an experimental course of evening lectures such as the authors are engaged in giving, except that its price will probably be beyond the means of the ordinary evening-class student.

The course as set out in the book is well arranged, and it is intended that the pupils shall themselves perform many of the elementary experiments described, presumably in a laboratory class. There is no doubt that if they work through the list under competent direction they will acquire a considerable amount of information, and gain some proficiency in chemical manipulation. No special experiments are described in the section devoted to the systematic study of the non-metals and their important compounds, or in that concerned with the chemistry of the hydro-carbons and their derivatives, but the student is directed to "pick out the portions which are suitable for experimental illustration with the apparatus at his command"—a direction which, it may be hoped, will strengthen any latent power of original investigation that he may possess.

The scope of the teaching has presumably been limited to what has been found to be practicable in such courses of evening-class instruction as are possible in the institutions with which the authors are connected, and there can be no doubt that if the beginner faithfully follows the teaching and supplements it by reading the "larger and more specialised works" to which he is referred, and which, it is to be hoped, he will find in the libraries of the schools to which he may be attached, he will have acquired a very fair acquaintance with the elements of chemistry. But as he pursues his reading, and enters upon the perusal of the more specialised works on the chemistry of textiles, he will realise that he has got no further than the alphabet of the subject. After all, a knowledge of the alphabet is an essential step, and it may be that the authors, *pace* the title of their book, have aimed no higher. The time will come when our technical schools will not mix up elementary with applied teaching, but make each section independent. Applied chemistry must of course be based on elementary and theoretical chemistry, but there are no short cuts to proficiency in any one branch, and it is a bad system of instruction which fosters the idea that there can be.

(3) In about ninety small octavo pages Mr. J. B. Robertson, lecturer in chemistry at the South African School of Mines and Technology, Johannesburg, has sought to give an account of the chemistry of coal. His title may be held to imply more than his little monograph actually covers, as he confines himself to a very limited portion of what in reality is a very wide field, and has very little to say respecting the chemical derivatives of coal, except to the extent that they may be supposed to throw light on the nature of the proximate constituents of coal. In five short chapters, or sections, Mr. Robertson discusses the mode of occurrence of coal, its origin, and the various methods of classifying it; the action of solvents, *e.g.* benzene and pyridine, etc., upon the coal substance; its oxidation and destructive distillation. The summaries are exceedingly short, but they are accurate and fairly up-to-date, and at least serve to show how much remains to be done before the real chemical nature of coal is elucidated. Practically all that we know at present is that coal consists of a variable and indefinite mixture of at least two constituents, one of which appears to be a degradation product of cellulose, and the other a resinoid substance which can be extracted by appropriate solvents; and that it is upon the relative proportion of these constituents that the technical value and industrial applications of coal largely depend. But the precise nature of these constituents is as yet very imperfectly defined, and the suggestions that have been made as to their origin are little more than surmises.

The most detailed sections of the book relate

to the analysis of coal, proximate and ultimate; these, compared with the preceding sections, are remarkably full and evidently based upon personal experience. It would have added to the comprehensiveness of the account if a description of the methods of determining arsenic had been given. Owing to legislation arising out of the arsenic-in-beer scare the value of coal, especially anthracite, for kilning purposes is greatly affected by the presence of even small quantities of arsenic. The method of determining the calorific value of coal would have been rendered more intelligible if the description had been accompanied by an illustration of the calorimeter. Lastly, we deprecate the practice of placing the bibliographical references in the text at the end of the book. This method, at least as regards chemical literature, seems to have originated in Germany. We fail to perceive that it has a single redeeming feature. On the contrary, it produces the maximum amount of inconvenience. It involves constant turning backwards and forwards, which is apt to become tiresome and to lead to error. It is far preferable to embody the references in the text, or at least to place them as foot-notes to the pages on which they occur.

A Standard Book on Soils.

The Soil: An Introduction to the Scientific Study of the Growth of Crops. By Sir A. D. Hall. Third edition, revised and enlarged. Pp. xv + 352. (London: John Murray, 1920.) Price 7s. 6d. net.

IT is pleasant to see that Sir Daniel Hall's book on the soil has now reached a third edition. It will have a permanent place in British agricultural literature as the first book on the subject in the modern period. Its distinguishing feature, which marked it off from its predecessors, is its clear recognition of the complexity of the soil problem, emphasised in the opening words and maintained throughout: "In the scientific study of soils, chemical, physical, and biological considerations are involved." Successive generations of earlier workers had regarded soil fertility as essentially chemical, physical, or bacteriological. This book was the first to show British readers that all these different views had a basis of truth, but that each by itself was too narrow. The study of the soil, in short, cuts across the conventional divisions of science and brings together such apparently diverse workers as the physicist and the protozoologist, the mathematician and the plant physiologist, and others who in an ordinary scientific laboratory would be supposed to have nothing in common.

To write an adequate review of the book, comparing it with the preceding editions, would be to write a history of the development of modern soil science, and could not be done in a short notice. The leading advances have been in our knowledge of the constitution of the soil and of the population inhabiting it. In both directions recent investigations have revealed greater complexity and emphasised still further the need for "team" work to supplement the indispensable, but limited, individual work.

Ten years ago there was only one soil biologist at Rothamsted; now there are nine, and others, it is hoped, will soon be added. Bacteria were at first supposed to be the only organisms concerned; now it is realised that fungi, actinomycetes, algæ, and protozoa are all present in the soil, and probably all concerned in some way in the great changes going on.

Sir Daniel stimulates a living interest in the subject and makes constant reference to the experience of farmers, gardeners, and others in soil management and in the behaviour of plants in different soil conditions. These serve to show the student how much remains to be done in spite of all the advances of recent years; in this way also the book acts as a valuable corrective to the tendency showing itself in certain modern textbooks of regarding the soil as a physico-chemical system the properties of which are expressible in mathematical terms. These analytical methods have their uses, but they would become dangerous if they were allowed to obscure the complexity of the problem.

There is a valuable section on soil types containing much information of interest to the ecologist as well as to the agriculturist. The section on land reclamation is of particular interest at the present time and has a breadth of view and a freedom from extravagant anticipations rarely found in discussing this important subject. Altogether the book keeps up its reputation and will prove invaluable to the serious student of the subject.

E. J. R.

Savages of the Far Past.

An Introduction to Anthropology: A General Survey of the Early History of the Human Race. By the Rev. E. O. James. Pp. ix + 259. (London: Macmillan and Co., Ltd., 1919.) Price 7s. 6d. net.

MR. JAMES aims at introducing the student not so much to anthropology in general as to prehistoric archæology interpreted in the light of the study of primitive man, modern as well as ancient. After an introductory chapter outlining

the scope of anthropology conceived as the study of man in evolution, he proceeds to sketch the evidence relating to the side of somatology. Considering the limitations of space, his account seems fairly complete. A few slips occur. *Trogontherium* will scarcely do as the name of a kind of elephant. *Rhinoceri* reminds us of *octopi*. More important, it is a pity to adopt Klaatsch's term "Aurignacian man" to describe a physical type (Combe Capelle), seeing that to do so is to correlate a race with a cultural type which may or may not have been confined to that race—nay, probably was not. Next, the characteristic forms of industry are described. We note that Mr. James is inclined to accept the Sub-Crag flints as of genuine human workmanship. He also takes the view that the Mousterian industry is inferior to the Acheulean, representing a set-back in culture and not an advance as effected by a labour-saving device. Mr. James is entitled to judge at first hand, inasmuch as he has worked on a Mousterian site (Jersey), where material was plentiful. Perhaps he does not sufficiently allow for the fact that, if finely wrought pieces were but as one in every hundred fragments forming the workshop refuse, these masterpieces were of a very high quality, symmetrical in outline and smoothly and delicately finished off.

The book then goes on to try to construct some picture of the social organisation and magico-religious beliefs prevailing during the prehistoric period, and especially among the later cave-men. Necessarily the treatment is somewhat speculative, but the analogies provided by modern savages are put forward without dogmatism and so as to invite the student of archæology to equip himself for his special task by acquiring the elements of anthropology as a whole. Mr. James has already written on the subject of primitive religion, with special reference to the Australian aborigines. The latter, then, naturally provide him with most of his clues, but here he has the support of most writers on this branch of the subject, from M. Salomon Reinach onwards. Certainly it is hard to resist the impression that the drawings found in the deep recesses of caverns, as at Niaux, served a magico-religious purpose; art for art's sake would surely have craved a good light. What, then, more natural than to compare the Australian *intichiuma* ceremony with its rock-drawings demonstrably designed to further the multiplication of animals and plants fit for human consumption? It does not follow, of course, that every institution of the Australians can therefore be fathered on the men of Pleistocene Europe. Totemism is more doubtful than *intichiuma*; delineations of embryonic spirits (*inapertwa*) are more doubtful than either; while *churingas* and Azilian coloured pebbles are not to be identified offhand. Mr. James, however, steers his way warily among these tempting possibilities, and the result is a manual which will make the student think without professing to supply the thought ready-made. R. R. M.

The Problem of Clean and Safe Milk.

The Modern Milk Problem in Sanitation, Economics, and Agriculture. By J. Scott MacNutt. Pp. xi+258+16 plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1917.) Price 10*s.* 6*d.* net.

THE purpose of the author of this volume is to provide a convenient survey of the practical, economic, and sanitary factors of the milk problem, so as to meet the needs not only of health officers and milk inspectors, but also of dairymen, city milk dealers, agricultural authorities, consumers, physicians, and all others who are interested in the problem.

This survey is almost entirely based upon the experience gained in the United States as set forth in official reports or publications which have appeared in America, mostly since 1910.

The author knows that the milk question has also received the attention of some European workers, and refers in a few words (p. 66) to the communication made by Mr. Ernest Hart at the International Medical Congress held in 1881, in which mention is made of sixty-nine epidemics of disease attributable to milk. The only other English writer specifically mentioned in the text is Smollett (p. 32); the very realistic description of the milk consumed in London introduced by that author in a letter of Mr. Bramble to Dr. Lewis ("The Expedition of Humphrey Clinker") is certainly very interesting, for it shows that the milk problem already exercised the minds of thinking men some 150 years ago.

Although European observers have little to learn from their American colleagues regarding the causes of the deplorable state of the milk consumed in large and other towns, and its serious consequences, it must be acknowledged that greater enterprise has been shown in the United States in the devising of methods and regulations having for their object the improvement of the milk supplies.

It is specially on that account that the book will prove useful to British readers, who will find in it a comprehensive and critical summary of many of the results obtained in America by sanitary and agricultural authorities, as well as by various

committees, associations, and individual observers. The author shows not only that much progress has been made towards the solution of the problem, but also that some of the methods which have been tried, such as the score-card method of inspection, are by no means so useful as some enthusiasts on this side of the Atlantic have proclaimed.

The author is justly impressed by the merits of the North system (p. 78), the object of which is to prevent contamination of the milk at the time of milking by simple but essential precautions which can be taught to any farmer, the part of the work which cannot safely and economically be carried out at an ordinary farm being undertaken at well-equipped stations.

The quality of the milk is determined by the amount of butter-fat and the number of bacteria. A premium is paid for milk containing less than 10,000 bacteria per c.c., and also when the butter-fat exceeds a certain standard—say, 3·7 per cent.

Notwithstanding many repetitions, the book is interesting from beginning to end, and is written in a clear and popular style, which to an English reader derives a certain quaintness from its Americanisms.

SHERIDAN DELÉPINE.

Our Bookshelf.

The Whole Truth about Alcohol. By George Elliot Flint. With an introduction by Dr. Abraham Jacobi. Pp. xii+294. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 6*s.* net.

THE writer of this book is an uncompromising anti-prohibitionist, and a whole-hearted supporter of St. Paul's dictum with regard to the use of alcohol. He considers that alcohol has been greatly maligned, that many of the vicious attacks upon its use have no basis of real evidence, of reason, or of common sense, and that its influence for evil and as a deteriorator of the human race has been, at least, greatly exaggerated. He discusses *seriatim* the many statements that have been advanced regarding the deleterious action of alcohol, even in the most moderate doses, and the better state of total abstinence, and he adduces many arguments and some facts contravening these.

On the whole, the tenor of the book is reasonable, and the conclusion is that moderation never hurt anyone, and in some respects is better than total abstinence. With many of the author's views we are in sympathy, and we fully agree that prohibition is not the best route to temperance. Like him, we doubt if the moderate use of alcohol is in any sense deleterious; but the difficulty is to define what is moderation, and we are sure that many who take alcohol in what they regard as strict moderation are exceeding the harmless dose. For anyone who desires the anti-prohibition view the book will furnish a wealth of matter, but it is written largely from the American point of view.

Dr. Jacobi contributes a brief but interesting introduction, in which he states that in the worst cases of sepsis and toxæmia—*e.g.* in diphtheria and puerperal fever—alcohol in the largest doses furnishes the only salvation. With this view we largely agree; but the use of alcohol in disease is of course on a very different footing from the general use of alcoholic beverages in health.

R. T. H.

The Geography of Plants. By Dr. M. E. Hardy. Pp. xii+327. (Oxford: At the Clarendon Press, 1920.) Price 7*s.* 6*d.* net.

THE present volume is a continuation of the introduction to plant geography by the same author issued in 1913 as one of the series of the Oxford geographies designed by the late Prof. and Mrs. Herbertson. It may be regarded as an expansion of part iii. of the earlier work; the slight survey of the continents given there has served as the plan for the new book, which embodies a discussion of the conditions in which plants flourish, and their distribution in the great geographical divisions of the earth. The great continents are considered in successive chapters—Asia, North America, South America, Australia, Africa, and Europe—and each chapter gives a concise account of the physical features and climate, the bearing of these upon the extent and character of the vegetation, and their relation to the support and development of mankind. The book is profusely illustrated with maps and a well-selected number of photographic reproductions of aspects of vegetation. There is a geographical index, and also one of plant names, in which the scientific and popular names of the plants referred to are arranged under the different continents. The little volume should interest alike students of geography and botany, and botanists especially will welcome it as filling a gap in their series of text-books.

A Handbook to the Vertebrate Fauna of North Wales. By H. E. Forrest. Pp. v+106. (London: Witherby and Co., 1919) Price 6*s.* net.

MR. FORREST, the author of "The Vertebrate Fauna of North Wales" (1907), has now published this shorter "handbook," convenient for naturalists and interested visitors. It deals with 28 prehistoric mammals, 8 mammals extinct during the historic period, 43 existing mammals, 227 birds, 5 reptiles, 6 amphibians, and 151 fishes. Under each species is a brief summary showing its status and distribution in the area. Trustworthy information has been collected from many observers, and the whole work is marked by careful precision, an indispensable quality in faunistic census-taking.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Scientific Work: its Spirit and Reward.

THE true incentive of the scientific worker is his work. Through his work he expresses the creative thought within him, which he feels to be his highest life. This expression must through its very nature be free, otherwise he becomes a slave in the worst sense, in that the free exercise of intelligence is denied him.

Because this freedom is sacred to the scientific worker he sometimes has to sacrifice income and the possibility of family life to retain it, but this is a mere misfortune, not in any sense a necessary concomitant of scientific ability. The sentimentalist and the exploiter have promulgated the idea that the scientific worker, being exalted above the need for normal human joys and amenities, works best on the smallest possible income; or, having found that this does not always work out in practice because it tends to reduce the output of useful results, as the reduction of rations to one bean per day led to the unfortunate demise of the horse, the opposite line is taken, and it is supposed that by large remuneration the valuable work looked for can be bought.

Neither the one nor the other point of view is correct. The scientific worker if he is normal needs the means to enable him to have a happy, care-free home-life, and to educate his children in such a way that they in turn may be free as he would be. Therefore to starve him is to eliminate the normal and consequently intelligent worker in favour of the eccentric. For let it be clearly stated, the highest intelligence is always supremely sane. The idea of a scientific worker as a harmless lunatic is by no means confined to sensational fiction, although it might as well be imagined that every long-haired user of a piano is a Paderewski, or every loose-tied splasher of paint on canvas a Sargent.

On the other hand, to believe that creative thought can be purchased with money is to repeat the mistake of Simon Magus. Imitative thought in all its manifestations can be obtained for an adequate remuneration, because it can be produced by outward drill, discipline, and experience. So experts in the orderly routine dear to the official mind can be turned out by mass-production like cheap crockery, and are similarly useful and indispensable.

There is, however, no means of estimating the value of one really original thought either in pure or in so-called applied science. Certainly the possession of anything like its value in money would often be an embarrassment to the scientific worker through whom it is expressed. He also would be the first to disclaim any absolute or exclusive right to it. In the last analysis, humanly speaking, there is no such thing as an absolutely original idea, and it is seldom that any single individual can claim undivided credit for bringing a new idea to birth.

On the other hand, to divide its money-value, if it have any, in such a way that little or nothing comes back to the immediate originator is simply unjust, and therefore ultimately disastrous.

A certain type of person sniffs at Lord Kelvin for having become part owner of numerous important patents. No one will deny Lord Kelvin's position as a scientific worker; that he was also a business man merely means that his gifts were more readily applied to the good of humanity.

That a scientific worker should be debarred from any reward or protection by patents embodying his discoveries, because of his occupying either a public or private salaried position, is not only unjust, but also often unbusinesslike and against the public interest. The equitable adjustment of rights and returns as between public or private capital and the actual inventor is often the only way to prevent exploitation by purely selfish private interests.

To repeat, the true incentive of the scientific worker is his work. Salary, kudos, position, *esprit de corps*—these are incentives to good and useful people, but they are not the true incentives of the real scientific worker. To obtain the best from him, he must before all things have freedom, and, if possible, also a reasonable measure of justice.

"The bearings of this observation," as Capt. Bunsby in "Dombey and Son" remarked, "lays in the application on it."

GILBERT J. FOWLER.
Indian Institute of Science, Bangalore, India.

Applied Science and Industrial Research.

AT a meeting held at the Birkbeck College on April 28, organised by the National Union of Scientific Workers to urge more public support of scientific research, Prof. Soddy, the principal speaker after Mr. H. G. Wells, who occupied the chair, made a strong attack on the Department of Scientific and Industrial Research and the industrial research associations which have been, and are being, established under its ægis (see NATURE for May 6, p. 309). As much of Prof. Soddy's criticism seems to lend colour to current misconceptions of industrial research and of the functions of the research associations fathered by the Department of Scientific and Industrial Research, I beg the hospitality of your space for the following observations.

No one disputes the vital and urgent need for increasing the facilities for scientific study and scientific research. All those who know the facts will echo Mr. H. G. Wells's just indignation at the national neglect of science and the half contemptuous treatment by the State of our great men of science. I go further and agree with Prof. Soddy that in the extension and intensification of scientific study and research the claims of pure science must be primary and paramount. But I deny emphatically that this involves a similarly short-sighted and contemptuous attitude towards the needs of applied science and industrial research. If English industry has suffered too long from the dominance of mere rule-of-thumb methods; if our manufacturers have, through ignorance, underrated the value of science, the fault has not been wholly and exclusively theirs. The academic people who have contemned applied science and industrial technology as something little better than a crude empiricism must bear some share of the blame. The manufacturer may have kept his feet too much in the mud; the academician has too often kept his head entirely in the clouds. If one has been too disdainful of scientific methods that did not ensure or promise immediate dividends in cash, the other has talked at times as though the mere prospect of a utilitarian issue to a specific research were enough to defile it and make it unworthy of his serious attention. We all know the type of academic science worker to whom an investigation of the internal structure of the atom is a noble and purifying pursuit, and

a research on soap an ignoble and degrading occupation; as though atoms *per se* were inherently dignified and only became disreputable when associated with other atoms to form the molecules of a useful, if homely, commodity. There are many forms of snobbery. Pure science itself has had to put up with a good deal of classical snobbery, as Mr. Wells has more than once testified. I doubt whether matters will be mended by a development of such a form of scientific snobbery as seems often to be the inspiration of the disparagement, in academic circles, of applied science and industrial research.

Fortunately this attempt to erect an arbitrary and artificial barrier between pure and applied science is becoming progressively discredited as the nature of industrial research and its dependence on pure science are becoming better known. Every research in applied science, if it is to be thorough, involves some research in pure science. An industrial problem may be, and often is, the starting-point of a research that may widen the bounds of knowledge as much as any research born of a conception in pure science. Applied science and industrial research have been developed more widely in America than in any other country, if we except Germany. How does American experience confirm the view that to foster industrial research is to starve pure research? In the paper on "Industrial Research in the United States of America" by Mr. A. P. M. Fleming, published for the Department of Scientific and Industrial Research, there is abundant testimony to the recognition, by firms and institutions engaged in industrial research, of the importance of pure science research. Such an industrial leader as Dr. J. J. Carty, vice-president of the American Telephone and Telegraph Co., in his presidential address to the Institute of Electrical Engineers in 1916, emphasised this view: "By every means in our power, therefore, let us show our appreciation of pure science, and let us forward the work of the pure scientists, for they are the advance guard of civilisation. They point the way which we must follow." Mr. Elihu Root, chairman of the board of trustees of the Carnegie Institution of Washington, in a paper on the need for organisation in scientific research, makes the same point: "While the solution of specific industrial problems and the attainment of specific industrial objects will be of immense value, the whole system will dry up and fail unless research in pure science be *included within its scope*." Mr. W. A. Harmor, assistant director of the Mellon Institute of Industrial Research, University of Pittsburgh, bears similar testimony to the needs of pure science: "The wide view is now taken that, in considering the needs of industry, pure science investigation has as essential a contributory function as that specifically devoted to the attainment of some technologic objective." One could multiply almost indefinitely such tributes to the primary and paramount necessity of investigations in pure science from men and organisations concerned mainly with industrial research. Prof. Soddy's argument that for the million of money which the Government has expended or earmarked for scientific research pure science has got little or nothing is, therefore, based on a misconception of the nature of industrial research, and is directly contradicted by past experience and present knowledge.

The assumed antagonism between pure and applied science is baseless in fact and mischievous in tendency. As Mr. Harmor has well said: "Both pure and applied research are of the same order of importance and each has its own related field." The alleged inferior character of applied research as compared with pure research has no better foundation in fact than the alleged inferiority of scientific studies, as instruments of intellectual training, to classical studies. As Mr. A. W. Mellon, president of the Mellon National Bank of Pittsburgh, in an article on the value of industrial research, aptly expressed the matter: "The fundamental differences between pure research and industrial research are, indeed, traceable to the differences in the poise and personality of the representatives of each type of scientific investigation. Success in genuine industrial research presupposes all the qualities which are applicable to success in pure science, and, in addition, other qualities, executive and personal, more or less unessential in the pure research laboratory."

It would be strange if it were not in line with other experience that every time an attempt is made to extend and foster applied science and industrial research someone raises the cry that pure science is thereby being neglected and starved. This is to argue as though the total fund, both of money and energy, available for the purposes of scientific education and research were a fixed fund, so limited that any amount devoted mainly to the purposes of applied science must thereby lessen the sum available for pure science. It is a fallacy on a par with the trade-union notion that increased production by the individual worker will increase unemployment, and, by augmenting the profits of the employers, diminish the wages of the employees; and it is a proof, if proof were needed, that academic trade unionism can be as selfish and short-sighted as any other kind. Yet, just as the present condition of Europe affords a plain proof of the economic truth that the weakness of one nation impairs the strength of all, so will the cause of pure science not be bettered, but rather worsened, by attempts to crab the progress of industrial research.

The Department of Scientific and Industrial Research, as Sir Frank Heath has well said, is engaged on a great adventure. Thanks largely to its efforts, already the spirit of science is stirring among the dry bones of industries to which it was previously little known. The research associations formed and to be formed, which will cover a wide and diversified area of British industry, are attracting, and are destined to attract, scientific workers of the highest distinction and widest outlook, among them, no doubt, many of the members of the National Union of Scientific Workers, under whose auspices Prof. Soddy made his attack on the Department and the research associations. I submit that the cause of pure science is not well served by inconsiderate attacks on this industrial research movement, which is admittedly a novel experiment, beset by unforeseen, because unprecedented, difficulties, but the success of which must react to benefit pure science as well as to redeem British industry.

J. W. WILLIAMSON.

26 Russell Square, W.C.1, May 6.

A Rainbow Inside Out.

IN February last Mr. P. H. Hepburn directed my attention to some surprising light-bows he had observed on several occasions on the surface of one of the ponds on Hampstead Heath. On February 24 we examined them together. A footpath lighted by three electric street-lamps runs along the southern edge of the pond. As one passed along this path bright bows of strange forms cast by the lamps were seen to spring out from the edge. The night was dark, the air still and slightly foggy, and the water smooth and covered with a film of scum extending as far as we could see in the dim light. There was no frost. The bows were judged to be on the surface

of the water, which was only about a foot below the level of our feet.

The form of the bows is shown in Fig. 1, which is taken from a rough sketch made by the writer from memory after returning home and before any explanation of the phenomenon had suggested itself. Here O is the observer in three positions, I., II., and III., and the bows seen from these positions are numbered correspondingly. The twin bows seen in position I. and the double curvatures at *a* in positions II. and III. struck us as remarkable. As the observer moved from the first position to the second, the nearer branch of I. sank into the bank of the pond and the

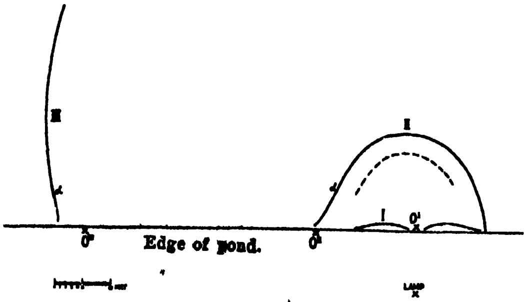

FIG. 1.—O^{I}, O^{II}, O^{III}, three positions of the observer's eye; I., II., III., the bows seen in these positions; *a*, points of double curvature.

further branch sprang out in a somewhat startling manner until it attained the size roughly shown at II. The observer proceeding towards III., the apex of the bow, became lost in the distance.

The bows were colourless except for a tinge of red on the inside and of light of shorter wave-length on the outside. They formed the limiting inner edge of faint, diffuse luminosity extending over the general surface of the pond, and within the bows was darkness. In position II. a ghost of an inner bow was seen within the principal bow, roughly as shown in the figure. No colour could be distinguished in this inner bow.

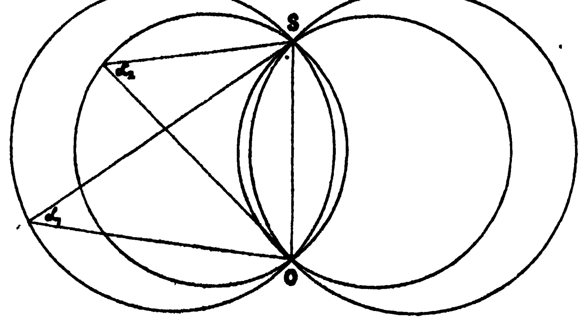

FIG. 2.—S, source of light; O, eye of observer; a_1, a_2, angles of minimum deviation for primary and secondary bows respectively.

In the first position the surface of the water was only about 5 ft. below the eye, and around the shadow of the observer's head—on the fog as we thought at the time, but on the water-surface as we now believe—the diffuse light was brighter, forming an aureole a few inches in breadth. When the head was turned slightly, so that a ray of light from the lamp to the water could pass close to the eye, the aureole at the edge of the shadow near this eye became brighter, suggesting that a ray reflected directly back on itself was of considerable intensity.

On subsequent nights we returned to the spot in the hope of again seeing the phenomenon, but, doubtless owing to a change in the weather conditions, we saw nothing. We took measurements, however, and from these data Figs. 3 and 4 were calculated.

The explanation of the phenomenon appears to be as follows:—In certain weather conditions globules of water are deposited from the fog upon the scum on the surface of the water, and the bows are formed in a way similar to those cast by the sun upon a bedewed field—with this difference: that here the source of light is near the observer. The bows, indeed, are rainbows.

In order that a drop of water shall be so placed as

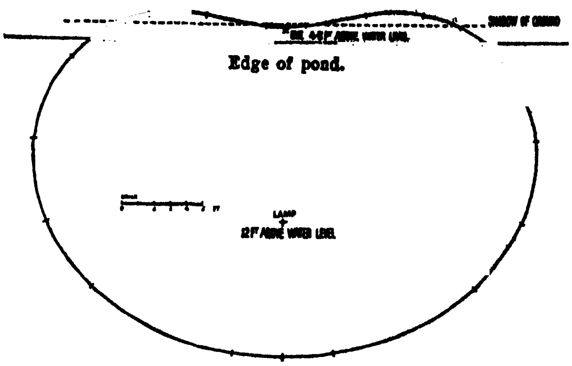

FIG. 3.—Primary bow, position I., as calculated.

to return to the eye a maximum amount of light in the manner that obtains in the rainbow, it is necessary that the line joining the source to the eye shall subtend an angle *a* at the drop, where *a* is the angle of minimum deviation. The locus of such suitable positions for the drop is the surface of revolution of a circle, of which the line joining the source to the eye is a chord, about this chord (see Fig. 2). The locus, then, is a toroidal figure like a flattened apple. The locus for the secondary bow is such a toroidal

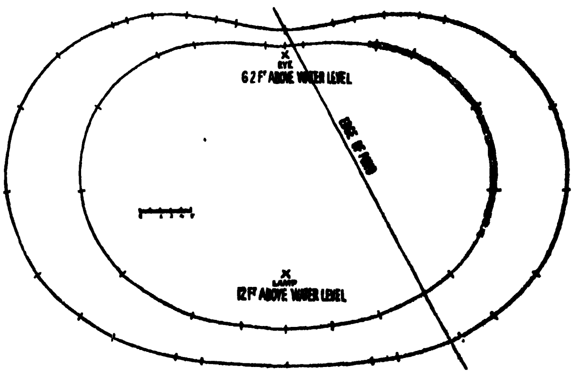

FIG. 4.—Primary and secondary bows, position II., as calculated.

figure within that for the primary bow. When the source of light is at infinity, as in the case of the sun, these figures become resolved into two co-axial conical surfaces having the eye at their common apex. In the present case the drops were confined to the plane surface of the water, and the bows seen were plane sections of these figures.

In order to test the soundness of this explanation, the writer has calculated the form of the bows from the equation of the section of the toroidal figure made by the water-surface, using as data the measurements taken of the positions I., II., and III., and giving *a* the values 42° and 53° for the primary and secondary

bows respectively. The results for I. and II. are shown in Figs. 3 and 4. It is unquestionable that these curves faithfully represent the phenomenon as we observed it, the portions shown with thicker lines being those within the limits of the water, which alone we were able to see. The calculated curve for III. (not shown) is equally corroborative. The aureole seen round the shadow of the observer's head is consistent with the attribution of the phenomenon to water globules upon a surface (see J. M. Pernter, "Meteorologische Optik," 1910, p. 424).

It is of interest to note that the closed curve is a rainbow inside out, and with the secondary bow within the primary.

Since writing the above we once again found the bows visible, and a careful examination of them seemed to confirm the conclusions arrived at on every point. On this occasion the film was broken by spaces of clear water, and at these spaces the bows were interrupted. The space within the inner bow was filled with faint, diffuse luminosity, and a marked feature was the blackness of the zone between the inner and outer bows. C. O. BARTRUM.

"All-or-None" in the Auditory Nerve.

PROF. D. C. MILLER ("The Science of Musical Sounds," 1916, p. 184) admits the reality of beat-tones, but says that they are purely subjective, having no physical existence. This seems unsatisfactory. To begin with *beats*, it is wrong to say that it is the places of maximum intensity which are properly called *beats*. This is an illusion, due to too familiar diagrams. The maximum of intensity occurs at no place, but at a point of time which, at its own instant, the maximum not being absolute, is not impressive. At any point of time the next vibration of a sound may be of greater amplitude or it may not, and the listening ear, being unable to foretell, cannot tell us in the present when the maximum is attained. The perception of a maximum is bound to arrive, in fact, the day after the fair, when the sound is on the wane. On the contrary, it is the minimum of intensity which gives the effect of the beat. This is clear if the two primary tones are of equal amplitude and there is a phase of silence, when the difference of sensation is a difference, not of *degree*, but of *kind*. It has been shown that if a musical note is suddenly reduced to silence, the interruption of the series of vibrations restores the last of the series of periodic impulses to its isolated value; the note ends with a kind of shock or tap, comparable to one of a series of hard beats. If periodic beats are rapid enough, the final impulses at the interruptions form a fresh series, and are free to evoke in the sensorium a sensation of tone of the same frequency as the beats, a beat-tone; and this is best observed when the beats are not too violent.

Beat-tones are, therefore, no more subjective and have no less physical existence—although they may have been invisible hitherto in tracings and photographs—than any other real tone; and since both beat-tones, $p-q$ and $2q-p$, are best heard, at least with intervals less than an octave, when the primaries are not powerful, there never has been a good reason for rejecting Young's view of their origin, nor for ascribing to Koenig the discovery of those "upper" beat-tones which were discussed by Young before the Royal Society in 1800. (In Faraday's copy of the 1807 quarto there is a book-mark at p. 544 of vol. ii., perhaps indicating that the chapter on the coalescence of musical sounds has more than an historical interest.)

But beats are produced by primaries of unequal amplitude, and in such cases there is no phase of silence, and apparently no absolute minimum of intensity. Here we have something comparable to the first *d* in "would do" rather than the first *t* in "not too," to a *voiced* rather than a *voiceless* occlusive. If in the physiology of hearing we assume similarity of character in the nervous impulse to that which is established for motor nerves, the contribution of a single nerve-fibre, not being greater than the faintest sound audible in a sound-proof room, is in ordinary circumstances imperceptible; in the fluctuating intensity of a beating note many fibres will be implicated at the maximum; at the minimum, relatively few. At a minimum of intensity which is not absolute some fibres will continue to conduct the series of impulses of the note, while others will at this instant discontinue, and the impulse preceding the interruption may evoke the displeasing sensation of a noise, whereas with slow beats, where the discontinuity in many fibres is spread over a longer time, the effect is not so, but pleasant. Hence with two primaries of nearly the same frequency we may hear at the same time beats and the beating note. When the interval between the primaries is sufficient for the frequency of the beats to be that of a real tone, we may in the same manner hear at the same time the separate primaries and either the beats or the beat-tone, or both the beats and the beat-tone. Further application of this principle will be found to offer a solution of other obscure problems in hearing.

W. PERRETT.

University College, Gower Street, May 20.

British and Foreign Scientific Apparatus.

MY attention has been directed to a letter appearing in the issue of NATURE for May 6 dealing with the subject of scientific apparatus. Your correspondents are extremely moderate in tone, but they do not state the class of apparatus to which they are referring.

Members of the association of which I have the honour to be chairman manufacture a large number of scientific apparatus, not only in glass and porcelain, but also other goods as well. Some of these were manufacturers in this country before the war, and proved by the quality of their products that they were able to stand against foreign competition; other members have entered the scientific trade only since the outbreak of the war, mainly at the request of the Government. The difficulties they have experienced have been extremely great, but they can prove that the quality of most glassware articles turned out is equal in many respects to that of articles previously imported from abroad.

Certain complaints have reached us; these have been most carefully investigated, and in many cases we found that the complaint dealt with glassware which was not manufactured by our members, but had been sold without any mark or badge of the manufacturer. Our members will be only too pleased to co-operate in every possible way with scientific workers, and look to them for the help necessary in establishing this "key" industry and placing it on a thoroughly sound basis.

As regards State aid, we do not want this in the form suggested, but rather we desire the creation of some method by means of prohibition whereby the industry will be enabled to establish itself, and at the same time the customer will not be penalised by being unable to get his material or the quantity of apparatus he desires. Under the form of prohibition which has been suggested, all orders for apparatus from abroad would have to come before a Special Committee of the Board of Trade. This Committee would

issue licences for all articles which were not made in this country either in sufficient quantity or of approved quality. At the present moment the rate of exchange is such that British manufacturers cannot compete even under the most up-to-date methods of manufacture, and it must always be borne in mind that this is a new industry which has not had time to establish itself or to get over the experimental stages of glass as an industry.

DOUGLAS H. BAIRD,
Chairman.

The British Chemical Ware Manufacturers' Association, Ltd., 4 Lincoln's Inn Fields, London, W.C.2, May 18.

Mortlakes as a Cause of River-windings.

MR. T. S. ELLIS asks us in NATURE of April 29, p. 264, to believe that the curves of a meandering river, instead of being wholly secondary features, are to a large extent primary, arising from the simplification of a "complicated network of channels." He admits, however, that such a network does not occur in existing rivers, and it will require more than deductive reasoning as to what should happen on a newly exposed land surface to prove that it belongs to any stage of their evolution.

On our sandy and muddy shores we have abundant opportunities for studying inductively the genesis of new stream-systems; and the general resemblance between these transient formations and the river-systems which we regard as youthful lends strong support to existing theory. In these primitive streamlets islands are not uncommon, but they are almost always of narrow lenticular form, with the lens-angles pointing up- and down-stream, and the lateral curves moderate. Save, perhaps, in a few exceptional cases, nothing approaching the sweeping curves of a meandering river is ever seen, and a whole volume of inductive reasoning goes to show that such curves belong to the stages of maturity and old age. How far the "primary consequent streams" approach and how far they deviate from straight lines depends largely upon the angle of slope; and this again, on our shores, is often conditioned, quite apart from the coarseness of material, by the rapidity of the tidal movements; for example, the drainage of the mud-*flats* of Poole Harbour is quite distinct from that of the mud-*banks* of the Wye near Chepstow; but there is surely sufficient ground for believing that regional uplift has sometimes been comparatively rapid, and in such circumstances straight consequent streams would be the rule

Even in Mr. Ellis's special case of Mortlake his conclusions are by no means free from objection In the first place, admitting the former existence of an island, Mortlake would lie at the head of it, and therefore quite outside the area of the "mort-lake" (as defined by Mr. Ellis) now represented by the Beverley Brook. Secondly, it is surely unreasonable to attempt to evolve primary laws from such obviously secondary conditions as we find on the flood-plain of the Thames.

Lastly, I should like to point out that, even when islands occur, their secondary nature is frequently obvious, and that there are many cases in which one of their limiting channels is due, not to the main river, but to a tributary captured by it. Jumièges, on the Seine, affords a fine example of such capture, but the island has become an isthmus. Between Datchet and Old Windsor the island and backwater ("mortlake") are retained. I am not in a position to say whether the Beverley Brook has been similarly captured and then set free again, but such a double change is not impossible.

HENRY BURY.

Mayfield House, Farnham, Surrey, May 1.

Science and the New Army.

THE two letters on this subject in NATURE of April 22 raise some points of considerable interest.

It seems clear that any attempt to train the main body of Army officers thoroughly in science and in scientific methods will be fruitless under present conditions, while it is even more certain that any attempt to train General Staff officers as scientific experts is extremely undesirable. It is, in fact, the duty of the General Staff to rely on its technical corps for advice, and it is unsound in principle and in practice for the General Staff to include within itself a separate body of experts.

On the other hand, the General Staff should possess a wholesome regard for the results which can be achieved by scientific methods, and this regard is all that is necessary to the General Staff, though the technical corps should be strengthened by the addition of scientific experts.

There appear to be three totally different Army requirements, namely:—

1. An organisation permitting the utilisation, so far as possible, of the services of scientific and technical men in time of war: (*a*) in the Army, through the Territorial Force and Officers Training Corps; and (*b*) outside the Army, as advisers in a civilian capacity.

2. An organisation which in peace time will keep the technical corps in close touch with the progress of science. This organisation would preferably be associated with the Research Department or Departments of the War Office

3 Training of the general body of Army officers and the General Staff in scientific methods.

No attempt should be made to convert General Staff officers into scientific experts, for the reasons given above; in the nature of things, the General Staff officer *must not* be a specialist.

There seems to be every desire on the part of men of science to assist the War Office to the best of their ability; it rests with the War Office to prove that it has a sincere desire to avail itself of the opportunities offered.

C. S. WRIGHT.

Waage's Phytochemical Synthesis of Phloroglucin from Glucose.

IT is generally stated that phloroglucin is formed by floating leaves in sugar solutions when exposed to sunlight. This phytochemical conversion of an aliphatic chain into an aromatic ring-compound is based on observations published by Waage in 1890 (*Berichte der deutschen botanischen Gesellschaft*, vol. viii., p. 250), which have found their way into nearly every text-book on the subject (compare, for example, M. Wheldale Onslow, "Practical Plant Biochemistry," p 7, which has just been published). The fascination of this simple experiment and its general importance to plant chemistry have made me repeat it every summer for the last fifteen years, but not in a single case, out of nearly eighty experiments, did I succeed in detecting even the slightest trace of phloroglucin. For the detection of phloroglucin I used the pine-wood test, as recommended by Waage, and also the bromine-water test after extraction with ether.

It seems to me, therefore, desirable that this very important experiment of Waage's should also be re-investigated by others interested in this question with the view of either definitely confirming or contradicting it.

M. NIERENSTEIN.

University of Bristol, May 8.

The Development of British East Africa.[1]

IT may be claimed for Lord Cranworth's volume that in a large measure it fulfils the author's main object of placing before intending settlers in British East Africa information and points of view which should be helpful to them. To this end the chapters dealing with agricultural and industrial prospects, primarily in the highlands of the Protectorate, furnish detailed information such as the most suitable areas as to soil and climate; the cost of land, labour, equipment, etc.; the requisite capital for various enterprises; and the return which may be anticipated.

There is one serious omission, however, in that no reference is made to the financial difficulty resulting from the enhanced exchange value of the rupee. This serious handicap to new settlers had not arisen when the author wrote "A Colony in the Making," from which he produced the book now under review as a revised edition; but, since the later volume was not published until 1919, it is surprising that the currency question was not dealt with as a new chapter, or at any rate referred to in the author's preface.

Lord Cranworth points out that the book is not an erudite work, but gives a few plain facts and suggestions for the guidance of those without experience of British East Africa. The usefulness of the book is enhanced by Lady Cranworth's contribution of a chapter giving not only hints on equipment for women, but also a description of the life in the highlands of East Africa, with its varied interests for women, and advice as to the suitability of the climatic and other conditions to women and children. The author himself devotes a chapter to the educational facilities at Nairobi and other centres, which should be helpful to intending settlers who are married.

A short history of East Africa, together with some notes on the native races and the effects of immigration from India, Arabia, and Somaliland, forms an interesting basis to the general description of subsequent developments and future prospects.

An ox being hyperimmunised to rinderpest. From "Profit and Sport in British East Africa."

Several chapters deal with big game and with sport and games of many kinds; those on big game furnish information as to the localities where various species are to be found, and how their presence affects the settler, while a chapter is devoted to beasts which the author would place in a black list as having many undesirable proclivities and nothing which may serve to counterbalance their disadvantages. Reproductions of Mr. J. G. Millais's "Buffalo" and his picture of animal life on the Loieta Plains are included in the illustrations.

To those interested in stock-raising an appendix giving notes on remedial measures against stock

[1] "Profit and Sport in British East Africa." Being a Second Edition, Revised and Enlarged, of "A Colony in the Making." By Capt. The Lord Cranworth. Pp. xvi+503. (London: Macmillan and Co., Ltd., 1919.) Price 21s. net.

diseases, compiled by the Chief Veterinary Officer of the Protectorate, should be read in conjunction with the author's chapter on cattle. With reference to measures adopted to combat the spread of rinderpest, there is an interesting illustration showing the method of hyperimmunising cattle.

The book concludes with a chapter detailing the assistance furnished by British East Africa and the sacrifices made by both Europeans and natives in furtherance of the military operations which resulted ultimately in the conquest of what is now known as Tanganyika Territory.

Those who, like Lord Cranworth, have the interests of British East Africa at heart will welcome this volume, with its purpose of bringing to the Protectorate an influx of recruits of the right standard requisite to further the development of its resources, particularly in view of the existing demand for the raw materials required in the reconstruction of the Empire's industries.

Weather Notes of Evelyn, Pepys, and Swift in Relation to British Climate.

By CAPT. C. J. P. CAVE.

THE interest in weather notes from old diaries lies in the fact that they may throw some light on the vexed question whether meteorological conditions in Western Europe are changing. The diaries of Evelyn and Pepys have been quoted by both believers and unbelievers in changing conditions, and it must regretfully be admitted that the question is, as yet, by no means easy to answer. Evelyn's diary extends from 1620 to 1706, but during this long period there are, on the average, only about eight weather notes to every three years. As a rule, we find only very outstanding phenomena recorded, such as serious droughts, great storms, or hard frosts. Evelyn's diary has, however, never been published in full, and it is quite possible that the complete diary may contain a great deal more information on the subject. Pepys's diary extends only from 1660 to 1669, and is, therefore, too short to enable us to draw any safe conclusions. His weather notes are, however, far more numerous than Evelyn's, there being remarks bearing on the weather on an average of sixty-two days a year. Like Evelyn, he mentions outstanding features, but he also frequently mentions the weather as it affected his movements or his health, so that we get a much better record for the few years during which Pepys kept a diary than we do for the longer period from Evelyn. Neither writer is by any means infallible in his recollection of past weather, and both can be confuted from their own writings regarding events that they describe as unprecedented in their memories.

The most significant facts from which to gauge weather conditions, in times before instrumental readings, are hot summers, droughts, wet spells, and cold winters. So far as hot summers are concerned, we have little to go on. Both writers complain of the heat at times, but the only really exceptionally hot summer seems to have been that of 1698, mentioned by Evelyn. Nor do we get very much ground to go on in droughts and wet spells. We are, therefore, restricted to cold winters, and especially to the freezing of the Thames, for evidence of any change in climate between the seventeenth century and the present time. The evidence was discussed by several writers in *Symons's Meteorological Magazine* in 1911 and 1912, and different writers came to diametrically opposite conclusions. Mr. Walter Sedgwick maintained that the intensity of falls of snow was likely to be exaggerated by the seventeenth-century diarists, for when roads were normally bad, traffic would have been far more seriously affected by snow than it is to-day. Mr. W. H. Dines, on the other hand, contended that when roads were always bad during the winter, "it was a matter of indifference whether roads were blocked by snowdrifts." It is also said that the number of references to snow in Evelyn's diary are very few, but it is quite certain that we do not find references to snow on nearly all the occasions when it occurred. In December, 1648, Evelyn says: "This was a most exceeding wet year—neither frost nor snow all the winter for more than six days in all"; but none of these six days are otherwise mentioned in the published diary. The winter of 1657–58 was extremely cold, and it is almost certain that there must have been snow; but none is specifically mentioned.

It is certain that the Thames in London froze more often in the seventeenth than in the nineteenth century, but some hold that this was due to the fact that the river was not embanked, and that Old London Bridge offered such an obstruction that the water above the bridge froze more easily than it does to-day. The Thames in London is recorded to have been frozen, or nearly frozen, on seven occasions during the period over which Evelyn kept his diary, and it is almost certain that it must have been frozen also in 1658. It is noticeable that the freezing in November, 1662, is mentioned by Evelyn, but not by Pepys, while the freezings of December, 1665, and January, 1667, are mentioned by Pepys, but not in the published diary of Evelyn. It seems as though the freezing of the Thames was not looked on as such a very out-of the-way event, while slight frosts or small falls of snow might pass unnoticed. There were, of course, winters when there was little or no frost or snow, but they were looked on as very exceptional, and caused much apprehension as likely to "threaten a plague," and fasts were ordered by Parliament to pray for "more seasonable weather."

From the evidence in Pepys's diary the present writer thought at first that "there seems no reason to suppose that the weather" in the seventeenth

century "differed much from that to-day,"[1] but a further consideration of Pepys's notes, taken in conjunction with those of Evelyn, has led him to modify his views, and he now thinks that, on the whole, there is a good case for supposing that the winters in the seventeenth century were more severe than they are to-day. Sir John Moore, it is true, maintained in a paper, "Is our Climate Changing?" read before the British Association (Section A) in 1908, that the British climate is not changing; his evidence is based mainly on observations during the nineteenth century, with some from the eighteenth; but the constancy of the climate during the nineteenth century does not seem to preclude a change having occurred since the seventeenth, nor does it follow that a change should be progressive.

There must, however, be a good deal more evidence in scattered letters or diaries that will in time throw more light on this important point. In Swift's "Journal to Stella," which extends only from 1710 to 1713, there are weather references on seventy-eight days a year. The period is short, but I think it bears out the contention that winters with little frost or snow were exceptional. On December 27, 1710, Swift writes: "Did you ever see so open a winter in England? We have not had two frosty days." This was probably a *façon de parler*, for at least two frosts are mentioned previously, and one fall of snow. By a frosty day it must be supposed that the diarists meant more than a slight morning frost of one or two degrees in the screen. If this is so, the warmth of the early winter in 1710 was not very exceptional, judged by present-day standards. December 27, it must be remembered, corresponds to January 8 new style, but in the last fifteen years during which the writer has kept climatological records there have been four, if not five, winters when there has been no frost worth speaking about until after the middle of January, in Hampshire at any rate, and these were probably as "open" as the winter of 1710.

Swift, on the whole, takes rather more interest in the weather for its own sake than does Pepys. He compares notes with "Stella" on the difference between the weather in Ireland and in London, but, of course, most of the references concern the weather as it affected him personally. There are many complaints of cold, wet, and heat, and Swift seems to have had a constitution that was much affected by hot weather. It is curious to find that bad weather is frequently made an excuse for dining with Mrs. Vanhomrigh at the time when Swift was beginning that acquaintance with her daughter "Vanessa" which was fraught with so much tragedy.

[1] Quart. Journ. Roy. Met. Soc., vol. xlvi., p. 68.

Optical Instruments in Industry.

OPTICAL instruments, which proved their worth in war, are now being more and more utilised in developing the arts of peace. A short account of some of the chief applications of these instruments to industrial requirements, especially the more recent uses, may therefore be not without interest at the present time.

Passing over the microscope with a brief reminder of its modern use, in metallurgy, for showing the structure of iron and other metals, one of the first instruments to note is the refractometer. In many chemical works this, in one form or another, is invaluable as a means of controlling the various operations, by reason of the simplicity of its manipulation and the rapidity with which the results are obtained. The refractive index suffices in numerous instances to determine the strength of chemical solutions. It is ascertained in a few minutes, and only a drop or two of liquid is required for the purpose if an instrument of the Abbe type is employed. No weighings are involved, and no calculations if the temperature is suitably controlled, so that liability to error is greatly minimised. The instrument is thus almost an ideal one for the control of works operations where the degree of strength or purity of a product is required to be ascertained by means of rapid tests, or where a process has to be stopped when the product has reached a certain stage. Specific gravity determinations or simple chemical titrations are often used in such cases, but the refraction method is always quicker, is generally more accurate, and sometimes possesses other marked advantages. Thus the strength of an aqueous solution of nicotine can readily be obtained, correct within about 0·1 per cent., by the refractometer, whereas the specific gravity method is of no value in this instance, and titration results are vitiated if other basic substances, such as ammonia, are present.

Acetic acid, acetone, ammonia, ammonium sulphate, carbolic acid, cream of tartar, glycerin, and saltpetre may be mentioned as products, made on a large scale, for which the instrument is useful. In the brewing industry the determination of alcohol, extract, and original gravity of beer is readily made by means of the refractometer. In the fats and oils industries, in the fractionation of petroleum products, in the distillation of tar oils, and in the manufacture of many pharmaceutical articles, the refractive index is a valuable aid for controlling the purity of the materials and finished products. It is useful also in the manufacture of various viscous mixtures or semi-solid pastes, in order to determine whether the constituents have been adequately mixed, and thus to obviate local excess or deficiency of the active ingredients.

The polarimeter is an instrument constantly in use for the evaluation of essential oils, whilst makers of starch products, tartaric acid, and alkaloids frequently have recourse to it, and a

specialised form of the appliance, the sacchari-meter, is practically indispensable in the sugar factory.

Mention must also be made of the simple polariscope in its application to the glass industry, where it is employed for detecting strains in glassware due to faulty annealing. Not infrequently glass articles, imperfectly annealed, are destroyed on the cutting-wheel after a good deal of time

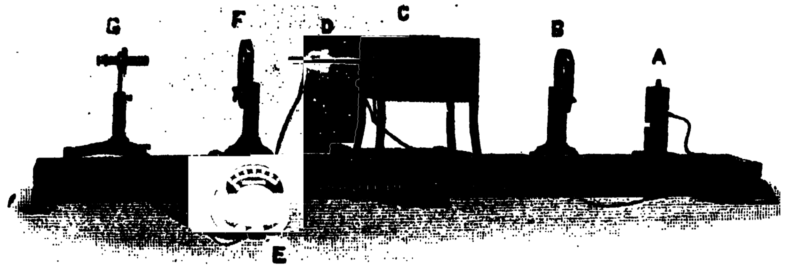

FIG. 1.—Twyman's apparatus for the determination of annealing temperatures. A, B, F, G, optical system; C, electrical furnace; D, pyrometer; E, temperature recorder.

has been spent on their partial decoration. Use of the polariscope to detect strains is not new; makers of optical glass have, naturally, long availed themselves of it; but as regards ordinary glassware the method has been brought more prominently under notice as a result of war conditions, and the "strain viewer" is now becoming more generally known in glass works. The principle involved is merely that of the well-known transmission of polarised light through crossed Nicol prisms when crystalline or semi-crystalline material is placed between them. Well-annealed glass leaves the field of the instrument practically uniformly dark; strained glass produces patches or bands of light, the intensity and colour of which give some idea of the amount of strain.

In this connection it may also be mentioned that certain other faults in glass can readily be detected by means of X-rays. This discovery has proved very useful in making the best qualities of optical glass, by preventing the use of material in which "air-blows" had formed.

Twyman's apparatus may also be noted here. It is used for determining the annealing temperature of glass (Fig. 1). The method evolved for this purpose is applicable also to metal objects, so far, at least, as the removal of stress is concerned. Trouble during the machining of metals such as manganese-bronze, owing to distortion through stress, might often be obviated by proper annealing of the articles.

Among recent developments, perhaps the most notable is the fact that the spectroscope, in one adaptation or another, is beginning to take a definite place as an adjunct to industry. This follows upon the progress which has been made in fitting the instrument to quantitative work. In fact, it is the spectrometer, rather than the spectroscope proper, which is proving its value to the manufacturer. Hartley's work on quantitative spectrum analysis, dating from the eighties of last century, may be regarded as the pioneer investigation. He showed that the ratios of the intensities of lines in the spectrum of an element do not remain constant whilst the quantity of that element is decreased, and he introduced the term "persistency" to indicate whether a particular line appears at a definite concentration of the substance emitting it—*e.g.* 1 per cent., 0·1 per cent., and so on, of the total material under examination. This work of Hartley's was followed by that of Pollock and Leonard in Dublin, and of Gramont in France—to mention only three names out of many. Meanwhile, the earlier forms of spectroscope have given rise to the more perfect "constant deviation" wave-length spectrometer

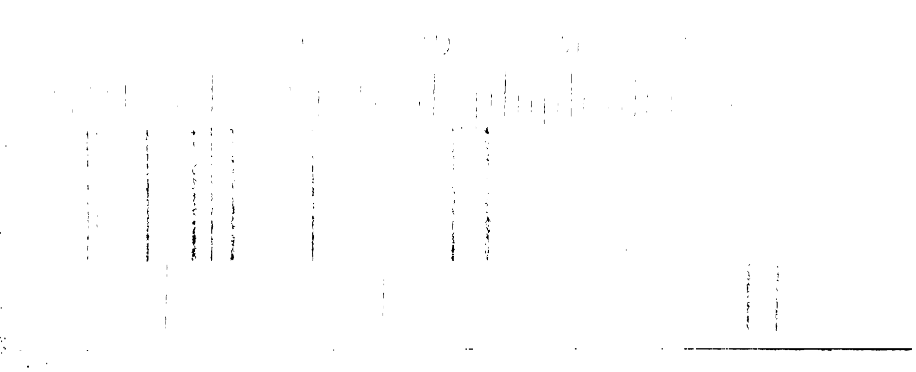

FIG. 2.—Print from negative taken on spectrograph with wave-length scale. Top strip, sample of reputed "pure tin." Middle strip, sample of commercial tin. Bottom strip, short exposure of copper spectrum. The presence of copper in the commercial tin is shown by the presence in the corresponding spectrum strip of the two copper lines at 3247 and 3274. A trace of copper is present in the "pure" tin.

and the quartz spectrograph, with the result that it is now practicable even to carry out quantitative analyses of metals by means of their spark spectra (Fig. 2).

Gramont uses two types of sparking apparatus (see *Comptes rendus*, 1918, clxvi., 95). In one of these the substance under examination is contained in a crater formed in one pole of the apparatus; in the second type the substance is fused in a platinum vessel, a spark being passed from a thin rod into the fused material.

This method has been used by M. Nicolardot in the chemical laboratory of the Technical Section, French Artillery, and according to Gramont it gives very satisfactory results in the control of chemical analyses. The spectrograph has also been for some time in use at the Bureau of Standards, Washington, for determining small quantities of impurities in tin and in the analysis of steel, especially as regards chromium and titanium. For estimating small quantities of elements such as niobium and molybdenum, the spectrographic method is, indeed, stated to be more trustworthy than chemical analysis.

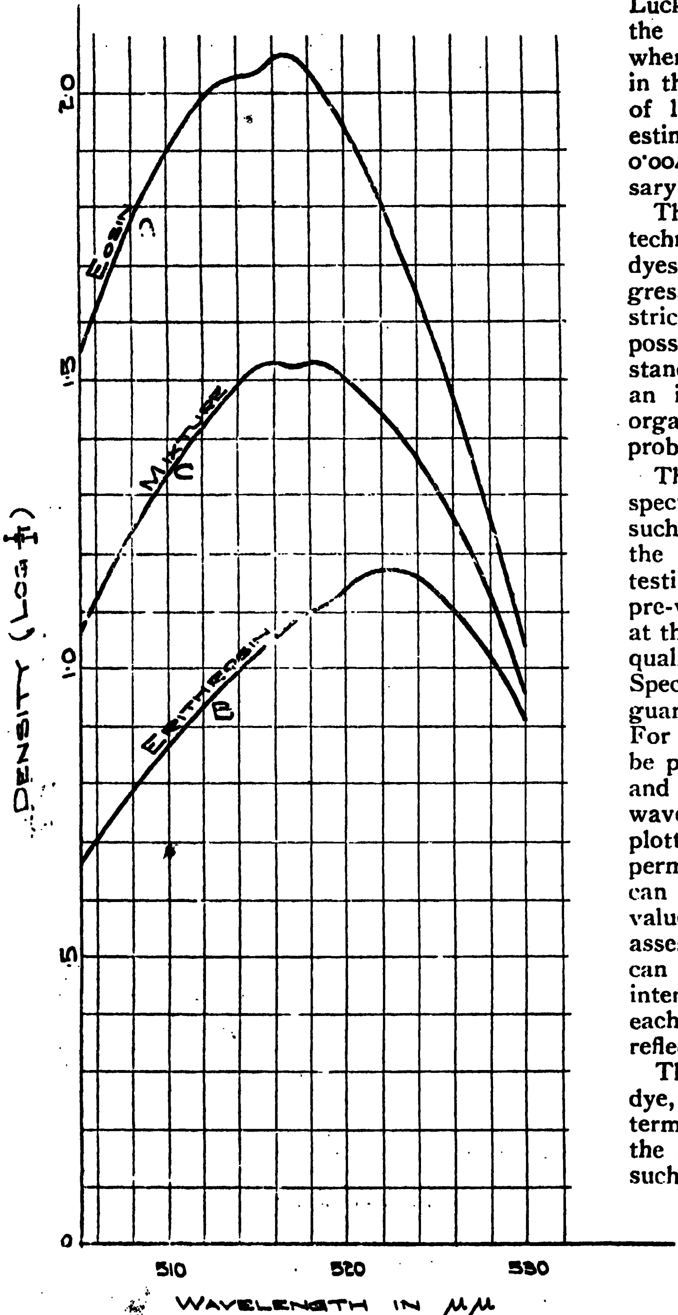

FIG. 3.—Curves plotted from results obtained in examining dyes with the spectrophotometer.

Another analytical method for metals has been described, depending upon a difference in volatility of the elements present. The authors (Hill and Luckey) use the "arc" discharge, and measure the time required for a given line to disappear when a known weight of the material is burned in the crater of the arc. Though this process is of limited application, it can be used for the estimation of lead in copper, within a range of 0·004 to 0·216 per cent., with the accuracy necessary for the work of a copper refinery.

The spectrophotometer, too, is now finding technical application, especially in connection with dyes. As the study of absorption-spectra has progressed, means for making the observations more strictly quantitative have developed also. The possibility of measuring the absorption of a substance for light of each wave-length is, in fact, an important addition to the resources of the organic chemist in dealing with certain technical problems.

The apparatus employed is a spectrograph or spectrometer combined with a suitable photometer such as the "Nutting" instrument. It is used in the control and analysis of dyes, the chemical testing of which is often a difficult matter. In pre-war days purchasers of dyes were very much at the mercy of foreign dye-makers as regards the quality and strength of dyes sent to them. Spectrophotometry can now be employed to safeguard the interests of the user in this respect. For example, a solution of known strength can be prepared from a trustworthy specimen of dye, and its colour-density determined for a series of wave-lengths by the spectrophotometer; a curve plotted from the results can then be kept as a permanent reference with which future supplies can be compared. Similarly the colour-producing value of a dye with various illuminants may be assessed by means of the instrument. Dyeing tests can be quantitatively controlled by comparing the intensity of reflected light from the dyestuff in each part of the spectrum with that of light reflected from a white surface.

The proportion of diluent substance added to a dye, or of two dyes in a mixture, may also be determined by reference to standard curves. Thus in the subjoined diagram (Fig. 3), A and B denote such curves for known strengths of eosin and erythrosin respectively, and C is a curve given by a mixture of the two substances, in unknown proportions. By taking ordinates for two suitable wave-lengths, two equations can be formulated, from which the proportions of the two dyestuffs in the mixture are calculated. From these examples the value, actual and potential, of the instrument to the dyeing industry will readily be understood.

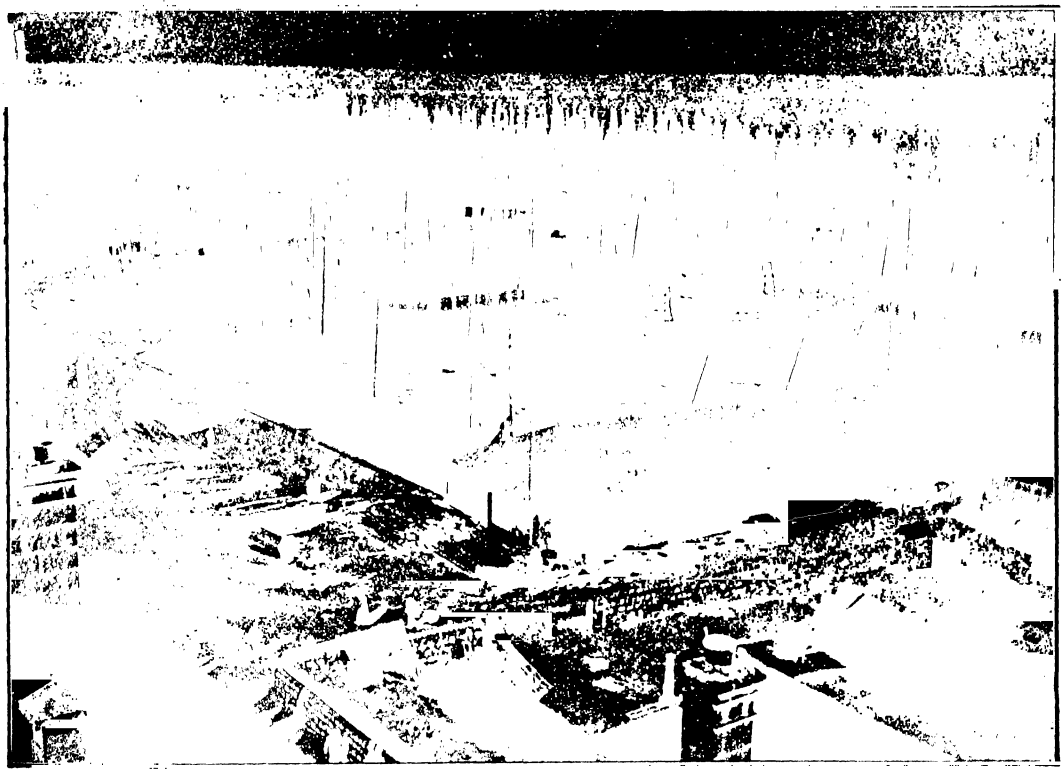
Of other technical uses to which special instruments are applied, a brief mention must suffice. Thus in the iron and steel industry certain rapid

sorting-out tests can be made with the grating spectrometer and with the quartz spectrograph, whilst the projection comparator is a valuable aid, in engineering, for the ready optical gauging of interchangeable parts, such as screw-threads.

An important development, too, is the use of radiography in the examination of metals; but this need not be dealt with here, as it was referred to in an article on "Industrial and Medical Radiology" in NATURE of February 26.

The British Sea Fisheries.[1]

THE latest book on the sea fisheries comes most opportunely at a time when everyone interested in these matters is looking for a policy. For the last two years a multitude of committees and conferences have been considering a situation that has become acute as the result of war conditions, but which was rapidly developing even in 1913. There was then a great recrudescence of interest in the longshore and inshore fishermen; there were the perennial questions of the impoverishment of the fishing-grounds and of how this might be averted; and there were indications, even then, of troublesome problems relating to the distribution and marketing of the fish caught.



The herring fleet in Fraserburgh Harbour. From "The Sea Fisheries."

There is no doubt at all that it is these latter difficulties that have been accentuated by the circumstances of the last two years. Such things as landing facilities, railroad and motor transport, market accommodation, cold storage and curing in order that gluts of fish might be utilised, cost of new construction, labour troubles, etc.—these are the matters that immediately and personally concern those engaged in the industry. The conditions are very different from those that obtained half a dozen years ago. Then there was practically no control; but one Government Department now has to do with railway facilities; another fixes wholesale and retail prices; while others again have to do with regulations of many kinds. The result is, for the present at all events, a confusion which is apparent to almost everyone.

Under our economic conditions the profit-factor in industry is still the dominant one. The bulk of the fish landed are caught in order that they may be sold so as to yield a "return" on the capital invested; otherwise no fish would be landed except the small fraction taken by individually owned boats and longshoremen who work for a living and sell their fish for whatever it will bring. How is the deep-sea fishing industry to be carried on so as to yield a sufficient profit?

[1] "The Sea Fisheries." By Dr. J. T. Jenkins. Pp. xxxi+299. (London: Constable and Co., Ltd., 1920.) Price 24s. net.

Long ago we should have left *that* question to the trade itself, but it is now clear that a policy of *laissez-faire* is no longer possible. The people must have food. The State has already taken partial control, and the logical development of such conditions seems to be the public organisation of the means of distribution and, if so, the control of profits as well as of prices.

Dr. Jenkins does not deal with these latter-day economic questions. The conditions are transient, and it is quite impossible for any man to get trustworthy information tending to elucidate them. Probably no administrator or office is big enough to deal adequately with the difficulties of the moment, and the situation must be left to resolve itself in the near future. On the other hand, it would be hopeless to attempt to study it without reference to the other fundamental questions which we have indicated. Is there really an impoverishment of the fishing-grounds, and, if so, what restrictions are necessary that this may be avoided? Regulation being necessary, what is the best form of administration? What is industrial efficiency as applied to the fisheries? Judged by the ratio of fish caught to the man-power employed, the inshore and long-shore fishermen are inefficient, and their methods wasteful. But, that being so, is it in the national interest that a prolific, hardy, and versatile stock should be allowed to decline? What, above all, are the nature and value of the information which we use in order to decide upon these matters?

Even in present circumstances, then, there are fundamental problems that must be considered before we tackle those of the moment, and it is these with which the author deals. He gives a summary of the methods of sea-fishing employed in Great Britain, and an historical sketch of the development of the trawl- and herring-fisheries. This is based on prolonged literary research and is very well done. There are a summary of the legislation applicable to the industry, a short account of the British and foreign administrations, and a *résumé* of the chief results of the fishery commissions of the strictly modern period. A well-selected bibliography should enable the reader to follow the various discussions in greater detail than that which falls within the scope of the book. It is very proper that considerable weight should be given to the scientific side of the subject, and in his introduction the author deals most conveniently with the situation of the industry at the close of the war period, especially with regard to the reconstruction of the national administrations and the development of an adequate machinery for scientific and economic investigation. Altogether, the work is one that must be considered quite essential to anyone who seeks to discover, beneath the confusion of the moment, the natural conditions upon which the continued development of the national sea fisheries, as a whole, must necessarily depend.

J. J.

Notes.

THE annual meeting of the British Science Guild will be held at the Goldsmiths' Hall on Tuesday, June 8, at 3 p.m. Lord Sydenham, president of the Guild, will deliver an address on "Science and the Nation," and the president-elect, Lord Montagu of Beaulieu, will speak on "Some National Aspects of Transport." The adoption of the report on the Guild's work since the last annual meeting will be moved by Lord Bledisloe, and seconded by Sir Gilbert Parker. The Guild is extending its activities in several directions, and all who believe in the application of scientific knowledge and method to national affairs of every kind should give it support. Tickets of admission to the annual meeting may be obtained upon application to the Secretary, British Science Guild, 6 John Street, Adelphi, London, W.C.2.

AT the Imperial Entomological Conference to be held in London on June 1–11, the subjects to be discussed, although mainly relating to agriculture, are not the less on that account of great general interest, and ought to make a wide appeal. Mr. H. A. Ballou, just returned from an investigation of them in Egypt, will read a paper on "Cotton Pests," a subject which he has long studied in other parts of the Empire. Dr. R. S. MacDougall will read one on "Insects in Relation to Afforestation," which is a subject greatly needing attention in our own country at the present day. There will also be read important papers on the special insect pests of tea and other crops, as well as on the local insect pests of various places within the Empire; and amongst other subjects for discussion "The Education of Economic Entomologists" should prove attractive, the more so as Profs. Maxwell Lefroy and Sydney J. Hickson have promised to give their views upon it. The meetings are all to be held at the rooms of the Linnean Society, Burlington House, and visits have been arranged to Oxford, Cambridge, and the Rothamsted Experimental Station, Harpenden. "The Work and Finances of the Imperial Bureau of Entomology" will be considered at the business meeting on the first day, when, doubtless, there will be nothing but greatly deserved praise for the work, and very serious consideration in regard to the finances. It is to be hoped that as an outcome the Bureau will be enabled to carry on, unhampered and unimpaired, the extremely valuable work it has done during the seven years of its existence.

A PAN-PACIFIC Scientific Congress has been organised to meet at Honolulu on August 2–20. The programme of the congress is directed by the Committee on Pacific Exploration of the U.S. National Research Council, and the chairman is Mr. Herbert E. Gregory, director of the Bishop Museum at Honolulu. The papers to be read will deal with the present status of knowledge of anthropology, biology, geology, geography, and related sciences so far as they refer to the Pacific Ocean, and will place emphasis on the research work which it is desirable to inaugurate. The significance and bearing of the research work on other fields of study will be dealt with in considerable detail. It is suggested that in the working out of

the problems only the ability and interest of the scientific workers should be taken into account, nationality and institutional rivalry being submerged for this purpose. Co-operation would eliminate unnecessary duplication of money and energy, and point the way to the best use of funds now available and to the utilisation of further endowments. The director of the museum is also organising a party consisting of an ethnologist, archæologist, botanist, and necessary staff, which will be stationed in 1920–21 at the Marquesas, Austral, Tongan, and Hawaiian Islands to establish standards of the physical form, material culture, traditions, and languages of the Polynesians which may serve as a basis for the determination of the significance of changes produced by the overlapping of other races. A similar expedition is projected for 1921–22 westward to the Caroline Islands, to determine through what place or places the Polynesians reached their present settlements. Funds sufficient for one year's work, contributed by Bayard Dominic to Yale University, have been placed at the disposal of the museum trustees. The urgent need for a scientific study of the fast-changing Pacific is plain. It has been recognised in Australia, where a committee, appointed by the Universities of Melbourne and Sydney, has reported in favour of the establishment of fellowships in Pacific studies. If America studies eastern Polynesia, Australia still has Papua and the Western Islands.

THE preliminary programme of the annual meeting of the British Association for the Advancement of Science, to be held at Cardiff on August 24–28, has been issued from the offices at Burlington House. The previous meeting in that city was held in 1891, and there has been no meeting of the association in Wales since that date. The present president, Sir Charles Parsons, will hand over his office to Prof. W. A. Herdman, professor of natural history in the University of Liverpool, who will give in his presidential address a general survey of oceanography, and deal in detail with certain special problems and recent investigations, with particular reference to sea-fisheries, a topic not only of prime interest in connection with the food supply of the country, but also of special concern to the ports of the Bristol Channel. The programme announces a discourse at one of the general evening meetings by Sir Daniel Hall, of the Ministry of Agriculture, on "A Grain of Wheat from the Field to the Table," another pregnant subject at the present time. Sir Richard Glazebrook, lately Director of the National Physical Laboratory, will also deliver a discourse. A scientific exhibition in connection with the meeting is announced to be given in the museum exhibition room at the Cardiff City Hall, where the general reception room for the meeting will also be established. The sections will meet mostly in the University College and the Technical College, which, with the City Hall, belong to the fine range of public buildings which surround Cathays Park. Scientific excursions will be organised in connection with the work of several of the sections. A civic reception by the Lord Mayor is announced, as is also a garden party for members, given by Lord Treowen, president of the National Museum of Wales (which has its headquarters at Cardiff). Among other fixtures is a special service in St. John's Church, Cardiff, on the Sunday after the meeting, at which Dr. Barnes, Canon of Westminster, will preach.

PRINCE ALBERT will preside at the Royal Aeronautical Society's Wilbur Wright lecture, which will be delivered at the Central Hall, Westminster, on June 22, at 8.30 p.m., by Commander Hunsaker, upon the subject of "Naval Architecture in Aeronautics."

THE Academy of Natural Sciences of Philadelphia has conferred the Hayden memorial medal for 1920 on Prof. T. Chrowder Chamberlin, professor emeritus of the University of Chicago, in recognition of his distinguished services to geological science. This medal is presented every three years for distinguished accomplishments in geology or palæontology.

THE twenty-fifth annual congress of the South-Eastern Union of Scientific Societies will be held at Eastbourne on June 2–5. On the evening of Wednesday, June 2, the president-elect, Sir Edward Brabrook, will deliver his presidential address. Other items in the programme are:—The Glaciation of the South Downs, E. A. Martin; First Steps in a Local Survey, C. C. Fagg; Recent Discoveries in Insect Mimicry, Prof. E. B. Poulton; Report of Mosquito Investigation Committee; and Migration of Lepidoptera, R. Adkin.

THE possibilities of cotton-growing in South America are discussed at length by Mr. G. McC. McBride in the *Geographical Review* for January (vol. ix., No. 1). Up to the present South America has produced annually scarcely 2 per cent. of the world's total output. Mr. McBride shows reasons for believing this could be greatly increased. The principal increase must come from the eastern highlands of Brazil. In the São Paulo region it is already competing with coffee, which suffers more than cotton from frosts. Labour and transport are the factors which limit its growth at present, but as these are gradually overcome Brazil will be able to export cotton on a considerable scale. Other possible cotton lands occur in the plains of northern Argentina and Paraguay, and in the coastal valleys of Peru.

TOWARDS the end of March last a meeting was held in Brussels of the scientific committee of the Solvay International Institute of Physics, and it was resolved, upon the recommendation of the executive committee, to resume the work of the institute, which had been interrupted by the war. New physical councils will be summoned from time to time, similar to those formed in 1911 and 1913. The president referred to the debt which the scientific committee owed to Dr. R. B. Goldschmidt, of Brussels, for the services rendered by him to the institute during the early years of its foundation. The members of the committee were Prof. H. A. Lorentz (president), Haarlem; Mme. Curie, Paris; Sir W. H. Bragg, London; M. Brillouin, Paris; Prof. H. Kamerlingh Onnes, Leyden; Prof. Knudsen, Copenhagen; Prof. A. Righi, Bologna; Sir Ernest Rutherford, Cambridge; and Prof. E. Van Aubel, Ghent.

MAJORS MCKENDRICK AND MORISON have investigated statistically the occurrence of cases of influenza on shipboard, from which they deduce a mean incubation period in this disease of 32·7 hours, some 90 per cent. of the cases having an incubation period within two days (*Indian Journal of Medical Research*, vol. vii., No. 2, p. 364).

IN a general review of influenza in *Medical Science: Abstracts and Reviews* (vol. ii., No. 2) the influenza epidemic of 1918–19 in Switzerland is surveyed. It is estimated that there were $2\frac{1}{2}$ million cases. The case mortality was 1·1 per cent.; 65 per cent. of the cases occurred between fifteen and forty-nine years of age, and only 5 per cent. in persons of fifty and more. The total deaths were 17,575, a much heavier death-roll than that caused by other epidemic diseases.

ATTENTION is directed in a paper by Mr. Mottram and Mr. Clarke (*Archives of Radiology and Electrotherapy*, No. 237, April, 1920) to the reduction in the number of the white blood corpuscles in those handling radium for curative purposes, a reduction amounting to $\frac{3}{4}$–$\frac{2}{3}$ of the normal number. They estimate that the physician-in-charge receives daily about 1·4 per cent. of the total radiation received by a patient during a course of treatment for cancer, and in ten weeks the same quantity of radiation as the patient.

THE Committee on Food and Nutrition of the National Research Council, Washington, U.S.A., has just issued a report on meat and milk in the food supply of the nation which gives some interesting facts on the relative values of these two important dietary substances in comparison with the value of the food required to produce them. The Committee supports the British estimates on the same subject, viz. that the good milch cow returns 20 per cent., the poor milch cow 12 per cent., and the good beef steer only 6 per cent. of the energy-value of the food consumed. Crops grown on a given area may be expected to yield four to five times as much protein and energy for human consumption when fed to dairy cows as when used for beef production.

AN address on the work of the Medical Research Committee was delivered by its secretary, Sir Walter Fletcher, to Members of Parliament at the House of Commons on March 9, and has been published in pamphlet form by the Research Defence Society. The history of the committee was first briefly sketched. Some 50,000*l.* a year has hitherto been devoted to the advancement of medical research, but the Treasury has announced that in the immediate future 125,000*l.* per annum is to be allocated for this purpose. Sir Walter Fletcher then described some of the researches that have been prosecuted by means of these funds. A disease, bilharziasis, due to a parasitic worm, is very prevalent in Egypt. Its life-history was unknown, and Dr. Leiper, of the London School of Tropical Medicine, was sent out to investigate. He found that the bilharzia worm passes part of its life-cycle in certain fresh-water snails, from which larval forms hatch out; and these constitute the infective agents. They soon die, however, unless they enter the human host, so that water kept for twenty-four hours is safe. This work cost less than 500*l.*, but bids fair in time to eradicate bilharziasis. Trench nephritis, a kidney disease, was very prevalent during the war. Investigations into its causation indicated that it is probably of an infective nature. Means were devised by which the efficiency of the kidney could be gauged, and it was possible to decide which of the thousands of cases at the base hospitals were likely to grow worse and should be sent home, and which could probably soon go back to duty. The same tests have been employed since in judging claims for pensions based upon supposed damage to the kidneys. By this means it is estimated that the Pensions Ministry has saved, during the first year, no less than 150,000*l.*; yet the total cost of this piece of work was somewhere between 2000*l.* and 3000*l.* Sir Walter Fletcher put in a plea for the better remuneration of scientific research, and the address was followed by an interesting discussion.

IN the *British Journal of Psychology* (vol. x., March) Mrs. S. Brierley discusses the present attitude of employees to industrial psychology. She finds, in talking to working-men, much opposition to the suggested introduction of psychological methods into industry—an opposition which cannot be dismissed as characteristic of the more ignorant and less skilled workman. Several reasons for this attitude of mind are considered, of which the most vital seems to be the not unreasonable fear that the introduction of these methods will inevitably lead to an increase of monotony and a diminution in the possibility for initiative or creative work on the part of the individual worker; some of these so-called scientific methods do seem to imply that the manager is to be the brains of the machine, and the worker merely the muscles. It is unfortunately only too true that some enthusiastic exponents of these methods have allowed their enthusiasm to limit their point of view to increased production, and in so doing they have lost sight of the effect on the individual worker. The problems of monotony, mechanisation, specialisation, and self-government must be considered not only as bearing on increased output, but also as affecting the whole development of the worker; work must offer an outlet for the healthy satisfaction of the creative impulse. The author raises many problems connected with present-day industry and shows what psychology as applied to industry has to face before it can win the whole-hearted support of the workers. The paper should prove interesting to all whose scientific work brings them into contact with individual workers in industry.

SINCE the early experiments of Cuénot, Castle, Miss Durham, Little, and others on the inheritance of coat-colour in mice, these animals have been a favourite subject for the study of spotting as well as of self-colour. In a recent paper by Sô and Imai (*Journal of Genetics*, vol. ix., No. 4) the authors distinguish two factors concerned in spotting, one of which (D) is epistatic to self-colour, which it modifies to the "Kasuri" pattern characterised by fine silvered

markings. When the recessive spotting allelomorph (S′) of self-colour (S) is present with the epistatic factor, a white animal with dark eyes known as "Daruma" (snowman) is produced. Mice which are homozygous for D fail to develop whether S or S′ is present in addition. D is, therefore, a lethal factor, and can only appear in the heterozygous condition, as is well known to be the case with yellow mice. By this analysis it is shown that a varied and apparently continuous series of stages from dark-eyed white through spotting to self-colour depends upon two pairs of factors.

MR. T. W. VAUGHAN furnishes a comprehensive account of the American Tertiary, Pleistocene, and Recent coral-reefs in Bulletin 103 of the U.S. National Museum, pp. 189–524, 1919, as the fore-part of a paper describing fossil corals from the zone of the Panama Canal. No naturalist—and in this term we of course include the geologist who strives to understand the past—can afford to overlook this important summary of recent work. Some readers may be startled by the statement that "the theoretic possibility of the progressive change of a fringing reef into a barrier, and later into an atoll, according to the Darwin-Dana hypothesis, may not be denied, but no instance of such a transformation has as yet been discovered." But the author again and again emphasises the upward growth of coral-reefs in keeping pace with the submergence of the platforms on which they first arose. The discussion of these platforms and of their pre-Glacial age is full of interest; but Mr. Vaughan rightly points out that the question of their modes of origin does not affect the question of reef-growth. Murray's theory of solution to account for lagoon depths is regarded as "entirely disproved," and every credit is given to Dr. Guppy and Admiral Sir J. Wharton for their views on the relation of reefs to submarine platforms. The corals that result in barrier-reefs flourish, as Guppy urged, at some distance from a shore, because they are there removed from deleterious sediments; the reef thickens, as Wharton perceived, by submergence of its base. In the case of Australia, though not as a general proposition, Mr. Vaughan believes that this submergence can be accounted for by the rise of water during "deglaciation." The effects of drift-currents in developing and controlling the form of atolls on an open platform may be regarded as well established.

THE Italian State Department has now resumed publication of its Reports of the Aeronautics Experimental Institution (*Rendiconti dell' Istituto sperimentale aeronautico*). No. 1 of the new series just to hand contains an exhaustive article on the treatment and preservation of wood. The first part of this important monograph deals with the botanical aspect of the subject; the second part with the theory of timber preservation, including drying and seasoning; the third part with the practical side of timber seasoning and impregnation with preservatives; while part iv. is devoted to methods of testing (both physical and mechanical).

MEASURES are being taken to reorganise and extend various scientific services in French Indo-China. M. Aug. Chevalier, writing in *La Géographie* for April (vol. xxxiii., No. 4), gives some account of the plans. The agricultural, forest, and survey departments had fallen into neglect when the present governor-general in 1917 took steps to revive them. Several experimental agricultural stations and agricultural schools have been founded, and this year work was begun on the building of a central scientific institute at Saigon, to which the agricultural service of Indo-China and the botanic gardens at Saigon are to be attached. The institute will conduct experiments in the growth of rubber, coffee, tea, and rice; study the flora and products generally of Indo-China; and conduct researches on plant diseases. It is also proposed to start a marine station. The Government has provided funds for a scientific library and the issue of a monthly agricultural bulletin.

No. 23 of the Proceedings of the Dutch Meteorological Institute is devoted to three papers by Miss A. van Vleuten on the possibility of accounting for the daily variations of the earth's magnetic field by a system of electric currents external to the earth and the currents within the earth's surface induced by them. In 1889 Schuster concluded that such was the case. Since that date both Fritsche and Steiner have examined the data available, and concluded that it did not support the hypothesis. In view of this difference of opinion Miss van Vleuten has again analysed the daily variation of the field, and resolved it into an external and an internal part. The two show that the principal terms of the Gauss expansion do not support the hypothesis, although the higher and less important terms are in agreement with it. In a further paper the author, by comparing the terms of the potential calculated, first, from the north component, and, secondly, from the east component of the field, shows that the daily variation of the field does not possess a potential, although it is, of course, always possible to deduce part of it from a potential.

THE physiological aspect of flying at high altitudes engages the attention of Dr. Guglielminetti in *Génie Civil* for March 20. The experiences of mountaineers, balloonists, and airmen who have flown to great heights are reviewed in turn. From tests carried out in the laboratory, and from the experience of Mosso and Agazotti (of Turin), Dr. Guglielminetti is inclined to the opinion that the physiological disturbances caused at altitudes below 8000 metres are due to anoxyphemia, and above 8000 metres to acapnia. While the use of respirators having suitable reducing-valves controlled automatically by the varying pressure at different altitudes would no doubt afford a fairly satisfactory solution, the better way lies in the design of suitable closed cabins in which the air-pressure is maintained constant by compressing the air taken in from outside. M. Louis Breguet has already suggested a design of aeroplane in which the pilot and passengers would be so enclosed. The excess of air necessary for the engine at high altitudes would probably be supplied by a turbine driven by the exhaust gases such as has been suggested by Prof. Rateau,

THE report of the Council of the Illuminating Engineering Society, presented at the annual meeting on May 11, contains an interesting record of the past session's work. Papers and discussions dealing with photometry, camouflage, colour-matching, motor-car head-lights, and lighting conditions in mines have been arranged, the last in co-operation with the Council of British Ophthalmologists and the Royal Society of Medicine. The various committees working under the society, notably that conducting an inquiry into eyestrain in kinemas, afford evidence of similar co-operative effort. Special attention has been devoted to industrial lighting in relation to health and safety, and it is hoped that before long general statutory provision for adequate lighting will be introduced into the Factory Acts. The society hopes now to be able to resume its participation in the international treatment of illumination, and is represented in the person of its hon. secretary at the congress of the Royal Institute of Public Health taking place this month in Brussels. Following the presentation of the annual report, a paper on portable kinema outfits was read by Capt. J. W. Barber, several novel forms of apparatus being shown.

THE work of Willstätter and his collaborators has imparted considerable interest to that branch of biochemistry which includes the formation of anthocyanins in plants. A suggestive paper on the subject is contributed to the April issue of the *Biochemical Journal* by O. Rosenheim. This author has isolated in a crystalline form the red pigment of the young leaves of the grape-vine, and has shown that it is most probably identical with oenidin, the non-sugar component of the pigment of the purple grape. This is the first instance on record in which the red pigment of leaves consists of free anthocyanidin. The vine-leaves have been shown to contain also a colourless modification of the pigment, possibly in combination with a carbohydrate or other complex. For this compound the general name "leuco-anthocyanin" is suggested; it is converted into anthocyanidin by strong acids. The only representative of the family Vitis characterised by the production of free anthocyanidin is the European species, *Vitis vinifera*, and it is pointed out that this biochemical test may prove useful in the investigation of genetic problems.

AN interesting paper by Eiichi Yamasaki on "The Chemical Kinetics of Catalase" has recently appeared in the Science Reports of the Tôhoku Imperial University (vol. ix., No. 1). The property formerly attributed to all enzymes of accelerating the decomposition of hydrogen peroxide is really a specific property of catalase, which is contained as an impurity in most enzyme preparations. The catalase used by Yamasaki was obtained from the edible sprout of a certain bamboo, *Phyllostachys mitis*, Riv. The velocity of decomposition of hydrogen peroxide by catalase is, in general, proportional to the concentration of the enzyme and of hydrogen peroxide, but the activity of the catalase decreases in the course of the reaction. As to the cause of this decrease in activity, the author can only conclude that it is due to the substrate and product of reaction, hydrogen peroxide and oxygen; and the rate of decrease is approximately proportional to the principal reaction. The decrease in activity is not to be attributed to change in concentration of hydrogen ions. It has already been found that in a very dilute solution of hydrogen peroxide and a comparatively concentrated solution of catalase the relative activity increases in the first stage and then decreases gradually. This behaviour may be attributed to the facts (1) that the ordinary reaction would be carried out at a rate somewhat higher than that which is calculated according to a first-order reaction; (2) that the rate is retarded with hydrogen peroxide and oxygen in ordinary cases; (3) that such effects are observed only in the course of reaction in very diluted solutions, because the concentration of both the substrate and the product are very small, *i.e.* the velocity constant has a maximum value; and (4) that the retardation proceeds with the measurable velocity, which is approximately proportional to the principal reaction.

THE Rotary Club of London, composed of about three hundred members, each representing a different trade or profession, and connected with twenty-five other rotary clubs in other parts of the British Isles, has undertaken the urgent and important work of endeavouring to find posts for demobilised men out of employment. We are asked to direct attention to this most praiseworthy task and have much pleasure in doing so. Thousands of capable officers and men who were on active service during the war are now seeking employment, and particulars of vacancies of any kind may usefully be sent to Mr. Edward Unwin, jun., at the "Rotary Room," Horrex's Hotel, Norfolk Street, Strand, London, W.C.2.

MR. H. MARTIN LEAKE, Director of Agriculture, United Provinces, India, is publishing through Messrs. W. Heffer and Sons, Ltd., "The Bases of Agricultural Practice and Economics in the United Provinces, India," in which the history of agriculture is traced; the fundamental facts of agricultural practice and economics are described; the lines upon which agricultural practice is likely to develop are brought out, and emphasis is laid upon the fact that recent advances in scientific knowledge have made it possible for directed, as opposed to undirected or empirical, methods to be employed. It further indicates the weaknesses of the present economic system, and develops the idea of co-partnership in the land between landlord, tenant, and Government.

MESSRS. DULAU AND CO., LTD., 34 Margaret Street, W.1, have just issued a catalogue (No. 82) of an important botanical library recently purchased by them, the volumes in which are now offered separately. The works listed number 593, and many are scarce. The catalogue is one likely to interest all students of botany, and copies may be had of Messrs. Dulau upon application.

Our Astronomical Column.

ASTRONOMICAL ANNOUNCEMENTS BY WIRELESS TELEGRAPHY.—Prof. Kobold, editor of *Astr. Nachrichten*, and director of the Centralstelle, delegated the latter work to Prof. Strömgren, Copenhagen, during the war, but has now resumed it, and announces in *Astr. Nach.*, 5044, that arrangements have been made for the distribution of astronomical information by wireless telegraphy from the Nauen station. Such messages will bear the signature "Obs.," and it is suggested that institutions that wish to receive them should make arrangements with the wireless station nearest to them that receives Nauen messages. It is hoped that they will make a contribution to the cost of the service. The idea of using wireless in this manner is certainly a good one, and might be of great service in the case of such unexpected phenomena as the outburst of novæ, where early observations are of special value.

THE ASTROGRAPHIC CATALOGUE.—This great undertaking, begun a third of a century ago, is still far from completion, many of the observatories that undertook to collaborate having dropped out, from financial or other reasons. Their zones were afterwards allotted elsewhere, and one of the new observatories (Hyderabad) may be mentioned in particular for its praiseworthy energy. The late director, Mr. R. J. Pocock, unhappily died without seeing the work completed; but thanks to the Nizam's generosity the work is continuing under his successor, Mr. T. P. Bhaskaran, who has just published vol. iii., containing measures of rectangular co-ordinates of 58,743 star-images on plates with centres in decl. $-19°$. The form of publication is similar to that in the Greenwich and Oxford catalogues.

TIDAL FRICTION AND THE LUNAR AND SOLAR ACCELERATIONS.—Dr. H. Jeffreys has a paper on this subject in the Monthly Notices for January, in which he quotes Major G. I. Taylor's result in Phil. Trans., A, ccxx., that tidal friction in the Irish Sea accounts for 1/56th of the required dissipation of energy, assuming that the moon's secular acceleration is 10·5″ per century, which is 4·4″ above the amount calculated from planetary action on the earth's orbit. The accelerations are here measured, as is customary, by the space gained at the end of a century. Dr. Jeffreys uses the more strictly logical system of the velocity gained, and, consequently, doubles the value of the acceleration. He gives a list of the seas that seem likely to contribute to the tidal effect, and concludes that they are capable of producing the whole of it. The tidal acceleration of the moon is the difference of two terms: (1) the apparent acceleration due to the slackening of the earth's rotation, and (2) the actual retardation due to increase of distance. In the case of the sun only (1) is present, though there may be further acceleration if the earth is travelling in a resisting medium. Dr. Jeffreys finds for the solar acceleration 1·56″ on his system—that is, 0·78″ on the usual system.

Dr. Fotheringham has rediscussed the accelerations from all available ancient observations. He finds 10½″ for the moon, and 1″, or somewhat more, for the sun. The corresponding period for the large empirical lunar term is 260 years. Prof. Turner finds that this period agrees well with the periods deduced from Chinese earthquake records and from those of Nile floods. He also confirms it by statistics of tree-growth, derived from a study of their annual rings. He suggests that the earth is pulsating in this period with consequent alteration in its rotation, which produces an apparent fluctuation in the moon's motion, and smaller ones in that of the sun and planets.

The Iron and Steel Institute.

THE annual meeting of the Iron and Steel Institute, held in London on May 6-7, was rendered noteworthy by the fact that the incoming president was Dr. J. E. Stead. It is somewhat remarkable that Dr. Stead has not been elected to this office before. He has been engaged in metallurgical work for fifty years, has reached the age of seventy, and no metallurgist in this country holds a higher international reputation. He has carried out a considerable number of researches of first-rate importance which are remarkable for their suggestiveness and technique, and he possesses in a striking degree the confidence and respect of those engaged in the industry. The explanation, however, is forthcoming in the opening sentences of his address, from which it is clear that he was invited to fill this office some years ago, but refused as he did not consider he was qualified, to use his own words, "to accept such an exalted position." It is quite safe to say that this misgiving has never been shared by anyone else. Dr. Stead finally yielded to the strong representations of his fellow-members on the council, and his acceptance of the office of president has been received with widespread gratification by the institute.

His presidential address is an attempt to pass in review the progress made in the ferrous industries during the past fifty years. This proved to be a gigantic piece of work, and it is not surprising to learn that Dr. Stead found more trouble in condensing than in collecting the voluminous data so as to bring them within the limits of an address. Even so, it turned out that he was not able to read more than one-third of it. The address is divided into a series of sections which deal successively with the blast-furnace, the puddling process, science in the foundry, the basic Bessemer and basic open-hearth processes, electric furnaces, the production of sound ingots, the recognition of science, the advent and progress of metallography, the application of science to the ferrous industries, the encouragement of science, and technical education. Within the limits of this article it is only possible to touch briefly on the subject-matter of three of these sections.

(1) *Blast-furnace Practice.*—It appears from the accumulated experience of this branch of the industry that no object is gained by increasing the capacity of the furnace above 30,000 cubic feet, and that its working is best controlled by having a separate blowing engine for each furnace. Increased output per furnace can be achieved by widening the diameter of the hearth and increasing the volume of the air blown in. The gases issuing from the furnace-top should be conserved by the adoption of the double bell or some similar system. The maximum proportion of their calorific value should be used by freeing them from dust, controlling the proportion of air for their combustion, and maintaining a low exit temperature. Coke-ovens should be close to furnaces and the coke handled as little as possible after it leaves them so as to avoid the production of "fines," and should be sufficiently hard to resist crushing. Fine coke disorganises the regular working of the furnace and reduces the output of pig-iron. It should, therefore, be sieved off and either used for other purposes or briquetted, if the process be not too costly, and then charged into the furnace. Dr. Stead concludes that there is sufficient evidence to show that given efficient gas-engines it is advisable to use them in preference to steam-engines. One of the still unsolved problems is the utilisation of the heat carried out of the furnaces in the slag. Inasmuch as the gas and the heat obtained from the

blast-furnaces and coke-ovens exceed the requirements of the blast-furnaces, he regards it as probable that in cases where coke-ovens, blast-furnaces, and steelworks are grouped together sufficient gas will be available to do all the heating at the steelworks without using any raw coal.

(2) *Electric Furnaces.*—The electro-thermal steel furnace, which up to 1914 had produced only a very small proportion even of the higher grades of steel, was developed with great rapidity in this country during the war. Germany led in this branch of the industry, and most of the German electric steel was made by refining basic Bessemer steel. Furnaces of 30 tons capacity were used for this purpose. The U.S.A., Italy, and France were all ahead of England in production. To-day the U.S.A. leads, followed by Germany and England. It is stated, however, that the actual number of furnaces and the amount of power used are greater in England than in Germany. By the end of 1918 no fewer than about 140 furnaces of all types were in use in this country, with a production of 150,000 tons per annum. During the war the output in these furnaces was principally used for making steel for bullet-proof plates, aeroplanes, motor-cars, armour-piercing shells, and steel helmets. Stainless steel is being made in increasing quantities, as are also nickel-chromium and other alloy steels. The significant statement is made that on the Tyne electro-thermal steel is being manufactured at a price which can compete with the acid open-hearth steel, since cheap power is available from coke-oven gas. A great advance is foreshadowed in Dr. Stead's reference to the melting of steel *in vacuo*. Mr. Albert Hiorth, of Christiania, has designed an induction furnace of this type in which the steel is melted and then cooled. Afterwards it is removed and cut up into sections for forgings. It is stated that in this way steel free from honeycomb and gases is obtained. While it is probable that this process is likely to be, for the present, applied only to the highest qualities of steel, experience may indicate the desirability of its extension to other varieties later on.

(3) *Technical Education.*—Dr. Stead finally puts in a powerful plea for the better education of the technical staffs and workmen engaged in the industry. He mentions that many years ago he discussed and formulated a scheme with the late Mr. Andrew Carnegie whereby there was to be established in every industrial centre an institute which could be used as the headquarters of local technical societies, consisting of metallurgists, engineers, electricians, chemists, and others. At this centre proceedings of technical societies and all technical publications were to be assembled. Indexes of subject-matter would be prepared by a competent staff, and supplied to the general managers of the various industries. After many years' discussion a step in this direction has been taken in the Middlesbrough district. Suitable premises have been obtained, which are being reconstructed to meet local requirements. The sum of about 10,000*l.* has been subscribed, and there are promises of annual subscriptions. This, however, is only a beginning, and Dr. Stead, who has nothing if not vision, contemplates an annual contribution from the iron and steel industry for the purpose of making the scheme adequate. He suggests a contribution of 0·1 per cent. on the capital invested, or 1 per cent. on the actual dividends. Taking the former at, roughly, about 250,000,000*l.*, the annual charge would be 250,000*l.* A fund of this magnitude should be sufficient in his opinion to enable technical institutes to be established and maintained in the eight principal iron- and steel-making districts and in London, and to carry on their work with a "fair degree of efficiency." It is to be hoped that this suggestion of Dr. Stead's will be vigorously taken up by his council, and a serious attempt made to bring it to fruition.

H. C. H. CARPENTER.

The University of London.

GOVERNMENT OFFER OF A SITE.

AT a meeting of the Senate of the University of London, held on May 18, the Vice-Chancellor, Dr. Russell Wells, reported that the Chancellor, the Earl of Rosebery, had received from the President of the Board of Education, Mr. H. A. L. Fisher, a communication in the following terms, dated April 7:—

"The Government have watched with sympathetic interest the efforts which the universities have been making to fit themselves for the task that the period of reconstruction imposes on them, and to take advantage of the opportunities for extending their usefulness which are offered by the steadily growing public recognition of the national importance of a good system of university education. Nowhere are the opportunities more favourable than in London; for as the capital city of the Empire, with the unmatched facilities for many branches of study and research which its great national collections, hospitals, and public institutions provide, London has always attracted a large number of students, not only from all parts of the United Kingdom, but also from overseas. The war has deepened the general sense of Imperial and international solidarity and has spread more widely an understanding of the mutual benefits which the different peoples derive from drawing closer the relations between their educational systems; and it is accordingly to be anticipated that in the near future many more university students will be coming to London from our Dominions and Colonies and from foreign countries. This will inevitably place a very serious strain upon the teaching resources of the University of London and will add considerably to the already grave difficulties of organisation by which the University has long been confronted. The Government have, during the past year, sanctioned large increases in the grant to the teaching institutions included in the University of London, as in the grants to the other universities and colleges throughout the country, and no doubt these additional grants should go some way towards enabling the University to meet its increased responsibilities. The mere increase of the grants to individual colleges will not, however, by itself dispose of the special problem which London University has to solve, and the Government are accordingly prepared to take a further step which they consider likely to prove of very material assistance to the University at this critical stage of its development.

"It has seemed to the Government that this is a suitable time at which to make an offer which they have long had under consideration and which they think should help to remove a good many of the administrative difficulties involved in the housing of the University headquarters in the Imperial Institute at South Kensington. The Government are now in a position to acquire a site of about 11½ acres behind the British Museum, and they offer to devote it gratis and in perpetuity to the provision of a site for new headquarters of the University and for colleges and institutions connected with it, including King's College, whose premises in the Strand are now

inadequate for its needs. It would be out of place for me to enlarge on the advantages to be expected from securing the concentration of the headquarters of the University and its two incorporated colleges on a single site, in a quiet residential quarter close to our greatest National Library and Museum, and capable of expansion in the future as the need may arise. The merits of this site, as of other alternative sites which have from time to time been suggested, have, I know, been the subject of much discussion by the friends of university education in London, and I have no doubt that the University is fully apprised of the considerations which need to be weighed. I have no desire to persuade the University against its will. No one recognises more fully than I do the right of universities to control their own destinies and shape their own policies. The responsibility for accepting or declining the Government's offer must rest wholly with the University, which alone is in a position to estimate how far the proposal I communicate to you is likely to advance what it conceives to be its true interests. The view of the Government is, I think, sufficiently indicated by their willingness to provide for the University a site of great value in the heart of London, at a time when there is no temptation to incur expenditure upon any but objects of first-rate urgency and importance.

"It had at one time been my hope that the Government would be able to offer not only the site of which I have spoken, but also the buildings for the new University headquarters: the Government have, however, reluctantly come to the conclusion that, while they are prepared to make such provision as will secure the University from loss in respect of maintenance charges on the new University headquarters, the state of the national finances did not justify their undertaking to provide the cost of the buildings themselves from public funds. They feel that in a matter in which the honour and dignity of the City of London are so nearly concerned, the University can look with confidence to the generosity and public spirit which have always marked the citizens of London: it can do this with the greater assurance that recent years have shown an increasing readiness upon the part of the great business community to respond to appeals for University purposes.

"I am aware that a matter of such importance to the University needs to be fully discussed, and that I cannot fairly expect an immediate answer to the Government's offer. At the same time the University will understand that the Government are naturally anxious to know as soon as possible whether their offer will be accepted or not, since, if it should be declined, they propose to make early use of the site for other purposes. I have, therefore, to ask that the University's answer may not be unduly delayed."

The matter was referred to a special committee for consideration and report as speedily as possible.

Genetic Studies of Drosophila.[1]

NO single animal has provided such a rich field for discovery in genetics as the little fruit-fly Drosophila (usually known as *D. ampelophila*, but now called *D. melanogaster*), and in this large and handsomely illustrated volume Prof. Morgan and his collaborators bring together the results of some of their recent work upon it. Of the four parts into which the book is divided, the most interesting is the first, dealing with the gynandromorphic specimens that have appeared in Prof. Morgan's and Dr. Bridges's experiments, and including a most valuable summary and discussion of gynandromorphism in other animals. In Drosophila it appears that about one individual in every 2200 is gynandromorphic, but these gynandromorphs are most varied in their combination of male and female characters. A considerable proportion of those described are bilateral, with male secondary sex-characters on one side and female on the other; a smaller number are "fore and aft"; while the majority are irregular mosaics, most often with a preponderance of female characters. It is a remarkable fact, however, that in Drosophila, contrary to what is usual in animals of other groups, the two gonads are always of the same sex—doubtless, as the authors point out, in consequence of the very early separation of the primitive germ-cells in the Diptera. As a result of this, it may happen that a fly is externally almost entirely of one sex while containing germ-cells of the other sex, so that Nature here confirms the conclusion reached by Meisenheimer and by Kopeč from transplantation experiments, that the sex of the gonad in insects has no influence on the secondary sexual characters. Flies externally chiefly male, but having ovaries instead of testes, court normal females, but attract males.

The authors believe that in all but very exceptional cases gynandromorphs of Drosophila are derived from fertilised eggs which would normally produce females, *i.e.* from eggs containing two X-chromosomes, and that the male portions arise from cells in which one X-chromosome has been lost through an abnormal mitosis in one of the early segmentation divisions. The evidence for this conclusion is that in almost every instance the sex-linked factors borne (according to the chromosome hypothesis) by the two X-chromosomes introduced from the parents are distributed as might be expected between the male and female portions of the fly. For example, a wild-type female (heterozygous for eosin eye and miniature wing) was crossed with an eosin-miniature male. A gynandromorph among the offspring was female on the left side, with red eyes and long wing, while the right side was male with eosin eye and miniature wing. The explanation offered is that elimination of the maternal X-chromosome on the right side allowed the recessive eosin-miniature characters borne by the remaining X-chromosome to appear. Morgan's earlier hypothesis of the production of gynandromorphs by the entrance of two spermatozoa into the egg, and Boveri's of the division of the egg-nucleus before conjugation with the sperm-nucleus, are excluded by the fact that the non-sex-linked characters borne by the two parents are not divided between the parts showing different sexes. In respect of these characters, all parts of the gynandromorph, whether male or female, bear the dominant characters, whether they are introduced by the male or female parent. The analysis of these gynandromorphs thus gives important confirmation to the theory of chromosomes as bearers of hereditary characters. It is remarkable, in this connection, that although elimination of the paternal and maternal X-chromosome is equally common, evidence for the elimination of other chromosomes, which would give mosaics in characters unconnected with sex, is very rarely obtained.

Analysis of the records of gynandromorphs in other groups of animals shows that most are susceptible of the same explanation. In a few cases some other hypothesis, such as that of a binucleate egg, must be invoked. It should be noted that in part i. there

[1] Contributions to the Genetics of *Drosophila melanogaster*. I. "The Origin of Gynandromorphs." By T. H. Morgan and C. B. Bridges. II. "The Second Chromosome Group of Mutant Characters." By C. B. Bridges and T. H. Morgan. III. "Inherited Linkage Variations in the Second Chromosome." By A. H. Sturtevant. IV. "A Demonstration of Genes Modifying the Character 'Notch.'" By T. H. Morgan. Pp. v+388+12 plates. Publication No. 278. (Washington: Carnegie Institution of Washington, 1919.)

are several slips and misprints; on plate ii., Figs. 4 and 5 are transposed, according to the description; on p. 28 the word "visible" appears to be a misprint for "recessive"; and on p. 86, l. 26, "female" is printed for "male," etc. But apart from these slips and the rather inconvenient arrangement of the subject-matter, the work is the most valuable on the subject of gynandromorphism with which we are acquainted.

Space does not allow of more than a brief reference to the other three parts. Part ii. discusses in detail all the mutant characters that have occurred in "the second chromosome," *i.e.* those characters belonging to the second linked group which are not sex-limited (sex-linked) in inheritance. Full data of crossing-over ratios are given, and on the basis of these a map of the chromosome is constructed, like those previously published for the X-chromosome. Part iii. deals with inherited linkage variations in the same group, and it is concluded that two factors, the position of which in the series is determinable by their linkage relations, reduce the amount of crossing-over between certain factors without altering their sequence in the series. Part iv. describes the isolation by selection of a factor which affects the extent of development of the character "notch" in the wing, and proves that change resulting from selection is due, not to an alteration in the factor for "notch," but to the presence of a distinct modifying factor. It is also shown that Castle's hypothesis of contamination by heterozygosis is untenable.

Finally, it is impossible to read the facts presented in this volume without being impressed by the great strength of the evidence for Morgan's theory that Mendelian factors are borne by chromosomes and arranged in definite sequence within them. Difficulties remain, but a theory which enables predictions to be made and verified cannot lightly be disregarded.

L. DONCASTER.

The Conservation of Fuel.

IN view of the importance of national economy in our fuel reserves, it is not surprising to find that Sir Dugald Clerk selected the subject of the conservation of fuel in the United Kingdom for the James Forrest lecture which he delivered at the Institution of Civil Engineers on April 20. The coal raised in 1913 was about 287·4 million tons, of which 189 million tons were retained and consumed here. The total coal reserves at 2 per cent. per annum increase will be exhausted in about 250 years, but fuel will be so expensive long before that time has elapsed that we shall be hard pressed to maintain the existing population. A return to the agricultural civilisation of 1750 would require the reduction of our population to one-third. It is of the utmost importance to study the engineering problems arising.

A great part of the lecture was taken up in criticising the figures given by the Coal Conservation Committee. It will be remembered that this Committee advocated the establishment of large turbo-electric stations at about sixteen centres, and the covering of the country with a network of mains capable of supplying our whole power needs by electric motors. By this scheme the Committee expected to save 55 million tons of coal on power alone. Many competent electricians and capable motive-power engineers have the gravest doubts as to the accuracy of the data presented, and as to the outcome of the ambitious scheme advocated. The Committee adopted the figure of 5 lb. of coal per horse-power-hour as the present consumption; Sir Dugald gave estimations arrived at by two different methods: one of 3·9 lb. per b.h.p.-hour and another of 4·05 lb. per b.h.p.-hour. The first value is based on a census of production data corrected by allowing for steam production other than for motive power, and for an error in total h.p.-hours as determined by the Committee. The second value of 4·05 lb. is estimated by considering the average of many typical steam engines. Taking the whole of the facts into consideration, and assuming electricity in the future to be used for the generation of power and light only, then a reduction to 1·56 lb. of coal per b.h.p.-hour would give a possible saving of not more than 37½ million tons of coal per annum. The saving of 55 million tons expected by the Committee is, in Sir Dugald Clerk's opinion, based on fallacious reasoning.

The Committee in its report clearly intends also to generate heat, and expects to do so with economy superior to the existing systems of coal and gas combustion. Sir Dugald went into the question of the comparison of gas with electricity for domestic heating, and arrived at the figure of 43·6 per cent. of the heat used at the gasworks as the proportion which the consumer receives at his premises; taking the efficiency of the gas at 42 per cent., the final efficiency, referred to the heat consumption at the gasworks, is $43·6 \times 0·42 = 18·3$ per cent. In electric heating the consumer receives 11·7 per cent. of the heat consumed in the thermodynamic transformation at the super-station, and using this with an efficiency of 59 per cent., the consumer obtains in his apparatus $11·7 \times 0·59 = 6·9$ per cent. of the heat units consumed at the generating station. Assuming the gasworks to be abolished, and electric generating stations to be expanded so as to supply current for heat supply at the same generating efficiency as for power, and taking all facts into consideration, Sir Dugald estimates that the whole assumed saving on power will be lost, and that 68·6 million tons of coal per annum will be consumed instead of 67·5; he therefore considers that the super-stations will not justify their existence, that the Government scheme is wrong, and that the sweeping conclusions arrived at by the Coal Conservation Committee are unjustifiable.

Sir Dugald gives some methods of saving fuel which are immediately applicable. Great changes are now in operation throughout the gas industry due to the adoption of the thermal unit standard for sale. In a few years the majority of gasworks will deliver to the consumer in the form of gas 75 per cent. of the whole heat of the coal, and the improvements in gas apparatus, etc., are so great that the efficiency of use of the gas will rise from 42 to 55 per cent. He estimates that a saving of 4·8 million tons of coal on the present consumption will result from these changes. On the assumption of the complete displacement of coal in households by gas, we should use only 17·5 million tons instead of [illegible] millions.

Mr. D. Brownlie's figures for coal consumed in boiler furnaces were quoted. If boiler attendants be better trained, and masters take some pride in obtaining best efficiencies, a saving of 4 million tons per annum would result. Collieries consume about 17 million tons per annum in boiler furnaces at an average efficiency of 55·5 per cent. If this be raised to 75 per cent., the saving on this item would be 4·4 million tons per annum.

The notion of the great gain to be expected from very large steam turbines is held to be quite erroneous. Even with the most modern plant an increase in power per turbine from 10,000 to 100,000 kilowatts only reduces the steam consumption from 9 to 8·5 lb. per kilowatt-hour. A recent examination by Sir

Dugald of the limits of thermal efficiency of gas and oil engines shows that 45 per cent. b.h.p. may be obtained in the near future. Sir Charles Parsons at the same time prepared an estimate of the limiting efficiency of the steam turbine as 28 per cent. Steam, internal-combustion, and gas engineers welcome the free competition with electricity supply, but consider that any attempt to crush out the smaller power units by a great Government scheme will act against the best interests of the country as to both coal conservation and economy in cost.

Sir Dugald also referred to the principle of heating towns by utilising the exhaust steam from steam turbines in central stations, and to Lord Kelvin's proposal to heat rooms by means of reversed Carnot cycle engines. By making full use of our water-power, three million horse-power could be added to the work of the country without consuming any additional coal

Buddhism in the Pacific.

AT a meeting of the Royal Anthropological Institute on Tuesday, May 18, Sir Everard im Thurn, president, in the chair, Sir Henry Howorth read a paper on "Buddhism in the Pacific." The paper discussed the disintegrated distribution of the Polynesian race, and the occurrence, especially in the Hawaian archipelago and that of New Zealand, of two of its factors which are separated by the whole length of the Pacific Ocean, one occurring in the extreme north and the other in the extreme south, and separated by an intervening area occupied largely by Melanesians. The two factors in question agree very closely in language, while they differ materially in the art and form of the objects which they use. Inasmuch as the Maoris almost certainly migrated to their present quarters at the beginning of the fifteenth century, this is the only way to account for the virtual identity of their speech with that of the Hawaians, and the general character of their ornamental work with that of the Melanesians. The Hawaians, on the other hand, present us with a series of objects, *i.e.* helmets and cloaks, made of feathers which, in their form and colour, differ entirely from those made by other members of the Polynesian race. They agree in an extraordinary way in colour and form with those of the Reformed Lamaists of Tibet, who, like other Buddhists, were great travellers and evangelists at a time when Chinese and Japanese vessels, as has been so completely proved in recent years, were traversing the Indian Ocean and visiting the whole of the eastern archipelago at least as far as New Guinea, and apparently even reaching New Zealand, where many years ago a very interesting bronze figure was found.

Sir Henry Howorth quoted instances of the drifting and wreckage of Chinese and Japanese vessels on the central and eastern Pacific during the time which has elapsed since Europeans first visited that ocean, and also the tradition of the Sandwich Islanders that several Japanese and Chinese ships had been wrecked among them in early times. It was not wonderful, therefore, that we should find their kings and gods adopting the stately dress used by the Lamas, the colours of which they imitated in feathers. All the details of the helmets exactly equate, while the cloaks are ornamented with patches of red on yellow or yellow on red, just as the Lamaist cloaks are, in the latter case in pursuance of the injunction of their founder that their cloaks must be ragged and patched.

In the interesting discussion which followed the reading of the paper, Dr. Glanvill Corney cited examples, some of which had come under his own observation, of the drifting of boats with native crews for long distances in the Pacific, and pointed out that the Polynesians were always ready to put out to sea. The Chinese had it on record that Buddhists visited Mexico at a very early date. The similarity shown by the helmets and cloaks of Hawaii and Tibet was very striking, and the explanation offered by Sir Henry Howorth was most probable.

Mr. Ray said that he himself for some years had been of the opinion that certain elements had been carried into Polynesia at least from Malaya, if not from farther—possibly Japan. The characteristic of the Polynesian was that he was very prone to imitate anything which took his fancy, as, for instance, European hats had been imitated. The Cambridge Expedition to the Torres Straits had found a club which was clearly an imitation of a Loyalty Islands club.

Mr. Hocart said that in dealing with the wanderings of the Polynesians too much stress had been laid on drifting, but deliberate purpose should be more emphasised. There was among the Polynesians a distinct passion for finding out new lands.

Dr. Forbes adduced as evidence of early movement Chinese objects which he had seen taken from Peruvian graves which were certainly pre-Inca in date.

Sir Everard im Thurn, in bringing the discussion to a close, said that Buddhist monks might well have accompanied the early voyagers in the Pacific. His attention had recently been directed to the question of the Hawaian helmets, and he wished to point out that the native peoples of the Pacific were very fond of making head-coverings for use on ceremonial occasions. They paid great attention to the ornamental dressing of their hair, and if their hair were not suitable for this purpose they made artificial hair out of grass seed. He himself had brought back from Fiji an example of a native wig used in a ceremonial dance, which was now in the Pitt Rivers Museum at Oxford. It was probable, therefore, in view of this particular tendency, that the Hawaians would take readily to copying the head-dress of the Buddhists. This particular form of head-dress or helmet was not confined to Hawaii; objects ornamented with men's heads wearing head-dresses like those of Hawaii occurred in Hermit Island, near New Ireland.

Astronomy at Oxford during the War.

WE have recently received from Prof. H. H. Turner, of the Oxford University Observatory, a collection of papers published during the years 1914–19. These for the most part are reprints from the Monthly Notices of the Royal Astronomical Society, and represent researches carried out during this period by Prof. Turner and various members of his staff, including several volunteer workers who have rendered some valuable assistance. It is, of course, impossible adequately to discuss a miscellaneous collection of papers such as this in any detail, but there are several outstanding features of interest which call for special remark.

In the first place, a considerable number of the papers is devoted to an important research of Prof. Turner's on "A Proposal for the Comparison of the Stellar Magnitude Scales of the Different Observatories taking Part in the Astrographic Catalogue." This was first outlined at Paris in 1909, the proposal being: "That the number of images recorded under each unit of the magnitude scale be counted and tabulated." The chief objects in view were to detect systematic errors of scale at the various collaborating observatories, and to test Prof. Kapteyn's conclusion that the Galaxy is relatively richer in faint

stars than the remaining parts of the sky—a theory upon which some doubt had been cast by earlier work of this nature. The method, although of extreme simplicity, has certainly proved efficient for the first of these objects, and various systematic errors of scale have been clearly exhibited. With regard to the second object, an examination of the ratio of the number of faint stars to bright in the various regions investigated appeared at first to negative Prof. Kapteyn's conclusion; but, although this ratio was not found to vary with galactic latitude, certain changes were detected in different parts of the sky. Prof. Turner has thus been led to the interesting conclusion that regions of "obscuration" exist which tend to obliterate the fainter stars, and these regions appear to form a spiral in the heavens, the central line of which is approximately given by the equation

$$\alpha + 3{\cdot}66\delta = 247^\circ,$$

where α denotes right ascension and δ declination. There appears to be a fairly sharp boundary to this "spiral of obscuration" on the side of smaller R.A. in the northern hemisphere, and on the side of greater R.A. in the southern hemisphere.

Another very valuable piece of work is represented by a series of papers on "Baxendell's Observations of Variable Stars," edited by Prof. Turner and Miss M. A. Blagg. A very considerable amount of painstaking work must have been expended on this task of revising and editing Baxendell's observations of some twenty-three long-period variables. The greater part of the work appears to have been done by Miss Blagg, and the result as a whole is certainly a most valuable contribution to the study of this particular branch of astronomy. In connection with this subject we may also mention two papers by Prof. Turner "On the Classification of Long-period Variables," in which the alternative classifications of the author and of the Rev. T. E. R. Phillips are discussed and compared at some length. Both methods are considered to be useful, and a suggestion is made that some stars might pass from one of Phillips's groups to the other during the course of their evolution. This latter idea is more fully discussed in the particular case of W Cygni, which appears to be changing from Phillips's Group I. to Group II.

There are many other shorter papers of considerable interest, but these are too numerous to be noted here individually. The whole collection pays ample tribute to the energy and resource with which work has been carried out at the observatory during the trying period of the last few years. Apart from the many difficulties directly resulting from the war, there have been other troubles with which the staff has had to contend. In particular, we regret to note the decease of the caretaker, Mr. J. Mullis, who had been with the observatory since its erection in 1874. There is at present no second assistant or resident computer, and Prof. Turner and his staff must certainly be congratulated on the way in which the work has been carried on in the face of these and numerous other difficulties.

D. L. E.

The Alligator Pear.

THE cultivation of the Avocado or alligator pear is the subject of articles by Mr. W. G. Freeman and others in the Bulletin of the Department of Agriculture, Trinidad and Tobago (vol. xviii., part 3). The Avocado (*Persea gratissima*), a member of the family Lauraceæ, is a pear-shaped fruit with a large central stone, the amount of covering flesh varying considerably according as the kind is good or poor. It is one of the most important of the fruits which have become widely distributed since the discovery of the New World. It is probably a native of tropical America, and was introduced at an early date into the West Indies, where it is now naturalised. Sir Hans Sloane, in his "History of Jamaica" (1707–25), gives a long description of the tree and its fruit, and Dr. Patrick Browne (1756) is eloquent on the flavour of the latter and the esteem in which it is held. The edible portion of the fruit varies from a little under one-half to more than three-quarters of the weight of the whole, according to the thickness of the rind and the relative size of the seed. Its food-value is mainly due to its high fat content, which in some varieties approaches that of the olive, and is especially high in the fruit grown in Florida and California.

Although so long cultivated in the West Indies, yet little attention has been given until recently to the selection and propagation of good varieties. It is an extremely variable plant, and the method of selecting seeds from trees bearing the best fruit and of high productiveness gives uncertain results, as the varieties do not come true from seed. But by budding or grafting from good varieties these may be fixed, and by this means poor trees will be converted into good varieties. Mr. Freeman suggests the probability of a seedless Avocado being obtained, as occasional seedless fruits have been reported from the United States and Honolulu. The Avocado needs no very special care in cultivation, and does very well on the poor soil of parts of the northern range in Trinidad. Budding has been practised at the St. Clair Experiment Station for the last four years, and the curator, Mr. R. O. Williams, gives details of the operation. The method is the same as that generally adopted for roses and citrus. The full-grown tree is fairly free from insect pests, but the plant is more susceptible in early stages and when recently budded. Mr. F. W. Urich describes the various insect pests and means for combating them. A more serious disease which attacks the fruit is the so-called anthracnose, very closely related to the fungus which causes anthracnose of the mango. In the case of fruits packed for export this disease causes complete rotting of the whole consignment. Repeated sprayings with Bordeaux mixture are necessary to prevent its development.

The Improvement of Grassland.[1]

IT is too often the case that grassland is left to take care of itself, and that no steps are taken for its improvement. Even where manuring is carried out it is usually confined to occasional dressings of farmyard manure; little or no use is made of artificial fertilisers, and the beneficial effects of lime upon the herbage are far less widely known than they should be. The consequence is that much of the finest pasture and meadow land in the country is carrying only a second- or third-rate herbage simply from lack of knowledge of the most effective treatments to bring about improvement. For the education of public opinion in this respect nothing is more useful than demonstration plots, and the Ministry of Agriculture and Fisheries has issued a most valuable and comprehensive pamphlet outlining schemes of experiments suitable for this purpose. The schemes intended for farmers are simple in character and direct and practical in their object, while those drawn up for the agricultural colleges and institutes deal with experiments requiring considerable attention and supervision.

[1] "The Improvement of Grassland: Suggestions for Demonstrations and Experiments." Miscellaneous Publications No. 25. Ministry of Agriculture and Fisheries.

As a preliminary, the necessary tables are given to enable the manures used to be standardised to ensure uniformity of treatment so far as possible, and the method of noting and reporting the results is clearly outlined. It is recommended that the attention of farmers should be devoted to the improvement of the various classes of grassland on different types of soil, and particulars are given for the manuring of meadow hay, "seeds" or rotation hay, and pastures of different grades. Emphasis is laid on the value of liming experiments, which should be carried on at the same time as the manurial tests.

The attention of agricultural colleges and institutes is directed to the need for various experiments other than manurial trials. Grazing trials properly carried out would provide valuable information as to the best methods of dealing with pasture land, and mechanical operations are suggested to show the effect of mole-draining, cultivation, breaking, and reseeding. In addition, it is suggested that a good deal of attention might profitably be directed to a consideration of the seeds used for sowing down, with regard to the permanence of different varieties, the most suitable mixtures for leys and for renovating permanent grass, and to the possibility of harvesting supplies of seed.

The pamphlet is so suggestive and so broad in its scope that it should find its way into the hands of all interested in grassland, and it is much to be hoped that the official nature of the publication will not prevent it from reaching the general farming public.

W. E. BRENCHLEY.

Levelling Errors.[1]

A DEPARTMENTAL paper lately published by the Survey of Egypt contains an interesting investigation of a systematic error which has been found to occur in the levelling carried out in Egypt and in the Sudan. The effect of this error, which has the same sign over all kinds of ground, acts in the direction of making the backstaff reading systematically too small and the forestaff reading too great. Movement of the staves or level and other sources of error having been eliminated, the author draws the conclusion that the effect of refraction is not wholly removed by keeping the distances between the level and the staves equal in the conditions under which the work is done. Precise levelling in Egypt is carried out in the winter months and during about three hours after sunrise and three hours before sunset. Experiments have shown that at sunrise a temperature lapse-rate of the order of 1° C. to 2° C. per metre often exists, the air being colder near the ground than higher up. In two or three hours this lapse-rate has disappeared, and a little later becomes reversed, so that with hotter air near the ground setting up convection currents, unsteadiness of the staff-image sets in, preventing further work. In the afternoon the ground cools very slowly, so that the change in the temperature lapse-rate, and consequently in the refraction, is then very gradual.

The error is, therefore, traced to the very rapid change in refraction during the early morning hours, of which the effect is noticeable in observations taken at a few minutes' interval. To eliminate it, all staff readings are now taken with as little delay as possible, and the observer reads alternately the backstaff first and the forestaff first—a procedure which has very materially reduced the systematic error, not only in precise levelling, but to a much greater degree in second-order levelling, where the time taken between successive readings is much longer.

[1] "Systematic Error in Spirit Levelling." By J. H. Cole. Survey of Egypt Departmental Paper No. 35. (Cairo, 1919.)

It has been recognised for some time that a systematic error may be caused by such a temperature inversion when levelling over sloping ground, but in the present report the rapid change of the temperature lapse-rate from a maximum value to zero is indicated as a cause which may be expected to operate even on level ground in any region where hot days follow clear, cold nights with effective radiation. In the last annual report of the Ordnance Survey such a systematic error, almost invariably of one sign, is referred to as being still unexplained. It would seem that here also local temperature inversions near the ground may be concerned to some extent.

H. G. L.

University and Educational Intelligence.

BIRMINGHAM.—Sir John Cadman is resigning his post as professor of mining at the end of the current session.

CAMBRIDGE.—On May 19 the degree of Doctor of Law *honoris causa* was conferred upon Lord Plymouth, Admiral of the Fleet Lord Jellicoe, Field-Marshal Lord Haig, Rear-Admiral Sir W. R. Hall, M.P., the Abbé Henri Breuil, Institute of Human Palæontology, Paris, and Sir John Sandys, Orator Emeritus.

LEEDS.—At a meeting of the University Council held on May 19, it was resolved that a chair of physical chemistry should be instituted, and Dr. H. M. Dawson was selected to be the first occupant of the chair. Since 1905 Dr. Dawson has been lecturer in physical chemistry at the University, and has carried out extensive researches in various branches of physical chemistry—in particular, investigations bearing on the constitution of solutions and on the mechanism of chemical change.

LONDON.—The degree of D.Sc. (Engineering) has been conferred on Mr. B. C. Laws, an external student, for a thesis entitled "Elasticity and Distribution of Stress in Thin Steel Plates," and other papers.

From the report of the Principal Officer (Sir Cooper Perry) for 1919–20, it appears that the University can look forward to a period of unprecedented development. Admissions by all channels in 1919–20 amounted to 12,608, almost double the corresponding number for 1913–14. Candidates for first degrees were 936, comparing with 1636, reflecting the diminished numbers of those who matriculated "during the lean—the honourably lean—years of the war." It is of interest to note that of the 1086 candidates for all degrees, 613 were internal and 473 external. This is gratifying evidence that the "private" student is tending to disappear, or, rather, to study under more favourable conditions. The list of benefactions to the University and its colleges is most encouraging. The outstanding gift is from the trustees of the Sir Ernest Cassel Educational Trust of 150,000*l.*, and 4000*l.* a year for five years. New University chairs have been established in aeronautics, modern Greek, Portuguese, Imperial history, Dutch, bacteriology, physiology, pathology, and physics. The question of hostel accommodation is being considered by a special committee. The report concludes on "a justified note of congratulation." The duty of the universities is plain; their province, though extensive and varied, is defined; their way is illuminated; "into the universities the nation looks in a unique degree for hearts and minds fitted to enrich the blood of the race—for the constant supply of men and women of trained insight and enlarged sympathies, apt for the higher offices of citizenship. This is our peculiar duty—to

conduct the Lampadephoria of the inspiration of humanity, and to guard and develop the most precious and enduring aspects of the most comprehensive of all the arts—the art of Life itself."

The new building of the Department of Applied Statistics and Eugenics (including the Galton and Biometric Laboratories) at University College, London, will be opened by Dr. Addison, Minister of Health, on Friday, June 4. The Vice-Chancellor of the University will preside.

Two lectures on Factors in the Froth-flotation of Minerals will be given at the Sir John Cass Technical Institute, Aldgate, E.C. 3, by Mr. H. Livingstone Sulman, on Wednesdays, June 2 and 9, at 5.30 p.m. The chair at the opening lecture will be taken by Mr. F. Merricks, president of the Institution of Mining and Metallurgy.

The Glasgow Technical College is preparing for its entrance hall a monument in bronze and marble to the 612 students and members of its staff who gave their lives in the war. To show the quality and quantity of the war work of the 3218 members, students, and past students of the college who served in the Army or Navy, or on special national duty, the college has issued, in a volume of 211 pages, a list of their names and services. The preface, by Sir George Beilby and Mr. Stockdale, the director, summarises the contributions of the college to research on fuels and explosives, the testing of war materials, and the training of munition workers. The normal classes had to be maintained for the thousands of evening students as well as for the many foreigners and refugees, for whom most of the day classes had to be continued in spite of the reduction in the staff. The successes enumerated include three awards of the Victoria Cross and 336 orders and crosses. Amongst the ranks attained, one student became colonel, fifteen were lieutenant-colonels, and seventy-seven majors. The letters quoted from the Government Departments express high appreciation of the research work conducted at the college. Of its contributions, both of men and mind, to the national strength, the college and science may well be proud.

The recently issued report on the war work of the College of Technology, Manchester (faculty of technology in Manchester University), gives an interesting account of the services rendered by members of the college in his Majesty's Forces—particularly in connection with the Royal Engineers and the technical branches of the Royal Navy—and in the many fields of scientific research opened up by the war. The greater part of the report is concerned with college war work other than that of supplying men. It appears that before the war was over the college was by no means large enough to undertake all the work which the military authorities—including the Air Board as well as the Admiralty and the War Office—were anxious to entrust to it. The mechanical and electrical engineering departments of the college were intimately concerned with the work of the Lancashire Anti-Submarine Committee, which had its headquarters in the college, and produced and developed several instruments, including, in particular, a deep-sea hydrophone for detecting and combating enemy submarines. The same departments helped to solve certain problems relating to the fitting of wireless apparatus to aeroplanes; for instance, a high frequency alternator, designed and manufactured in the college, was largely adopted for both naval and military 'planes. A new type of gas furnace designed in the college led to important improvements in the heat treatment of machine tools, involving an increase of 30 per cent. in the speed of the machining of shells and other munitions. The same research enabled the college to supply the Admiralty with special blades for cutting mine mooring cables, and when the demand for these blades was greater than the college could supply, the Admiralty required its manufacturers to employ the method of heat treatment devised in the College of Technology. An improved cast iron of high tensile strength, produced under the direction of the metallurgical department of the college, was usefully employed in the manufacture of gas shells. The college departments of applied chemistry and textiles carried out a number of investigations upon fabrics used in aircraft manufacture. A thorough investigation of the structure and scouring of airship fabrics led to the development of a process which was afterwards applied to all R.N.A.S. fabrics. The giant airships R33 and R34 were treated with a special dope produced at the college before starting on their long-distance flights. The chemical laboratories were also engaged during the war in investigating processes for the manufacture of explosives, pharmaceutical products, dyestuffs, rubber derivatives, and foodstuffs.

Societies and Academies.

London.

Royal Society, May 13.—Sir J. J. Thomson, president, in the chair.—Dr. A. D. **Waller**: Demonstration of the apparent "growth" of plants (and of inanimate materials) and of their apparent "contractility." In Sir J. C. Bose's original demonstration an amputated leaf was fixed up in connection with a crescograph, at a magnification stated to be $\times 10^7$, and the indicator was shown to be moving in a direction and at a speed that were stated as representing the growth of the petiole. Alternating currents were now sent through the leaf, causing a sudden reversal of the movement of the indicator, *e.g.* in the demonstration that the present author witnessed at the Royal Society of Medicine the indicator (a spot of reflected light) moved to the right at what he judged to be something like 1 metre per sec. in the direction of elongation (by growth?), and flew off scale in the opposite direction, at least ten times as fast, as soon as the buzz of the exciting coil was heard ("degrowth"). The demonstration was, in Dr. Waller's opinion, illusory. The movement to the right (indicating an elongation of petiole=0·1 m. per sec.) was indeed consistent with "growth," although its rate was surprisingly high under the conditions of experiment. The elongation might, however, have been due to, or modified by, many accidental variations of conditions—heat, moisture, handling of plant during preparation, etc.—and was precisely similar to the gradual elongation that takes place in a damp fiddle-string under similar conditions. The second part of the experiment, when the "excited" plant shortened and caused the indicator to fly off to the left, is held to afford conclusive proof of fallacy. The fact belonged to the familiar phenomena of heat contraction aroused by electrical currents in all kinds of (doubly refracting) moist conductors, whether living or dead, to the study of which attention was directed by Engelmann in his Croonian Lecture of 1895. These are demonstrable with a low-power crescograph ($\times 10^3$), and play a part in masking or simulating physiological changes when a high power ($\times 10^7$) is employed.—W. N. F. **Woodland**: The "renal portal" system (renal venous meshwork) and kidney excretion in vertebrata. The first three parts of this memoir contain, in the first place, proof that the assumption, commonly made in physiological literature, that the venous blood "supplied" to the kidneys of lower vertebrata mixes with

the arterial blood and traverses the system of channels known in mammals as the intertubular plexus, is erroneous—the renal afferent vein-blood does not supply the kidney tubules. The renal artery-blood traverses the intertubular plexus proper, and the renal afferent vein-blood a system of wide sinusoids (renal venous meshwork), which has no connection with the intertubular plexus, save that the latter opens into the former where the venous blood flows into the renal efferent veins. In the second place, much experimental and other evidence is provided to prove that the "renal portal" system is devoid of function so far as kidney secretion is concerned. Evidence is also adduced to show that the urine is solely secreted by the renal tubules, the glomeruli taking no part. The glomeruli (as will be explained in the forthcoming Part iv.) are solely to be regarded as retia mirabilia and function as such. This is the tubule-cum-rete theory of kidney secretion.

Zoological Society, May 11.—Prof. J. P. Hill, vice-president, in the chair.—Dr. W. J. **Dakin**: Fauna of Western Australia. III. Further contributions to the study of the Onychophora.—C. **Forster-Cooper**: Chalicotheroidea from Baluchistan.

PARIS.

Academy of Sciences, May 3.—M. Henri Deslandres in the chair.—C. **Moureu** and J. C. **Bongrand**: New researches on carbon sub-nitride. The action of the halogens, haloid acids, and alcohols. Numerous attempts to prepare the compound $CN—C\equiv C—CN$ in quantity proved unsuccessful, and hence experiments on this substance had to be confined to those requiring little material. The sub-nitride combines with bromine. Hydrobromic acid gives bromobutene dinitrile, $CN—CH=CBr—CN$, and hydriodic acid furnishes the corresponding iodine compound. Hydrochloric acid acts differently, addition and partial hydrolysis taking place simultaneously, giving chlorobutene nitrile amide,

$$CN—CH=CCl—CONH_2.$$

Ethyl alcohol forms an addition product, probably ethoxybutene-dinitrile.—J. **Constantin**: The fossil chalk Siphoneæ of Munier-Chalmas.—A. **Blondel**: Best conditions to be fulfilled by long-distance electric cables for energy transmission. Practical solutions.—A. de **Gramont**: The spectrographic detection of metals, especially zinc, in animal organisms. Details of the application of the spectrograph to the detection of zinc in the ash from snake poison.—G. **Julia**: Families of functions of several variables.—B. **Jekhowsky**: Differential equations of the second order verified by Bessel's functions of several variables.—J. Kampé de **Fériet**: The use of generalised differentials for the formation and integration of certain linear differential equations.—MM. **Descolas** and **Prétet**: The macrographic study of the propagation of cooling in the interior of a steel ingot starting from its solidification. The method is based on the appearance of the specimen after etching with dilute sulphuric acid (17 in 5).—D. **Hondros**: The integration of the Laplace equation between two non-concentric spheres.—M. de **Broglie**: The properties of reinforcing screens with respect to X-ray spectra and on a splitting of the β line of the K spectrum of tungsten.—G. **Chaudron**: Reversible reactions of water on tungsten and the oxides of tungsten. The constant $K=\frac{p(H_2O)}{pH_2}$ has been studied at temperatures between 600° C. and 1000° C. The results are given in both numerical and graphical forms.—C. **Zenghelis** and B. **Papaconstantinou**: Colloidal rhodium. Sodium rhodiochloride was reduced in presence of sodium protalbinate by various reducing agents, hydrazine sulphate, hydrogen gas, and formaldehyde, the last of which gave the best preparation. After dialysis and drying in a vacuum, brilliant scales are obtained which are very stable. Solutions have remained unchanged for two years. The crystals contain 33 per cent. of rhodium. Colloidal rhodium absorbs about 2700 times its volume of hydrogen, and from 300 to 1800 times its volume of carbon monoxide, according to the conditions.—O. **Bailly**: The action of neutral methyl and ethyl sulphates on alkaline phosphates in aqueous solution.—J. B. **Senderens** and J. **Aboulenc**: The catalytic decomposition of the fatty acids by carbon. The vapours of the fatty acids, from acetic to isovaleric, give no gas at 460° C. in the absence of a catalyst; but in presence of purified animal charcoal decomposition takes place at 360° to 380° C. The products of the reaction include carbon monoxide and dioxide, unsaturated hydrocarbons, hydrogen and methane, a liquid containing water, and traces of ketones and aldehydes. Sugar carbon is less active as a catalyst, and a much higher temperature is required to effect the decomposition.—P. **Guérin** and A. **Goris**: A new plant containing coumarin, *Melettis melissophyllum*. The presence of coumarin in this labiate has been proved: it probably occurs as a glucoside hydrolysable by emulsin.—Ad. Davy de **Virville**: Note on the comparative geographical distribution of *Primula officinalis, P. grandiflora,* and *P. elatior* in the west of France. *P. grandiflora* grows best in damp, shady spots, whilst *P. officinalis* prefers dry soil and positions exposed to sun; hence, although hybrids of these two species are readily formed, they rarely occur in Nature. In railway cuttings the conditions favourable to each species may occur in close proximity, and hence the hybrid is particularly abundant along railway lines. It is suggested that *P. elatior* may have originated as a hybrid between the two species above-mentioned.—H. **Coupin**: Seedlings which turn green in the dark. The green colouring matter of pine seedlings grown in the absence of light is not identical with that of pine seedlings grown in daylight. The differences are marked in *Pinus sylvestris*, less marked in *P. pinea*, and slight in *P. maritima*.—A. **Mayer**: The mode of action of the poison gases utilised during the war.—J. **Nageotte**: Formation and structure of blood-clots.—H. **Violle**: Milk and hæmolysis. Normal milk does not produce hæmolysis of red blood corpuscles, not even when mixed with 30 per cent. of its volume of water. Any milk producing hæmolysis after this addition of water is abnormal.—M. **Marage**: The limits of debility and pretuberculosis.—P. **Wintrebert**: Medullary conduction in *Scyllorhinus canicula*, and the supposed function of the transitory dorsal giant cells of Rohon-Beard.—M. **Lécaillon**: Eggs intermediate between the summer and winter eggs produced in the cocoon of the silkworm.—L. **Hudelo**, A. **Sartory**, and H. **Montlour**: Eczematoid epidemiomycosis due to a parasite of the genus Endomyces.—F. **Diénert**, F. **Wandenbulke**, and Mlle. M. **Launey**: The action of activated sludges.

Present State of the Dye Industry.

ON the occasion of the annual general meeting of the British Dyestuffs Corporation held on May 21 Sir Henry Birchenough, who has succeeded Lord Moulton as chairman of the company, emphasised the importance of a great dye-making industry as an instrument of national defence, pointing out that practically the whole of the poison gases used by the German Army in the war were made in the establishments of the German dye manufacturers, as well as large quantities of high explosives and synthetic nitric acid. Chemical warfare, in any future conflict, will no doubt be greatly extended, and its successful prosecution will depend on the equipment, skill, and experience of the dyestuff industry.

Scarcely less important is it in peace, for, as the chairman explained, "the group of textile trades of this country constitute the most striking and important single group of allied industries in the civilised world," and "the magnitude and very existence of a very large part of our export trade in textiles depend absolutely upon there being . . . a sufficient supply of dyestuffs available."

What is being done to establish a great dyestuff industry in this country? There is no doubt that progress has been very considerable, and it is a remarkable fact that the output of dyes in this country (given by the Board of Trade as 25,000 tons annually) exceeds the total consumption before the war.

The range and variety of these dyes are, however, admittedly limited, and, indeed, Mr. A. Hoegger, chairman of the British Cotton and Wool Dyers' Association, at the annual meeting held on the same day as the above, stated that, had it not been for the importation of certain Swiss dyes during the war, and the arrival recently of certain "reparation" colours from Germany, some of the branches of the association would have been seriously embarrassed.

There are two rather important points that require comment here. Sir Henry Birchenough stated that "an unprecedented demand for finished dyestuffs prevents the creation of stocks, and thereby places difficulties in the way of the maintenance of uniformity in our products." This is no doubt a reply to complaints as to lack of uniformity in the dyes supplied. There are two ways in which this can occur, viz. as regards shade and as regards strength.

If the preparation of a dye has been properly worked out in the laboratory and in the small-scale plant (such as exists at Huddersfield), the large-scale manufacture should present few difficulties. Granted that the first few batches may leave something to be desired, succeeding batches made under careful scientific control should certainly be very close to the standard required, and the stock necessary to allow this difference to be adjusted should not be more than three or four batches—say a ton at the utmost. With regard to the strength of the dye sent out, Mr. Hoegger states that a great proportion of the 25,000 tons is not so highly concentrated as were pre-war German colours. Almost every dye coming from the drying chamber is stronger than the standard, even taking as standard the German pre-war dye, and it is exceedingly bad policy to reduce the strength below it. This cannot be other than deliberate, and is very objectionable, as the quality of the dye is thereby depreciated in the mind of the user, and in this connection there is evidence that the Canadians are not altogether satisfied with the quality of the dyes imported from this country.

"Why," it will be asked, "cannot we make here those dyes which are being imported from Switzerland and vicariously obtained from Germany?" The answer to this question is: First, lack of plant; and secondly, lack of raw material. The former is referred to by Sir Henry Birchenough, who points out the great delay in delivery of plant owing largely to the moulders' strike. The provision of the multitudinous variety of pans, autoclaves, and acid-resisting vessels required by the industry is proceeding only slowly, and especially is this true of enamelled appliances. Even

the refuse of the engineering shops, iron borings, was no longer forthcoming during this strike, with the consequence that the manufacture of aniline was seriously retarded.

How the lack of special plant prevents the supply of certain dyes is well illustrated in the case of rhodamine. The intermediate products required for this are diethyl-*m*-aminophenol and phthalic anhydride. The former is prepared from diethylaniline, for which, unlike dimethylaniline, enamelled autoclaves are required, and the latter requires special plant for the oxidation of naphthalene by means of a mercury catalyst. Although indigotin is no longer prepared by the Badische process from phthalic anhydride, the importance of this intermediate is still great, and as the English rights of the new process of the American Bureau of Chemistry, oxidation in the vapour phase in the presence of a catalyst, have already been purchased, it may be expected that this product will soon be manufactured here at a comparatively very low cost. It will readily be understood that, in view of the necessity of installing two special plants for the intermediates required, manufacturers both in England and in America have not succeeded in placing anything but insignificant amounts on the market.

With regard to the provision of other intermediate products there is still much to do, and at the present time the demands for such elementary materials as aniline and β-naphthol greatly exceed the supply. The latter is required for the manufacture of such important intermediates as γ acid and J acid, and when it is considered that β-naphthol was not made in England at the outbreak of war, it will be realised that it is necessarily a slow operation to produce these acids, involving as it does three distinct plants.

It must not, however, be concluded that British manufacturers have confined themselves to the dyes which are made with least trouble. The Solway Dyes Co., in particular, was first in the field with a range of important vat dyes, and this firm, as well as the British Dyestuffs Corporation and others, has placed a useful series of fast dyes on the market. The erection of a large works in Trafford Park, Manchester, by the British Alizarine Co. must lead to a greatly increased output of alizarine dyes, and there is little doubt that slow but steady progress is being made. The time should not be far distant when British manufacturers will not only supply all requirements for the home market, but also make their products known all over the world.

Poetry and Medicine.

Philosophies. By Sir Ronald Ross. Pp. viii+5[illegible] (London: John Murray, 1911.) Price 2s. net.

Psychologies. 69 pp. (Same author and publisher, 1919.) Price 2*s.* 6*d.* net.

THESE slender volumes, by Sir Ronald Ross, deserve to be read with sympathetic interest for more reasons than one—not least because they reflect the mind, and throw light on the spirit which has guided the work, of a man whose services to medical science are great indeed. In the long history of medicine and of poetry we can call to mind many a physician who has been also a poet. No great physician has ever likewise been that rare and wonderful thing, a great poet, for the toilsome life of the one is not to be combined with the fine freedom, the careless rapture of the other. But there is a certain excellence which, though it fall far short of supreme perfection, is still a very fine and splendid thing, and to such excellence I think Sir Ronald Ross has certainly attained.

The poet-physicians whose names first cross our minds are men attached by but a slender link, a titular claim, to the profession of medicine; nevertheless, the profession is proud to have had enrolled among its brotherhood Dr. Oliver Goldsmith and the great apothecary whom a foolish critic bade "go back to his gallipots." In Goldsmith's footsteps follows Crabbe, bringing us his "Village" and his "Parish Register," bidding us, in lines scarcely less finished and less memorable than Goldsmith's own, "Behold the Cot, where thrives th' industrious swain, Source of his pride, his pleasure and his gain . . ."; or, moving quickly to sadder themes, "When the sad tenant weeps from door to door, And begs a poor protection from the poor." A little shred of Keats' great mantle (and more perhaps of Shelley's) fell upon that fine poet, and not unlearned physician, Thomas Lovell Beddoes, the friend of Blumenbach and Schoenlien and Frey—Beddoes of "The Bride's Tragedy." "Death is more a jest than life; you see Contempt grows quickly from familiarity. I owe this wisdom to Anatomy"—so he wrote from Göttingen while he was a student of medicine there; and the same contemptuous familiarity lasted him to the end, when he used his physiological knowledge of a new and terrible drug—curare—to "creep into his worm-hole," to introduce him to that grim pageantry of Death which his verse had described with a fearful reality. "The power of the man," said Browning, "was incontestable and immense"; and in his happy hours he had written very lovely and most

musical things. The song about "How many times do I love thee, dear?" is not to be forgotten; nor do those who have read it ever forget his exquisite "Dream-pedlary"—"If there were dreams to sell, What would you buy?"

To another order of poets belongs a little cluster of seventeenth- and eighteenth-century physicians, Garth and Akenside and John Armstrong and Erasmus Darwin. They are of that quiet, humourless, didactic school for which we have lost our relish, and for which Dr. Johnson (apart from his bitter quarrel with the last, the Lichfield, physician) had all too kindly a word.

We no longer read Garth's "Dispensary," any more than we read his once celebrated Harveian oration, although the poem was "on the side of charity against the intrigues of interest, and of regular learning against licentious usurpation of medical authority." In other words, it was a pedantic account of a quarrel between the College of Physicians and the Society of Apothecaries. "It appears," says Johnson, "to want something of poetical ardour, and something of general delectation"—a fair and honest verdict, which we might illustrate and support by any stray line or two—by those, for instance, where the poet describes "Why bilious juice a golden light puts on, And floods of chyle in silver currents run; How the dim speck of entity began T' expand its recent form and stretch to Man."

Akenside was a much better poet, and seems also to have been a more learned physician. His "Discourse on the Dysentery" "entitled him to the same height of place among the scholars as he possessed before among the wits"; and "The Pleasures of the Imagination" is still worth our while to read, if it be only for some few noble and exalted passages. We may lay it down, as Pope did, with the feeling that "this is no every-day writer!" There runs through it a sincere and almost prophetic belief in the value of research and the progress of science—in "Science herself . . . the substitute Of God's own wisdom in this toilsome world, The Providence of Man." Of Armstrong, who contributed some "medical stanzas" to "The Castle of Indolence," and wrote his "Art of Pursuing Health" in indolent Thomsonian verse, we need scarcely speak. He was admired in an age by no means devoid of polished culture, but content to read and even eager to buy such dreary, sluggish blank verse as "Hail sacred flood, May still thy hospitable swains be blessed In rural innocence," and so on, to the end of the quarto volume.

Erasmus Darwin's "Botanic Garden" and "Loves of the Plants" have merits of their own, and an historic interest not to be gainsaid; but in his poetry there is a *je ne sais quoi qui manque*, though it was wont at one time to be spoken of in the same breath with Cowper's "Task," and even with "Paradise Lost." They are the most didactic of didactic poems. The good doctor revels in facts, in the communication of knowledge, or rather of information. The world is ransacked for objects of wonder and contemplation. As his biographer, Miss Anna Seward, tells us, "the operations of the weather-glass and air-pump are described with philosophic accuracy and poetic elegance." There is "a grand picture, though of somewhat forced introduction," of the crocodile bursting from its egg on the banks of the Nile. The embryo plant is introduced to us by "Lo! on each seed, within the tender rind, Life's golden threads in endless circles wind, etc." We turn the page and come to "where the humming-bird, in Chili's bowers, On fluttering pinions robs the pendent flowers; Seeks where fine pores their dulcet balms distil, And sucks the treasures with proboscis bill." The sinuous track of the serpent glides, with no apparent reluctance, into "So, with strong arm, immortal Brindley leads His long canals, and parts the velvet meads." Yet the simple mind of this old poet-physician, utterly destitute of humour or romance, had (as we all know) a vast deal of wisdom commingled with its simplicity.

In our own day, or within our immediate recollection, there have been many members of the medical profession who could put on their singing robes once in a way, and write creditable verse or sing still better convivial songs. There was a whole brotherhood of them in Edinburgh a generation ago, with such men as Douglas Maclagan and Andrew Wood and James Sidey and J. D. Gillespie and John Smith, who touched art with the humour, and now and then with the pathos, of their post-prandial lyrics. But we had better not pause over the "Nugæ Canoræ Medicæ," or "Mistura Curiosa," or "Alter Ejusdem"—certainly not over that triumphant outburst of "old Sidey's" hilarious conviviality, "The Cat's got the measles and it's deid, puir thing!" scarcely even over the soft lowland accent and the tender lilt of "The burnie that wins to the sea"—"Up near the scaur where the hoodie-craw bides, Up near the foot of the keelie-craig hie, Deep in the hidie-heugh, riv'd frae its sides, Rises the burnie that wins to the sea." In the same town of Edinburgh we had very lately the Cornishman, Ricardo Stephens, another poet-physician, writer of strange ballads and dreamer of rich, imaginative dreams. It was he who

wrote "The Piper of Hell"—"O have ye heard of Angus Blair, Who lived long since in black Auchmair?" and a more terrible and cruel ballad still—"Who hath not met Witch Margaret? Red gold her rippling hair. . . . Come up and you shall see her yet, Before she groweth still; Before her cloak of flame and smoke The winter air shall fill; For they must burn Witch Margaret Upon the Castle Hill."

Together with these Edinburgh worthies we may say a passing word of two Dublin physicians of the last generation, George Sigerson and John Todhunter. They were both of them fervid writers of Celtic poetry, and have a notable place in their country's undoubted literary renaissance. Irish patriotism inspired them both, in a way that we little understand—as when Todhunter cries out "O thou Swan among the nations, enchanted long, so long That the story of thy glory is a half-forgotten song." He was a powerful and influential singer, a true Irish Tyrtæus; for it was he who wrote "There's a spirit in the air, Says the Shan Van Vocht"; just as another learned brother-scholar and fellow of Trinity College, Dublin (not a physician, however), boldly sang: "Who fears to speak of '98?" and sang it to only too receptive ears.

But I have gone farther afield than I ever meant to go, and I have left myself all too little room to write of Sir Ronald Ross, the last of our poet-physicians. Most of his poetry was written in India, in Madras or Burma or the Andamans, while he was engrossed in the study of the pathology of malaria, and during earlier years when he began to think and dream over the eternal problems of the East. Sir Ronald's love and reverence for science, and his admiration for those who have shown and followed the way of discovery, are deeper because far more experienced than Akenside's: "Tho' we may never reach the peak, God gave this great commandment, Seek."

It is not the wealth and splendour of the East that touch his imagination; but, looking with the physician's charitable eyes, he broods over the decadence, the misery, the widespread sickness of its people: "The leprous beggars totter trembling past, The baser sultans sleep." A famine-stricken girl is suckling her three-year-old: "'I am too poor,' she said, 'To feed him otherwise,' and with a kiss Fell back and died." It is all a gloomy picture. But if its blackness be somewhat overdrawn (and I hope and think it is) its pessimism is inspired and redeemed by charity and pity, by resolution to understand, and by ambition to relieve. Sir Ronald's second volume, though tragic enough, is in a happier strain.

Only a few days ago, lecturing to my class of some eighty young men and women newly entered a week before upon their medical course, I tried to tell them what the Protozoa meant to our fathers, and what (thanks to Pasteur and Grassi and Manson and Bruce and Ross and many another) they have come to mean to us. In my student-days, an Amœba, a bell or slipper animalcule, a little ooze from the Atlantic, a few pretty radiolarian or foraminiferal shells, gave us our outline-concept of the Protozoa. To-day a new world is opened, in which we hear of tiny things with strange life-histories, of momentous chains of cause and consequence wherein rat and louse and gadfly and mosquito play their insidious part, bringing fever to the swamp and murrain to the plain; we are told at last of mysterious maladies explained, of epidemics held at bay, of territories and peoples emancipated from disease. And then, as an example of the spirit of the scientific physician, of aims conceived, of dreams come true, I ventured to read them a couple of Ronald Ross's early verses, written before he and his fellow-workers had brought their hopes to fruition:—

In this, O Nature, yield, I pray, to me.
 I pace and pace, and think and think, and take
The fever'd hands, and note down all I see,
 That some dim, distant light may haply break.

The painful faces ask, Can we not cure?
 We answer, No, not yet; we seek the laws.
O God, reveal thro' all this thing obscure
 The unseen, small, but million-murdering cause.

My students listened and went quietly away, and I could see by their faces that they had heard the words of the poet and the physician as though he were speaking straight to them.

D'Arcy W. Thompson.

Movements of Plants.

Transactions of the Bose Research Institute, Calcutta. Vol. ii., *Life Movements in Plants.* By Sir Jagadis Chunder Bose. Pp. v+xiv+253–597. (Calcutta: The Bose Research Institute, 1919.) Price 19s. 6d.

In this the second volume of the Transactions of the Bose Institute, Sir Jagadis Bose continues to pour out his almost overwhelming wealth of observations. The first chapter of the volume deals with a piece of apparatus to be used with

the "high magnification crescograph" which magnifies the rate of growth up to ten million times. As, even with much lower magnifications, the spot of light or point of the lever would soon move off the scale or recording surface, the author has devised a method of balance different from the optical method originally used. In this new method the plant-holder is connected with a series of gear-wheels driven by a falling weight and controlled by a fan governor. By this means the plant-holder can be made to fall at various rates, and thus the growth of the plant is compensated, and we have what is termed the "balanced crescograph." When the rate of growth is exactly balanced the record will show a horizontal line, and any increase or decrease in the rate will be indicated by a rise or fall in the curve. By this means it is claimed that a change in the rate of growth of only 1 part in 27,000 can be detected. The method is one of great delicacy, it is clear, but, in view of the fact that the control of the speed of movement is in part frictional resistance, and also of the effect of grit and of inequality in the cutting of the gear-wheels, one would have liked to see the inclusion of a record which would demonstrate that a speed of 0.5 μ per sec. was kept constant to 1 part in 25,000 for many hours.

The volume contains thirty chapters on various plant reactions which exhibit themselves either by movements or by electrical response. Of these perhaps the most striking is the interesting contribution which the author makes to the problem of the mechanism of geotropic response. In the statolith theory of geotropism one link in the chain of reactions which bring about geotropic curvature is the shifting, under the influence of gravity, of comparatively large starch grains in a tissue such as the endodermis of the stem. This theory is upheld by the author as a result of the exploration of the plant by means of his "electric probe." The probe consists of a fine glass tube (0.15 mm. diam.) with a still finer platinum wire fused into, and projecting just beyond, it. The probe can be pushed into the tissues of a stem, while the other end of the platinum wire is connected with one terminal of a galvanometer, the other terminal being connected with some other part of the plant, *e.g.* a leaf, which is always kept horizontal. The probe is first placed on the surface of the organ, and the deflection is observed when the stem is placed horizontal; the stem is then returned to the vertical position, the probe advanced a little into the tissues, the stem again placed horizontal and the deflection observed. It is found that as the probe penetrates the deflection rises to a maximum and then falls to a minimum at about the centre of the stem. *The point of the probe in the position of maximum deflection is found to lie in the endodermis.* If the probe is carried forward towards the other side of the stem, a new maximum is found when the point reaches the endodermal layer on the other side, *but the deflection is in the opposite direction.*

This observation does not, of course, prove that the endodermis is the geo-perceptive layer, but it provides circumstantial evidence in favour of that view, since it demonstrates that the endodermis is the only tissue exhibiting a marked electrical reaction to geotropic stimulus. In one case where the angle of the stem was gradually increased there was no deflection until a critical angle of about 33° was reached, but above this there was a marked electrical response. There appears to be some frictional resistance to the displacement of the starch grains, which is not overcome until the critical angle is passed. By comparing the electrical response (which can, of course, be observed without the use of the "probe") of organs placed at angles of 90° and 45°, respectively, with the vertical, evidence is obtained in support of the view that the geotropic response is proportional to the sine of the angle.

The marked effect of temperature on the degree of geotropic response, which leads to decided diurnal movements of many stems, is a thesis which is further elaborated in this volume, as is also the difference between "direct" and "indirect" stimulation. The volume is filled with numerous and often stimulating observations carried out with the author's well-known mastery of the technique of experimentation. One must be grateful for the new weapons which he has forged and for the new fields of work which he has opened up, but, like Sir J. C. Bose's previous volumes, the present one is often sadly lacking on the plant-physiological side. The work done is never properly related to that of previous investigators, the author confining himself to the quotation of text-books, which are often of no very recent date; in dealing with phototropism the work even of Blaauw is not mentioned. Again, Sir J. C. Bose seems so anxious to add to his collection of "plant-records" that he passes rapidly from observation to observation and from problem to problem, shedding on the way a beam of light into some of the dark places of plant physiology, but never satisfying us with a problem fully envisaged and worked out.

Applications of Electricity.

(1) *Telephonic Transmission: Theoretical and Applied.* By J. G. Hill. (Manuals of Telegraph and Telephone Engineering.) Pp. xvi+398. (London: Longmans, Green, and Co., 1920.) Price 21*s.* net.

(2) *The Principles of Electrical Engineering and their Application.* By G. Kapp. Vol. ii., *Application.* Pp. viii+388. (London: Edward Arnold, 1919.) Price 18*s.* net.

(1) THE applications of electricity in the telegraph and telephone services are now so numerous and so highly specialised that no one can claim to have an expert knowledge of every branch. It has been decided, therefore, to produce a series of handbooks which will cover the whole of the ground involved. The editor of the series is Sir William Slingo, late engineer-in-chief of the Post Office, and most of the authors are on the staff of the Engineering Department. Judging from the present volume and from the names of the authors preparing the other volumes of the series, we shall soon have a very complete and thorough account of English telegraphic and telephonic practice.

This book is written for experts engaged in the practical applications of telephony, and must be judged from this point of view. It is now ancient history how the early telephonists did their best to diminish the capacity and resistance of their lines with the object of securing good communication. In 1887 Oliver Heaviside pointed out that this rule was quite fallacious. The two qualities of the line which it is necessary to study are the attenuation of the signals and the velocity with which they are propagated. Heaviside stated this clearly and showed that his "distortionless" circuit gave the complete solution of the problem. In 1900 Prof. Pupin showed how a distortionless circuit might be secured very approximately by putting inductance coils at certain intervals in the line. When the distance between the coils is small there will be little reflection of the waves by them, and in this case the practical working will be satisfactory.

There are many engineers employed in telephone work who have great difficulty in following the advanced mathematical reasoning of Heaviside and Pupin, and yet they have to evaluate their complicated formulæ in everyday work. For their benefit the author introduces additional chapters describing the transmission of direct currents along a leaky line and getting the equivalent circuits. This should give those engineers confidence to attack the complete mathematical problem which is given in appendices.

The symbols and general arrangement of the formulæ are mostly those used by Kennelly and Fleming, whose work is much appreciated by the British Post Office. To the general man of science most of the book will appear to be endless variations of complicated formulæ, involving complex variables, deduced from comparatively simple differential equations. But a study of the book will show him how laborious it is to get numerical solutions, and how ingenious are some of the methods employed to get the constants of the line. The chapter on "the human voice in telephony" is illustrated by excellent oscillograms of the alternating currents produced by certain words. There is also a chapter on the thermionic valve as a telephonic relay which is of great interest. Very instructive characteristic curves of the valve are shown. A curve is also given which proves the enormous variation of magnification with input. The use of these telephonic relays is most promising, and great developments may shortly take place.

The book will be of great value to the telephonic engineers for whom it is written. We were much interested in the electrical constants of many of the cables used in practice which have been calculated by the author. They prove conclusively the great value of advanced mathematical theory in telegraphy and telephony.

(2) As a pioneer of the applications of electricity Prof. Kapp has had the pleasure of seeing many of his theorems become incorporated in the routine teaching of technical colleges and many of his methods widely adopted in everyday practice. The technical student, therefore, will find much that is familiar in this volume; but he will also find that the proofs given in many cases have been appreciably simplified. The author invariably keeps practical considerations in the foreground and rarely, if ever, digresses on points of abstruse theory. In discussing the running of machines he makes little endeavour to [illegible] the theory, but gives, in most [illegible] first approximate solution. The book, therefore, will be welcomed by the engineer and the student. The former will gain a clearer view of the principles on which his machines work, and the latter will find that many long mathematical solutions can be much shortened by elementary graphical methods.

In the earlier chapters direct-current machinery is described. The treatment of the critical speed of turbo-dynamos is very neat, and the results agree with experiment. Little space is given to losses which are relatively unimportant—bearing friction, for instance. The methods of coupling dynamos for parallel running are fully described.

A clear description of the Thury system of direct-current high-tension transmission is given. There seems to be little chance, however, of this system being adopted on a large scale in this country. Chap. v. describes the uses of a storage battery in connection with a dynamo. Brief descriptions of the various types of booster used in this connection are given, and will be helpful to the student.

In chap. vii. a brief reference is made to Fourier's theorem. The coefficients are obtained by drawing the graphs of curves the equations of which are of the form

$$y=f(x)\cos(2\pi nx/\lambda),$$

and then getting their area by the planimeter. Although theoretically correct, we think that the method would prove laborious in practice. We think also that the error for high harmonics would probably be large, as the planimeter reading gives the difference between many areas.

The author suggests that large choking coils should be constructed in the form of a toroid, the diameter of the circular cross-section of which equals $0.311D$, where D is the mean diameter of the toroid. This is Maxwell's solution for the most economical coil; and the author has found practically that the expression $9.35n^2D$ gives its inductance, where n is the number of turns. This is in good agreement with Maxwell's formula, $3\pi n^2D$—*i.e.* $9.43n^2D$. It has to be remembered, however, that Maxwell's formula is only a rough approximation. If we use Rayleigh's formula we get $9.69n^2D$ for the inductance. The 4 per cent difference between theory and experiment is probably due to the assumption that the current is uniform all over the cross-section of the toroid. If we use Rayleigh's formula it will be found that we get very appreciably different dimensions for the most economical choking coil.

The discussions of parallel running, transformers, converters, and induction and commutator motors are all instructive and suggestive. The last chapter, on phase advancers, is a strong and convincing plea for their more general adoption in practice. Considerable economies can be effected by their use.

A. RUSSELL

British Iron Ores.

The Iron Ores of Scotland. By M. Macgregor, Dr. G. W. Lee, and G. V. Wilson. With contributions by T. Robertson and J. S. Flett. (Memoirs of the Geological Survey, Scotland: Special Reports on the Mineral Resources of Great Britain; Vol. xi. Iron Ores (continued).) Pp. vii+240. (Edinburgh: H.M.S.O.; Southampton: Ordnance Survey Office.) Price 10s. net.

THE present volume forms a continuation of the important series of memoirs on the iron ores of Great Britain which the Geological Survey has been issuing for some time past. Unlike some of the previous ones, the subject here discussed affords little scope for original geological investigations, the principal deposits of iron ore being very well known and having often been described. As is, however, very truly remarked by Sir Aubrey Strahan, the information concerning them is scattered throughout a large number of publications, and it is a great advantage to the student of the subject to have it all brought together in one volume. The authors have done their work carefully and painstakingly, and the result of their labours has been to render available a very complete and minutely accurate record of the known Scottish iron ore deposits.

The book is divided into seven chapters. The first gives an introductory and historical account of the subject, containing much interesting matter; attention should, however, be directed to a mistake as to the nature of the old Catalan furnace. The author writes: "These furnaces were of the Catalan type, ... and castings were apparently made direct from the furnace itself." These two statements are incompatible, for the essential feature of the Catalan process was that it produced malleable iron, and not cast iron, direct from the ore.

The next four chapters are devoted to the bedded iron ores of Carboniferous age, these being subdivided mainly according to their geographical distribution. In a sixth chapter the bedded Raasay ironstone of Jurassic age is described, and in the last chapter a number of minor occurrences, which are grouped together under the heading "Hæmatite in Veins and Beds"—a somewhat infelicitous title, seeing that true hæmatite is conspicuous by its absence.

As in the previous volumes of the series, the least satisfactory portion of the present one is that relating to the estimated tonnage of ore reserves. It ought to be made thoroughly clear that the tonnage of ore as estimated by a geologist represents a quantity many times greater than that which the miner can hope to recover in actual practice. The iron industry of Scotland requires some $2\frac{1}{2}$ million tons of ore annually, about one-fifth of which is obtained from native Scottish deposits, and it is poor consolation to the Scottish ironmaster, who for a good many years past has

been in the greatest difficulty to know whence to draw his ore supplies, to be informed officially that the probable reserves are more than 94 million and the possible reserves more than 435 million tons, he meanwhile knowing but too well that only a very small fraction of even the smaller figure is ever likely to find its way to his furnaces.

Our Bookshelf.

Practical Pharmacology: For the Use of Students of Medicine. By Prof. W. E. Dixon. Pp. viii+88. (Cambridge: At the University Press, 1920.) Price 7s. 6d. net.

WE welcome the appearance of Prof. Dixon's manual; it is certainly the most practical and useful guide to students of experimental pharmacology which we know. The experiments are extremely well chosen to illustrate the underlying principles of therapeutics, and the text, with its illustrations and tables, is so clear and logical that a student can at no time be in doubt as to the methods for performing the experiments, or fail to appreciate their bearing on the practical application of the drugs in disease.

The experiments, some seventy-eight in number, are classified to explain the action of drugs on the various systems of the body, and while use is made mainly of the pithed frog, suitable experiments with mammalian tissues are introduced. Experiments with decerebrated mammals are not described, the author considering that their use in large classes is impracticable and that they may be replaced by suitable demonstrations under Certificate C. A chapter is devoted to a description of the essential physical properties of important drugs, and there is appended a useful table of the doses required to produce typical pharmacological effects in animals.

We have no hesitation in recommending this book as an excellent guide to the study of practical pharmacology. It is one which will be extremely useful to students of medicine, whether they are receiving experimental tuition in the laboratory or not, and it will also be read with much profit by medical men who have not had the advantages of a practical training in the action of drugs.

The Teaching of Science in the Elementary School. By Gilbert H. Trafton. (Riverside Text-books in Education.) Pp. x+293. (New York: Houghton Mifflin Co.; London: Constable and Co., Ltd., 1918.) Price 6s. 6d. net.

IN a brief introduction Prof. Cubberley states that the author's aim was "to construct a simple and helpful volume for the teacher who is called upon to teach elementary science lessons, and yet has neither scientific training nor apparatus for the work." The statement prepares the reader for the limitations of the book. Mr. Trafton's scheme includes practically no chemistry, and the physics is both exiguous and scrappy; by far the greatest part consists of simple observational work upon plants and animals. Within these limitations, however, there is much that is both attractive and useful, and the limitations themselves correspond to those of most rural elementary schools in this country.

Mr. Trafton classifies his subject-matter under the headings of biological, agricultural, physical, and hygienic science, and rightly insists that, however rudimentary the work along these lines may be, it should be done in the genuine scientific spirit. In his introductory chapters he gives a good deal of sound and practical advice with regard to the choice of subject-matter and the methods of teaching, and the bulk of the book consists of sections in which typical parts of the curriculum he recommends are worked out in detail. The curriculum is, of course, chosen with reference to American conditions, but the English teacher should be able to profit by Mr. Trafton's suggestions. There is a carefully compiled bibliography, covering practically the whole field treated in the book, but consisting entirely of American titles.

Peoples of the Philippines. By Prof. A. L. Kroeber. (American Museum of Natural History: Handbook Series No. 8.) Pp. 224. (New York: American Museum of Natural History, 1919.)

THE interest of the Philippine Islands to the ethnographer lies in the fact that they are the largest of the possessions of the United States, and the only one of importance in the Eastern hemisphere; that they form a considerable and growing nationality; and that they display in an unusually complete manner the stratification of races and cultures. Three types of race can be identified in the present population, and these may be arranged in the probable order of their arrival—the Negritos of the interior, a short, black people with an elementary type of religion and culture; the Indonesians, of the Mongoloid family, but presenting fewer specific Mongoloid features than the third race, the Malayans, occupying the coastal areas. As regards culture, the remarkable fact is the predominance of Indian influence as compared with that of China, which provided little more than certain manufactured products. India did not furnish the Filipinos with a definitely crystallised religious cult, or, if so, this cult had already disappeared before the Europeans appeared on the scene. But there came from the Indian races, probably by Malay intervention, a mass of religious practices, ideas, and names, a considerable body of Sanskrit words, a system of writing, the art of metallurgy, a vast amount of mechanical and industrial knowledge, and unquestionably a much higher degree of civilisation than their predecessors had acquired. These facts are clearly brought out in the present handbook, which provides in small space much information, and is furnished with good maps and illustrations.

Letters to the Editor.

The Flight of Flying-fish.

IT is disputed whether the flight of flying-fish is a genuine flight or simply a leap and a glide. The question is referred to in the section devoted to flying-fish in the Natural History Museum, South Kensington. Recently I have had ample opportunity to study these fish in the tropical waters of the Atlantic and Pacific Oceans.

The observations which I have made and the conclusions at which I have arrived are corroborated by the officers of the R.M.S. *Victoria*. Many of these gentlemen were surprised to hear that there was any doubt on the matter. That the flight is a genuine one is proved by the following facts:—

(1) During flight these fish are able to turn at right angles, and even at a very acute angle. More than once I have seen a fish turn with great rapidity at an acute angle and come back in a direction opposite to the direction in which it set out. A mere glide will not enable any animal to do this.

(2) Standing at the bow of the ship directly above some flying-fish which were in a hurry to get out of the way, I saw the wings flap as distinctly as the wings of any frightened bird.

(3) Some of these fish fly for a distance of from 150 to 200 yards without rising more than a couple of feet above the surface. They rise over the crests of the waves and sink into the hollows. They could not do this by a mere leap and a glide.

(4) Besides flying low over the surface of the waters, they are also able to rise to a considerable height, and not infrequently come on board large steamers. When they fall on deck their wings can be seen, as well as heard, flapping. It is true that they are unable to rise from the deck, but the same is true of many sea-birds.

(5) When in full flight the outlines of the wings are indistinct and blurred in contrast with the clear outline of the body. This can only be due to the very rapid movement, as in the case of hovering flies and humming-birds.

J. McNAMARA.

3 Holland Road, Kensington, W.

An Experiment on the Spectrum.

IN school and college courses little experimental work is done on the infra-red and ultra-violet parts of the spectrum. The student is, of course, told about these regions, and how they can be detected respectively by the heating and actinic properties of their rays. But he is not allowed to investigate these rays himself, nor are their properties demonstrated before him. This is on account of the elaborate nature of the apparatus necessary; the infra-red region requires a thermopile or bolometer, together with an expensive galvanometer, and the ultra-violet requires photographic methods and a spectrograph. So much apparatus cannot be afforded for one experiment, and besides is apt to distract the student's attention from the simple nature of the facts involved.

If, however, a very intense spectrum is used, the infra-red can be mapped roughly with an ordinary thermometer, and the ultra-violet with a photographic exposure-meter. Neither galvanometer nor spectrograph is necessary. The thermometer I have used is a Fahrenheit one, range 0° to 220°, the bulb of which is blackened by dipping it into lamp-black shaken up with methylated spirits; the bulb is 5 mm. in diameter. The exposure-meter is the Imperial exposure-meter for dull light and interiors, which costs 1s. 6d. together with a refill. In this instrument a piece of sensitive paper is exposed to the light, and the time noted that it takes to darken to a standard tint. The sensitive paper supplied darkens two or three times as fast as ordinary P.O.P. As source of light I have used a little 5-ampere arc lamp, which is run off the lighting circuit through a rheostat. The anode is horizontal and the cathode vertical; they are both enclosed in a glass cylinder which restricts the supply of oxygen, and so lengthens the life of the carbons. Lamps of this pattern burn very steadily, and have come into wide use during the past ten years. It is because so many laboratories have these lamps that I describe this experiment here. An arc of this pattern is absolutely necessary; a pointolite or half-watt lamp is of no use for the purpose.

As lens I have used a spectacle lens of 25 cm. focal length, and as prism a single equilateral dense flint $1\frac{1}{4}$ in. high. The spectrum and arc are equidistant from the lens. As slit I have used the crater of the arc, which measures about 3 mm. in diameter, since the carbons in this type of lamp are only 5 mm. thick. If the rays of light from the anode fell squarely on the lens we should have a point image of a point source, and the spectrum would be only 3 mm. high, but by setting the lens obliquely, rotating it through 30°, an astigmatic line image is formed, and we get a reasonably sharp spectrum 12 mm. high. Stray light is excluded by enclosing the arc in a box.

The following table gives a set of results taken in somewhat less than an hour:

Scale cm.	Colour	Rise of temperature °F.	Photographic action
7·0	—	0·0	—
7·5	—	0·8	—
8·0	—	3·4	—
8·5		5·4	—
9·0	Infra red	3·4	—
9·5	Red	2·0	—
10·0	Yellow	0·5	0·5
10·5	Green	—	2·7
11·0	Blue	—	1·5
11·5	Violet	—	2·4
12·0	End of visible	—	5·0
12·5	Ultra violet	—	5·0
13·0	—	—	0·57

The ends of the visible spectrum were at 9·2 and 12 cm. The first column gives the readings on a centimetre scale placed along the spectrum, the second column the name of the colour, the third the rise of temperature experienced by the thermometer in three minutes, and the fourth the reciprocal of the time in minutes taken by the paper to darken to the standard tint. In the case of the last two readings the exposure-meter was illuminated by stray light. It is possible to go further into the ultra-violet if a crown glass prism is used. The infra-red measured goes to $2 \cdot 2\,\mu$ or thereabouts. If a piece of P.O.P. is exposed to the spectrum for a couple of minutes, it shows bands—one from 10–11 cm., another from 11·3–11·7 cm., and a third from 11·8–12·7 cm., the positions all being measured on the centimetre scale above referred to.

It is interesting to remember that when Sir William Herschel discovered the heat spectrum in 1800 he used thermometers. The source of light was the sun, and the arrangement was similar to Newton's original one—the prism was placed close up to a slit at a window, no lenses were used, and the spectrum

was consequently very impure. Three thermometers were placed apparently at a distance of about 4 ft. or 5 ft. from the prism—one in the spectrum, and the other two in the shadow beside it—and the difference of temperature produced by the rays was noted. The bulbs of the thermometers were blackened; one of them measured $\frac{1}{2}$ in. in diameter, but the others were smaller. One and a half inches beyond the red there was a rise of $3\frac{1}{2}°$ in 10 min., 1 in. beyond the red $5\frac{1}{2}°$ in 13 min., and $\frac{1}{2}$ in. beyond the red $6\frac{1}{2}°$ in 10 min. In the violet there was a rise of 1° in 15 min. The spectrum was about 3 in. long, and the heat rays could be detected a distance of $2\frac{1}{2}$ in. into the infra-red.

University of Glasgow, May 19

Anti-Gas Fans.

IN a note in NATURE for May 13 you intimated that my "allegations" concerning the treatment of my anti-gas fans by the War Office and the suffering and loss of life thereby entailed could not be accepted without question, and you called upon the "well-accredited men of science," who, you say, largely staffed the Anti-Gas Service, to make a 'plain statement of the facts." I waited to see if such a statement would be forthcoming, though I judged it scarcely likely; and now, since it has not appeared, I ask you, in fairness, to grant me space for a few remarks on your note.

You suggest that such an indictment as I have brought against the War Office, reinforced as it is with their own letters, reports, and pamphlets, can be refuted by the bare word of certain "well-accredited men of science." I pass over the implied slur on myself of being less well-accredited than they, my word of smaller value than theirs No unprejudiced person who has read that indictment and that evidence with any care will agree with you that they can be thus easily disposed of.

In my dealings with the War Office I had to do with innumerable officials, some of them men of science, most not. From their behaviour I judged the larger number (and the exceptions were not, I regret to say, men of science) to be mere puppets, acting under the direction of some leading spirits behind. Who those leading spirits were I had no means of knowing; I was carefully kept in the dark. You, sir, intimate that they were "well-accredited men of science." If this was indeed so, then surely you will agree with me that, for the sake of science even more than in the interests of the nation at large, it is essential that this matter should not be hushed up, but that a public inquiry should be instituted I am not only willing, but also most anxious to submit my case to some impartial tribunal Will the men of science whom you have asked to speak, but who do not answer, come out into the open and join with me in demanding such an inquiry? If not, both the world of science and the general public will know what to think.

HERTHA AYRTON.

41 Norfolk Square, Hyde Park, W., May 23.

[WE did not express an opinion upon the charges made by Mrs. Ayrton, but limited ourselves to a statement of the indictment, and pointed out that it was really directed against the men of science associated with the Gas Service of the Army. Possibly these officers are not free to enter into a discussion of reasons for the neglect of the use of the fans, and nothing short of a public inquiry will elicit the whole of the facts in regard to them.—ED. NATURE.]

A New Method for Approximate Evaluation of Definite Integrals between Finite Limits.

THE subject has a particular interest for naval architects, inasmuch as the majority of calculations relative to displacement, stability, strength, etc., of ships involve the finding of areas and volumes bounded by curved lines and surfaces.

The particular rule enunciated by Mr. A. F. Dufton in NATURE of May 20 has been in use at this college for some years, and gives very accurate results in obtaining areas and volumes, and also, by a further application, the positions of their centres of gravity.

The method of its derivation was from one of Tchebycheff's rules. $f(x)$ in this particular case is taken as $(a+bx+cx^2+dx^3+ex^4)$. It can readily be shown that the value of

$$\int_0^1 f(x)dx = \tfrac{1}{4}[f(x_1)+f(x_2)+f(x_3)+f(x_4)],$$

where

$$\Sigma x_1 = 2, \quad \Sigma x_1^2 = \tfrac{4}{3}, \quad \Sigma x_1^3 = 1, \quad \Sigma x_1^4 = [illegible],$$

whence $x_1 = 0.1027$, $x_2 = 0.4062$, $x_3 = 0.5938$, and $x_4 = 0.8973$. The approximation "to one-tenth, four-tenths, six-tenths, and nine-tenths was obvious, and all the more welcome because it is our usual practice to divide the ship's half-length into ten sections. No special sections have to be drawn, calculations being readily made with the aid of the existing drawings.

This rule was briefly referred to by Mr. W. J. Luke at a meeting of the Institution of Naval Architects in 1915 (Trans. I.N.A., vol. lvii., p. 219).

The application of Simpson's ordinary rule to find the area of a quadrant or semicircle, as quoted, manifestly shows Simpson's rule at its worst, owing to the wide divergence of the curve from the assumed curve from which the rule is derived. Where curves approximate to these forms, as in many sections of a ship, it is common practice in the use of this rule to interpose intermediate ordinates where the curve is "steep"—relative to the base line—to get greater accuracy

An interesting paper dealing with this subject and giving a great variety of rules for approximate integration was read at the Institution of Naval Architects in 1908 (Trans. I.N.A., vol. l.) by Sir W. S. Abell entitled "Two Notes on Ship Calculations."

F. MERCHANT.

Royal Naval College, Greenwich, S.E., May 27.

Applied Science and Industrial Research.

YOUR correspondent Mr. J. W. Williamson says in NATURE of May 27 that much of my criticism of the Department of Scientific and Industrial Research "seems to lend colour" to current misconceptions of industrial research, which he proceeds to construct out of his own imagination, having first fathered them on me, and then submits that the cause of pure science is not well served by inconsiderate attacks on the industrial research movement, such as he would have it believed I made. I judge from this that he was not present at the meeting, and I therefore wish it to be known that the full text of my address to the National Union of Scientific Workers can be obtained by forwarding a stamped addressed foolscap cover to the General Secretary, 19 Tothill Street, Westminster, S.W.1. If Mr. Williamson will have the goodness to read it and the full report of the meeting published in the current issue of the *Scientific Worker*, the official organ of the union, and then say, if he still desires, what he objects to, it would help rather than confuse the issue.

FREDERICK SODDY.

MR. WILLIAMSON'S letter in NATURE of May 27, in which he criticises the attitude of Prof. Soddy and that of the National Union of Scientific Workers towards the Department of Scientific and Industrial Research and the struggling research associations, confuses the issue. To attack the Department or association entrusted with industrial research is tantamount neither to attacking industrial research nor to making invidious distinctions between pure and applied research.

In the minds of the members of this union there exists no belief in the superiority of pure science over industrial research; it has always been our expressed opinion that there is no difference in their scientific value. In one of our explanatory pamphlets this view is expressed: "It [the union] aims at including within a single scheme both academic and technical members . . . The separation of science and industry has been a principal cause of our disastrous neglect of science in the past, and if continued will remain harmful to both in future. The present organisation, by ensuring the intercourse of the two sides, is therefore desirable on both national and scientific grounds." Embodied in our rules we have as avowed objects: (1) To advance the interests of science, pure and applied, as an essential element in the national life. (2) To promote and encourage scientific research in all its branches.

Our criticism is that in any scheme put forward by the Department inadequate facilities are given to that type of research which, though it has less immediate application, is probably of greater ultimate importance through leading to the better understanding of more phenomena. It would be quite unfair to expect particular industrial research associations to contribute more than others to the prosecution of research which might have a common application to industry or to some aspect of the national life. Obviously this type of work is best carried out at the universities or at institutions such as the National Physical Laboratory. Yet how is this research fostered at the universities? According to the last report of the Department, sixty-eight research workers and their assistants and thirty-five students in training received allowances and grants for equipment amounting to 14,170*l.*; this is at the rate of 53*s.* a week, and includes equipment. Contrast this grant with the salary of 4000*l.* a year for the director of the Glass Research Association—an appointment which is an affront to all scientific workers. Millions have gone into State-protected industries to the accompaniment of an astounding appreciation in the value of the shares held by individuals in the State-aided industry. But the universities are begging for funds to provide decent bench accommodation and instructors for their science students. Speaking at Liverpool on May 28, Dr. Adami is reported to have said that if the university raised the salaries of its demonstrators to a proper standard it would lead to bankruptcy.

It is unfair to suggest that we are criticising the Department for the starvation of pure scientific research because industrial research is fostered; on the contrary, we are anxious for the advancement of both. We are of the opinion that neither branch of science is receiving adequate support, but that research carried out in the general interest is in the more unfavourable position. If we attack the Department it is because we honestly believe it is for the betterment of research—a maximum of efficiency in the administration of the funds available which must inevitably tend towards the better appreciation of science.

At the conference of research associations held under the auspices of the Department of Scientific and Industrial Research on May 14, I heard several representatives express opinions almost identical with those of the National Union of Scientific Workers; suggestions were made and questions asked which are provoked by Prof. Soddy's address. Mr. Williamson himself dealt with the economic position of the research workers, and made suggestions for improvement which might have been those of a member of the executive of this union.

We entirely concur with Sir Frank Heath that the Department of Scientific and Industrial Research is embarked on a great adventure. Mr. Williamson will agree that it is our concern to work for the safety, honour, and welfare of the adventurous scientific workers. So far we have heard too much of the rights of the financial interests concerned to work out their own salvation with money provided largely by the State, but very little of the rights of the scientific workers to safeguard their own interests. We wish to be assured that the leading spirit in the adventure is sufficiently well advised to guide him in his choice of officers for this army of truth-seekers, and that his army is not defeated by ignorance, mishandled by an unsympathetic staff, or starved to feed the parasites of science.

A. G. CHURCH,
Secretary.

National Union of Scientific Workers,
19 Tothill Street, Westminster, London, S.W.1, May 31.

The Great Red Spot on Jupiter.

WHEN this remarkable object came into striking prominence and attracted general observation in 1878, the rate of its rotation period was slightly increasing, and it continued to increase until the end of the century. Then in the early part of 1901 a large irregular spot appeared in the south tropical zone of Jupiter. This new feature, moving swifter than the red spot to the extent of about 23 seconds per rotation, soon affected the motion of the latter by accelerating its rate as it overtook it, and this influence has been repeated prior to the seven occasions on which the two objects have been in conjunction during the last twenty years.

The rate of rotation indicated by the red spot has, in fact, been a very variable feature in recent times, and the marking named has exhibited an increased velocity and a shortening period. In the years from 1894 to 1901 the mean period was 9h. 55m. 41·3s., but in the last eight years it has been 9h. 55m. 35·7s.

I have shown the annual differences in Fig. 1, and the rate of rotation determined each year I have also tabulated for inspection and comparison:

	h. m. s.		h. m. s.
1878	9 55 33·7	1899 ...	9 55 41·6
1879	34·1	1900 ...	41·4
1880	35·2	1901 ...	40·7
1881	36·3	1902 ...	39·6*
1882	37·3	1903 ...	40·2
1883 .	38·2	1904 ...	39·7*
1884 .	39·0	1905 ...	41·2
1885 .	39·6	1906 ..	39·5*
1886	39·9	1907 ..	40·9
1887	40·1	1908 ...	39·6*
1888	40·2	1909 ...	40·3
1889	40·4	1910 ...	37·4*
1890	40·5	1911 ...	37·4
1891 .	40·6	1912 ...	37·2
1892 ..	40·8	1913 ...	34·8*
1893 ...	40·9	1914 ...	35·5
1894 ...	41·0	1915 ...	37·5
1895 ...	41·1	1916 ...	36·4
1896 ...	41·3	1917 ...	34·5
1897 ...	41·5	1918 ...	33·7*
1898 ...	41·7	1919 ...	35·5

The values are smoothed up to 1900, but not in later years.

I have placed an asterisk in the table and diagram to those years in which a conjunction occurred between the red spot and the south tropical spot. In every case it will be seen that the red spot moved at a more rapid rate in those years when conjunctions were observed.

The south tropical spot or disturbance is a totally different object both in form and nature, and probably in origin, from the great red spot. The latter has preserved its symmetrical oval form since it was observed by Dawes in 1857, but the former has varied enormously in its length and detail. In 1901 it was scarcely more than 20° long, in 1902 July 87°, in 1903 48°, in 1905 44° to 60°, in 1911 115°, in 1912 65°, in 1913 March 140°, and in 1918 180°, so that in the last-mentioned year it extended half-way round the vast diameter of Jupiter.

This marking exhibited undue faintness in 1918 and the early part of 1919, and it appeared to be on the eve of disappearing, like the hollow in the great south equatorial belt where the red spot lies. However, there has recently been some intensification in the material forming the south tropical spot, so that observations are being made to trace its position and developments. It is satisfactory also to know that the red spot itself continues to retain its definite form, and is sufficiently distinct to be within easy recognition when a steady air conduces to good seeing. This spot seemed to be breaking up or wearing out early in 1919, but it has recovered something of its old-time aspect, and is well within reach of the telescopes usually in the hands of amateurs.

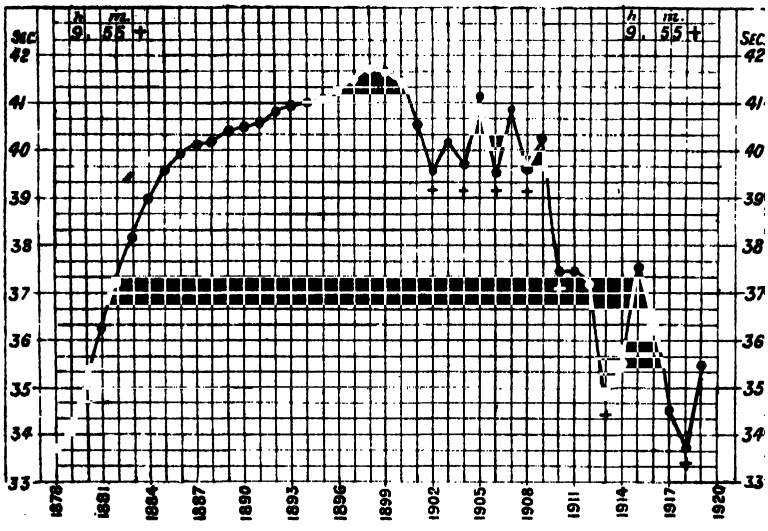

FIG. 1.—Rates of rotation of the Great Red Spot on Jupiter.

Since Schwabe first saw the hollow on the south side of the great south equatorial belt of Jupiter in 1831 September 5, the planet has rotated more than 78,000 times. There is every reason to conclude that the object he saw is the same as that which has been so prominently visible in recent years in close contiguity to the red spot. The two features appear to have participated in one and the same fluctuating rate of rotation, a mean of which was 9h. 55m. 36·8s. during the 88½ years included in the observations.

The observations upon which my deductions for recent years are based were made by the Rev. T. E. R. Phillips and Mr. F. Sargent, and I take this opportunity of acknowledging their kindness in furnishing the necessary materials. My abstention from planetary work has been practically enforced, but, amid the regret caused thereby, I feel great satisfaction in the fact that others are pursuing it with much ability and energy.

W. F. DENNING.

Bristol, May 11.

British and Foreign Scientific Apparatus.

Now that we are living in an age of "trusts" there is no need to fear foreign competition in respect to prices. The only points our home manufacturers should lay stress upon are quality and quantity, and should these be maintained at a high level they can hold their ground against foreign manufacturers; that is, so long as the manufacturers throughout the world have confidence in their respective associations. Whenever these commercial associations begin to fall asunder we may expect competition in prices to operate, and then it will mean a commercial war, not between nations, but between individual manufacturers in Europe and America. The result will mean financial benefit to the users of scientific apparatus, just as the recent slump in prices of the necessaries of life may soon prove to be advantageous to consumers generally throughout the world.

Scientific apparatus is as necessary to the maintenance of healthy life as are hygenic clothing and wholesome food; and if protection for British manufacturers is required in the form of prohibition except under licence to induce them to improve the quality and the output, with the ultimate object of developing an optical industry within the Empire of such importance that there would be less danger to the State in the event of another war, why should the users of scientific apparatus be expected to bear the hardships in regard to poorer quality and higher prices even for a temporary period? Surely it is a question for the Government to decide as to what amount of State aid is required to develop a key industry that the whole nation may be called upon to bear the expense instead of an extremely small minority of the population.

In pre-war days our principal foreign competitor was Germany, not so much in price as in quality, and if German manufacturers were able to develop an industry of very considerable importance without State aid, why cannot British manufacturers do likewise?

There was one person in Germany who was more responsible than all other makers together in lowering prices, viz. Leitz of Wetzlar. He always appeared satisfied with a comparatively small profit, and aimed at a very large output; and, I believe, he was the first to sell 1/12-in. oil immersion objectives at 5l., and curiously this ultimately became a uniform price throughout the trade in Europe and America. The same maker sold students' microscope stands at 55s., which, with suitable optical equipment, was a serviceable instrument with highest magnifications. The prices of these articles to-day are 9l. and 8l. 5s.—higher than the British equivalents.

Since the armistice German manufacturers have

been obliged to adjust their prices in accordance with the rate of exchange for each country to which they export, and for our country their prices are at present 100 per cent. on average above pre-war English prices. The wages in the German optical industry have increased more than 400 per cent., and are likely to rise still higher. Opticians and mechanics earning the equivalent of 1s. per hour before the war now receive 5s. 6d. and have a working week of forty-eight hours. They are living in a state of semi-starvation, passing through an experience at present much worse than anything we endured in the war, and unless foodstuffs are sent from England and America the Germans may be forced to conditions similar to those experienced by them during the last two years of war, until the next harvest provides better supplies. The low value of German money makes it exceedingly difficult for manufacturers to import raw materials. Many iron and steel works are closed for want of coal, and most of the coal delivered from the mines is what our miners call "dust." "The French take the coal and leave the rubbish, which is good enough for the Germans." Motor lorries are standing idle for want of petrol or benzol; and, for transport, horses are employed instead. Manufacturers do not pay a percentage on excess profits, but have to deliver up the whole of these profits to the State.

I fully appreciate the question which Mr. Baker raises in his letter appearing in NATURE of May 20: "The rate of exchange makes the prices seem low as compared with those in this country, but can Prof. Bayliss obtain delivery at the low prices?" Having spent six weeks recently in the German interior and purchased a considerable quantity of optical apparatus, I found it impossible to get the goods exported to England at the rate of exchange, but had to pay English prices in English money; also it was necessary to obtain licences from the German Government before goods could be exported.

The foregoing statements indicate briefly some of the conditions prevailing in the scientific apparatus trade in Germany, and there is evidence of their having to continue for a very considerable period.

I believe our manufacturers have had the opportunity of a lifetime since the armistice, and there is still time to reorganise British workshops to compete successfully with foreigners without State aid, but with courage, capital, and enterprise.

The proposed Anti-dumping Bill is a misnomer. There is no dumping done in scientific apparatus in our country, and never has been any. We could produce quality equal to or better than that of any other nation if we set ourselves to the task. One example during the war—the best aerial photographic lenses were made by an English firm. Germany came second. The tests were made by disinterested officials in the Royal Air Force.

J. W. OGILVY.

Hill View, Westerham Hill, Kent, May 25.

THE letters from manufacturers on the subject of the supply of scientific instruments are interesting and fairly unanimous, but appear to me to miss the whole point of the situation. That is, that after five years' freedom from competition our manufacturers cannot in many classes of scientific instruments compete successfully with German firms.

If the rate of exchange is the cause of the importation of German instruments, what is the cause of hundreds of American microscopes and lenses being sold during and after the war with the rate of exchange adverse to us? The Germans are selling their goods in England at *current English rates* and above, yet find a ready sale. At first, it is true, some individuals smuggled in German instruments at mark rates, but as soon as the extent of the demand was realised, German firms put up their export rates to 60–100 per cent. above pre-war rates, to be paid *in English money*, and by some firms payment in advance is insisted upon. This is more than confirmed by Messrs. Bellingham and Stanley in their letter. What more do our manufacturers want?

The German goods are sold simply because they are superior to similar goods produced at reasonable prices in Britain. Mr. B. H. Morphy and Mr. C. Baker state that this was the case before the war, and most scientific workers will tell them that it is so still.

One firm complains of a voluntary hospital buying apparatus cheaper abroad, and thinks that an English firm should have been given the contract at higher rates. Whose money is to do this? I hope that the voluntary subscribers would protest against their money being paid to subsidise British manufacturers.

A small concrete example of what actually occurs may not be out of place. A German diamond object marker before the war cost 10 marks. Early this year I sent to a leading firm of British opticians for one. It arrived, but was absolutely useless, having no spring safety device and no means of screw adjustment, both present in the German one. It cost 1l. 10s. Months later, with considerable trouble, I procured from Messrs. Leitz, of Germany, the pre-war article at 100 per cent. advance, namely, 1l. The German article was bought because it was superior, not because it was cheaper.

It should be borne in mind that some scientific articles, *e.g.* photographic plates, can be produced well and cheaply here, and need not fear German competition. If, as Mr. Baker states, the profit on other classes of goods is too small, why not allow them to be imported from Germany?

Glasgow, May 21. J. S. DUNKERLY.

Cost of Scientific Publications.

LIKE other societies which exist mainly for the publication of the results of scientific research, the Royal Society of Edinburgh finds its activities greatly hampered by the present cost of publication. The statements contained in the leader in NATURE of May 6 and in the correspondence which has followed it are fully borne out by the experience of this society. Taking into account all present sources of income and all necessary expenses, it may safely be said that the output of scientific literature must be cut down to fully one-third of what it was in pre-war days.

The point to be emphasised is that publication of scientific results is absolutely necessary for the true development of science. A year and a half ago the council of the Royal Society of Edinburgh, on realising the seriousness of the situation, appealed to the Chancellor of the Exchequer for an increase in the annual grant solely in the interest of scientific publication. The appeal was unsuccessful, but in reply the Chancellor of the Exchequer stated that "he would be ready to reconsider the question along with other similar claims when the financial situation is more favourable."

It certainly seems necessary that suffering societies which publish original memoirs should take steps to press on the attention of the nation and on the conscience of the Government this consideration in the interest of scientific investigation, viz. the provision of adequate funds for the publication of the results of research.

C. G. KNOTT,
General Secretary.

Royal Society of Edinburgh,
22 George Street, May 31.

Natural History Studies in Canada.[1]

(1) A REVISED edition of Mr. Ernest Thompson Seton's "Arctic Prairies" (first published in 1911) is very welcome. It is a well-told story of a canoe journey of 2000 miles in search of the caribou (a kind of reindeer), and it discloses a cheerful picture of the abundance of wild life (in 1907) in the Far North-west of America. "I have lived in the mighty boreal forest, with its Red-men, its Buffalo, its Moose, and its Wolves; I have seen the Great Lone Land with its endless plains and prairies that do not know the face of man or the crack of a rifle; I have been with its countless lakes that re-echo nothing but the wail and yodel of the Loons, or the mournful music of the Arctic Wolf. I have wandered on the plains of the Musk-ox, the home of the Snowbird and the Caribou."

FIG. 1.—The sandhill crane. From "Wild Life in Canada."

The author has fine things to tell us of—such as the love-song of Richardson's owl, sung on the wing, "like the slow tolling of a soft but high-pitched bell"; a herd of wild buffalo amid a great bed of spring anemones; a troop of caribou, about 500 strong, charging at full trot through the taint of man; and the wealth of flowers in the so-called "Barren Grounds." There are grim pictures too—of the malignancy of the mosquitoes which for two and a half months make a hell of a land which for half the year might be an earthly paradise; of the epidemics that periodically wipe out the all too prolific rabbits (billions in the Mackenzie River valley in 1903–4, and none to be seen in 1907); of the Canadian lynx that "lives on rabbits, follows the rabbits, thinks rabbits, tastes like rabbits, increases with them, and on their failure dies of starvation in the unrabbited woods"; of the aged dwarf spruces which testify to the rigour of the environmental conditions, for one which was at least 300 years old was only 8 ft. high and 12 in. through. Mr. Seton's skill as a descriptive naturalist needs no praising, and his narrative is full of human interest as well. The book is generously illustrated with pen-and-ink drawings and photographs. The reference in the preface to the scientific appendices might have been ju[illegible] for appendices there are none.

(2) Capt. Buchanan tells of his wanderings in "the great unpeopled North, which even to-day comprises more than half of the large Dominion of Canada." He explored the country between

[1] (1) "The Arctic Prairies: A Canoe-Journey of 2000 Miles in Search of the Caribou. Being the Account of a Voyage to the Region North of Aylmer Lake." By Ernest Thompson Seton. Pp. xii+308. (London: Constable and Co., Ltd., 1920.) Price 8s. 6d. net.
(2) "Wild Life in Canada." By Capt. A. Buchanan. Pp. xx+264. London: J. Murray, 1920.) Price 15s. net.

the Saskatchewan River and the Arctic "Barren Grounds," and his collection of birds from the area drained by the Churchill River was the first to be made from that remote region. Of this collection a list is given at the end of the book, and birds predominate throughout the pages of what is really a naturalist's journal—unvarnished, graphic, and with a strong personal note. A chapter is given to the rare sandhill crane, which he saw and heard and stalked. He found the nest and saw the eggs through the field-glass, but, having waited overnight in the hope of the parents returning, he was baulked in the end, for the nest was empty in the morning.

A fine picture is given of Reindeer Lake, a vast sheet of water stretching 140 miles north and south, and 40 miles across at its widest. Its shores form the favoured winter-haunt of the barren-ground caribou (*Rangifer arcticus*), which digs through the snow to get at the white moss and marsh grass. Early in the year the does and yearling fawns begin to move northward, and the bucks follow later.

There is no weather-change urging the northward migration, so it is leisurely; moreover, many of the does are with young. The southward movement of great herds in the fall is largely conditioned by the absence of trees, for an icy crust, difficult to break, forms over the snow. "As the thermometer drops in the Far North and food and shelter become difficult to find, the animals will band together and grow restive, and pause from time to time to sniff the wind from the south with question on their countenance. And one day, with proud heads up and anxious eyes, they will commence their long travel through sheltering forests where snows are soft and food is plentiful beneath its yielding surface."

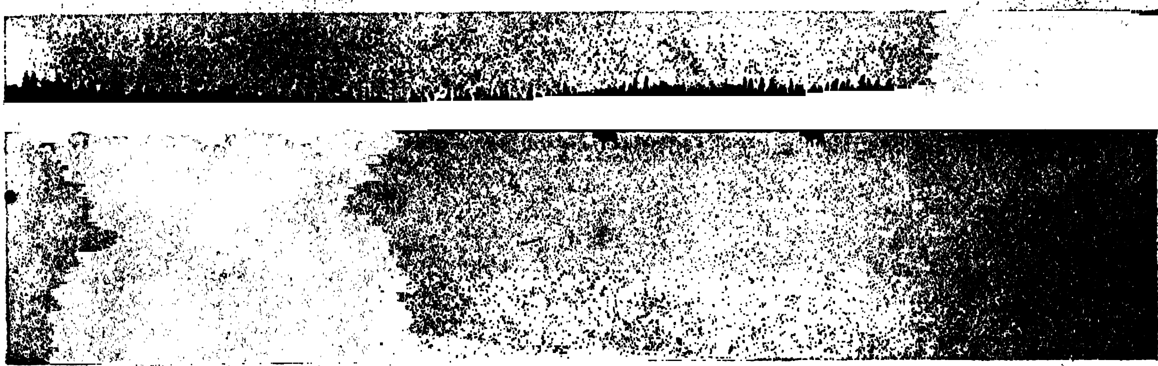

FIG. 2.—Caribou travelling in typical Indian file. From "Wild Life in Canada."

The picture that the author gives of the caribou is a fine piece of work. Another chapter deals with the admirable sled-dogs, which will gamely do their best, for two or three days on end, in bitter weather and without food, to save an anxious situation. Very good reading, too, is Capt. Buchanan's appreciation of the Cree and Chipewyan Indians, "quaintly friendly and unselfish in their hospitality," "resourceful, magnificent fellow-travellers on the trail."

Tidal Power.

THE idea of utilising the rise and fall of the tides for power purposes has long been a favourite one. Up to the present, however, no power development of this kind, of any appreciable size, has been carried out. The comparatively recent arousing of interest in water-power development in general, and the great advance in the cost of fuel, have been accompanied by a corresponding interest in tidal-power schemes, and their commercial possibility is at the moment the subject of serious investigation in this country and in France.

The power which may be developed from a tidal basin of given area depends on the square of the tidal range, and since the cost per horse-power of the necessary turbines and generating machinery increases rapidly as the working head is diminished, the cost per horse-power of a tidal-power installation, other things being equal, will be smallest where the tidal range is greatest. It is for this reason that the western, and especially the south-western, coasts of Great Britain, and the western coast of France, are particularly well adapted for such developments, since the tidal range here is greater than in any other part of the world, with the possible exception of the Bay of Fundy, Hudson's Bay, and Port Gallegos, in Patagonia.

In Great Britain the highest tides are found in the estuary of the Severn, the mean range of the spring tides at Chepstow being 42 ft., and of the neap tides 21 ft. In France the maximum range occurs at St. Malo, where it amounts to 42.5 ft. at spring tides, and about 18 ft. at neap tides. The tidal range in the Dee is 26 ft. at springs, and 12 ft. at neaps, while the mean range of spring tides around the coast of Great Britain is 16·4 ft., and of neap tides 8·6 ft.

Many schemes of tidal-power development have been suggested from time to time. Briefly outlined, the more promising of these are as follows:—

(*a*) A single tidal basin is used, divided from the sea by a dam or barrage, in which are placed the turbines. The basin is filled through sluices during the rising tide. At high tide the sluices are closed. When the tide has fallen through a height the magnitude of which depends on the working head to be adopted, the turbine-gates are opened, and the turbines operate on a more or less constant head until low tide. The maximum output from a given area of basin is

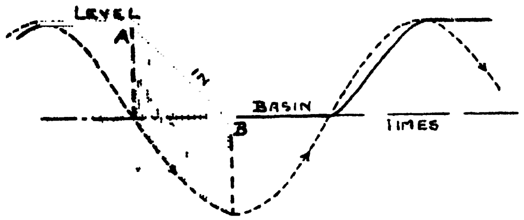

Fig. 1

obtained when the working head is approximately one-half the tidal range, and the cycle of operations under these conditions, and with a constant rate of fall in the tidal basin, is shown in Fig. 1. Here the dotted sine curve represents the level of the sea on a time base. The working period extends from A to B.

(*b*) A single tidal basin is used, with the turbines operating on both rising and falling tides. The cycle of operations is now indicated in Fig. 2. The working period per complete tide extends from A to B and from C to D. Slightly before low water, at B, the basin is emptied through

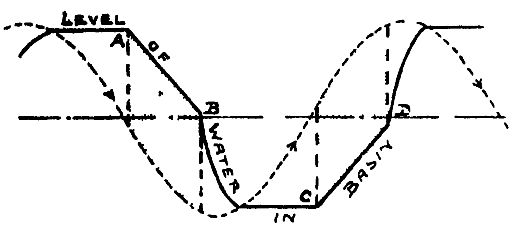

Fig. 2

sluice-gates, and at D, a little before high water, the basin is filled through the sluice-gates. With a working head equal to one-half the tidal range, the period of operation is approximately 50 per cent. greater than in system (*a*), and the work done per complete tide is approximately 50 per cent. greater.

(*c*) A single tidal basin is used with the turbines operating on both rising and falling tides. Instead of filling and emptying the tidal basin through sluice-gates at high and low water, and working under an approximately constant head, the water is allowed to flow through the turbines and to adjust its own level. Under these conditions the rise and fall inside the basin are cyclical, with the same period as the tide, but with a smaller rise and fall and with a certain time-lag. The range in the basin and the time-lag depend on the ratio of the surface area of the basin and of the effective discharge area of the turbines. The working head during each tide varies from zero to a maximum. The cycle of operations is shown in Fig. 3. The working period is from A to B and from C to D, where the head at the points A, B, C, and D is the minimum under which the turbines will operate. The total working period per tide is greater than with either of the preceding

Fig. 3.

systems, and the possible output is somewhat greater. On the other hand, the variation of head during any one tide is very large.

(*d*) Two tidal basins of approximately equal areas are used, with turbines in the dividing wall Each basin communicates with the sea through suitable sluice-gates. In one of these basins, called the upper, the water-level is never allowed to fall below one-third of the tidal range, while in the lower basin the level is not allowed to rise above one-third of the tidal range. The working head then varies from 0·53 H to 0·80 H, and operation is continuous, as indicated in Fig. 4, which shows the cycle of operations. The upper

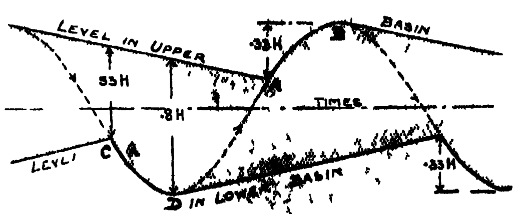

Fig. 4.

basin is filled from the sea through the appropriate sluice-gates from A to B, and the lower basin discharges into the sea from C to D. For a given total basin area and a given tidal range the output is only about one-half that obtained in system (*a*), and one-third that obtained in systems (*b*) and (*c*), so that, except where the physical configuration of the site is particularly favourable, the cost per horse-power is likely to prove very high.

(*e*) Two tidal basins of approximately equal size are used. Turbines are installed in the walls dividing the sea from each basin. Fig. 5 shows

the cycle of operations. From A to B the upper basin discharges through its turbines into the sea. From B to E the sea enters the lower basin through its turbines. The upper basin is filled from the sea through its sluice-gates between C and D, and the lower basin is emptied through its sluice-gates from F to G. The head varies from 0·25 H to 0·62 H, and the output is some 25 per cent. greater than in system (*d*), but the number of turbines required is much greater than in (*d*).

It is possible, at the expense of additional complication, to arrange in each of these systems that the head shall be maintained constant during any one working period, but since this means that the working head must then be the minimum obtaining during the period, a loss of energy is involved, with a great additional cost of construction and complication in manipulation, and with little compensating advantage.

The great difficulty in developing a tidal scheme as compared with an orthodox low head water-power scheme arises from the relatively great fluctuations in head. In any scheme in which the working head is a definite fraction of the tidal range, the working head at spring tides is much

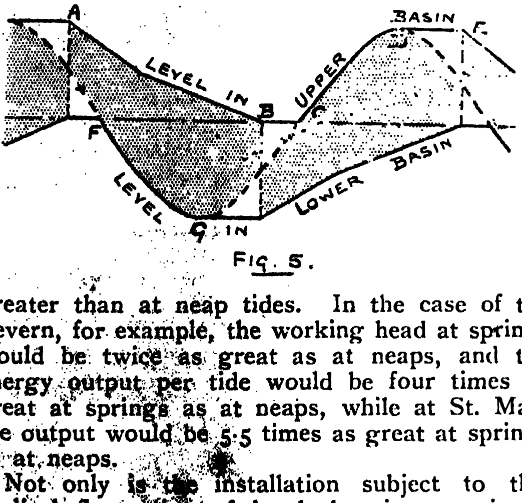

FIG. 5.

greater than at neap tides. In the case of the Severn, for example, the working head at springs would be twice as great as at neaps, and the energy output per tide would be four times as great at springs as at neaps, while at St. Malo the output would be 5·5 times as great at springs as at neaps.

Not only is the installation subject to this cyclical fluctuation of head, but in any simple scheme the turbines also cease to operate for a more or less extended period on each tide; and as this idle period depends on the time of ebb or flood tide it gradually works around the clock, and will, at regular intervals, be included in the normal industrial working day. It is true that schemes of operation such as have been indicated are feasible in which this idle period may be eliminated and continuous operation ensured, but only at a considerable reduction of output per square mile of tidal basin area. Even in such schemes, unless the working head is fixed with reference to the tidal range at neap tides, the variation of head between springs and neaps causes the output to be very variable.

In any installation, then, designed for an ordinary industrial load, unless the output is cut down to that obtainable under the minimum head available at the worst period of a neap tide, in which case only a very small fraction of the total available energy is utilised and the cost of the necessary engineering works per horse-power will, except in exceptionally favourable circumstances, be prohibitive, some form of storage system forms an essential feature of the scheme.

Various storage systems have been suggested. Electrical accumulators must be ruled out, if only on account of the cost, and the same applies to all systems making use of compressed air. The only feasible system appears to consist of a storage reservoir above the level of the tidal basin. Whenever the output of the primary turbines exceeds the industrial demand, the excess energy is utilised to pump water into the reservoir, and when the demand exceeds the output from the primary turbines it is supplied by a series of generators driven by a battery of secondary turbines operated by the water from the storage reservoir.

Evidently this method is available only when the physical configuration of the district affords a suitable reservoir site within a reasonable distance of the tidal basin. Unfortunately also, considerable losses are inevitable in the process, and the energy available at the switchboard of this secondary station is only about 50 per cent. of the energy of the water utilised by the primary turbines. Where two tidal schemes at some distance apart differ sufficiently in phase, it is possible, by working the two in conjunction, to reduce or eliminate the idle period between tides, and thus to reduce the necessary storage somewhat; but this does not affect the necessity of storage as between spring and neap tides.

Since storage reduces the available output by one-half, and at the same time complicates the system, besides adding considerably to the first cost and maintenance charges, the prospects of tidal-power schemes would be much more promising if the whole of the output could be utilised as it is generated. By feeding into a distributing main in conjunction with a large steam station and/or inland water-power scheme, and delivering to an industrial district capable of absorbing a comparatively large night load, such a state of affairs might be realised, at all events approximately. There is also the possibility that the intermittent operation of certain electro-chemical processes may be developed so as to enable any surplus power to be absorbed as and when available, and, if so, power developed tidally will probably prove cheaper in this country than that developed from any other source.

Owing to the relatively large variations in working head in any simple scheme, and to the small working heads, the design of hydraulic turbines capable of giving constant speed with reasonable efficiencies, and of moderately high speeds of rotation, is a matter of considerable difficulty. Modern developments, however, promise much better results in both these respects than would have appeared possible only a few years ago, and turbines are in existence

which are capable of operating under a variation of head equal to 50 per cent. on each side of the mean, with efficiencies which do not fall below 70 per cent. over this range, and with reasonably high speeds of rotation under the heads available.

Even with such turbines, the number of technical problems to be solved before a tidal scheme of any magnitude can be embarked upon with confidence is large. The questions of single- *versus* double-way operation, of storage, of the effect of sudden changes of water-level due to strong winds, of wave effects, of silting in the tidal basin and of scour on the down-stream side of the sluices, of the best form of turbine and of generator, and of their regulation and of that of the sluice-gates, are probably the most important, though not the only, subjects to consider.

On the other hand, the possibilities of tidal power, if it can be developed commercially, are very great. Assuming a mean tidal range of only 20 ft. at springs, and 10 ft. at neaps, and adopting the single-basin method of development with operation on both rising and falling tides, each square mile of basin area would be capable, without storage, of giving an average daily output of approximately 110,000 horse-power-hours. In such an estuary as the Severn, where an area of 20 square miles could readily be utilised with a spring tidal range of 42 ft., the average daily output, without storage, would be approximately 10,000,000 horse-power-hours.

At the present time it is difficult to obtain an even rough estimate of the total cost of such a scheme, owing to the uncertainty regarding many of the factors involved. The whole question would appear to merit investigation, especially on matters of detail, by a technical committee with funds available for experimental work. As a result of such an investigation, it is at least possible that a definite working scheme could be formulated capable of generating power at a cost at least as small as, and possibly much smaller than, that of power generated from any coal-fired installation.

Obituary.

Prof. C. A. Timiriazeff, For.Mem.R.S.

The death is announced of Clement Arkadievitch Timiriazeff, emeritus professor of botany in the University of Moscow. Timiriazeff was the only Russian botanist who was at all a familiar figure in England. In earlier days he came to England and saw Charles Darwin, while his last visit was made as a delegate to the Darwin celebration in Cambridge in 1909. His earliest publication appeared in 1863—a Russian book on "Darwin and his Theory," which ran through five editions. Here he made his mark as an attractive expounder of science for the general reader, and he followed this work with books on "The General Problems of Modern Science," "Agriculture and Plant Physiology," and "The Life of the Plant." The last was in great demand, there being seven Russian editions between 1878 and 1908, while in 1912 it was translated into English, and is widely read to the present day. Its characteristic note is an exposition of plant structure and function based on the chemical and physical processes at work in the living plant. Without comparison of the early editions we cannot tell at what date this book took the form in which it appeared in English, but it looks as if Timiriazeff was one of the earliest writers to take up this essentially modern outlook. His attitude was no doubt an expression of his early training under chemists and physicists. Born in 1843, he studied under Bunsen, Kirchhoff, Helmholtz, and Berthelot before working with Boussingault.

Timiriazeff made himself famous by work on one single problem—the participation of the different rays of the visible spectrum in the photosynthetic activity of the green leaf. The technique which he brought to the attack on this problem seems almost an exact expression of the combined influence of his teachers: good methods of gas-analysis, pure spectral illumination, and experimentation on isolated leaves; combined with the sound conception that rays utilised for work in the chloroplast must be rays abundantly absorbed by the pigment chlorophyll. Working with a micro-eudiometer, concentrated sunlight, and a narrow spectroscope slit, he was able to disprove the accepted view that the yellow region, which is so bright to the eye, is the most effective region of the solar spectrum, and to locate the efficiency in the red region where absorption by chlorophyll is greater. Afterwards he demonstrated the secondary maximum of photosynthetic effect in the blue region, where also absorption is great.

This work was published in different forms, at various dates, in scientific journals of most European countries, the final presentation being the Croonian lecture to the Royal Society in 1903. The actual experimental work seems to have been all done between 1868 and 1883. There is no evidence that he published research work on any other subject, so that we have in Timiriazeff the remarkable case of a man who, having achieved fame by one important line of research at forty, was content to devote the remaining half of his life to teaching and exposition.

The announcement of a new book, "A Nation's Heritage," by Hardwicke Drummond Rawnsley, sadly coincides with the record of its author's death. Born on September 28, 1851, the distinguished canon died on May 28, to the last pursuing the self-imposed task of persuading his fellow-countrymen to take care of their own treasures. His mother was a niece of Sir John Franklin, the Arctic explorer. In education Canon Rawnsley had the good fortune to be at Upping-

ham under Edward Thring, and at Balliol under Benjamin Jowett, with fellow-undergraduates who in various ways became men of light and leading. As a poet and preacher, and in general a quickener of life and energy wherever demands were made upon his active genius, he met with well-deserved appreciation. As the obituary notice in the *Times* observes, "perhaps his chief work was the founding of the National Trust for the Preservation of Places of Historic Interest and Natural Beauty." For the qualifying word "perhaps" it would be better to substitute the word "undoubtedly." Men like Canon Rawnsley, by setting a courageous example, often accomplish much more than their immediate object.

By the death, at fifty-eight years of age, of Dr. George Ernest Morrison, "Morrison of Peking," as he was familiarly known, the Empire has lost a great explorer and expert in the politics of the Far East. An Australian by birth, Dr. Morrison began by explorations in that continent, New Guinea, and the South Sea Islands, his most notable exploit being his famous crossing from the Gulf of Carpentaria to Melbourne in 1882, when he marched 2043 miles on foot in 123 days. Coming to Europe, he took his degree of M.D. at Edinburgh, and wandered in the United States, Spain, and Morocco. Reaching China, he crossed to Rangoon and explored Siam. His life-work really began in 1897, when he was appointed correspondent of the *Times* at Peking. Here he recorded from day to day with the prescience of a statesman and the accuracy of a historian the momentous struggle which resulted from the German occupation of Kiao-chao, and he took an active part in the defence of the Peking Legations during the Boxer rising of 1900. In 1907 Dr. Morrison crossed China from Peking to Tonquin, and in 1910 he rode from Honan City to Andijan in Russian Turkestan. Two years later he resigned his post as correspondent of the *Times*, and became political adviser to the first President of the Chinese Republic. During his stay in Peking he collected one of the most comprehensive libraries of Chinese literature. His contributions to the study of the Far East, except his well-known book, "An Australian in China," largely consist of newspaper articles.

We much regret to announce the death, on May 28, in his forty-third year, of Prof. Leonard Doncaster, F.R.S., fellow of King's College, Cambridge, and Derby professor of zoology in the University of Liverpool.

We notice with regret the announcement in the *Times* of the death in India, at the early age of thirty-two years, of Prof. Srinivasa Ramanujan, F.R.S., fellow of Trinity College, Cambridge, and distinguished by his brilliant mathematical researches.

Notes.

The Romanes lecture at Oxford was delivered on May 27 by Dr. Inge, Dean of St. Paul's, before a large audience, by whom the lecturer's brilliant epigrams and trenchant criticism of conventional catchwords were evidently much appreciated. Dealing with the "idea of progress," the Dean made it clear that he had no belief in any natural law of continued progress in the sphere of morals or intellect, or even of physical organisation. The conception of such a law was, in fact, of comparatively recent growth, and had no foundation in the thought of antiquity or of the Middle Ages. At the same time he would not deny a temporary improvement of the race in fulfilment of a finite purpose, though he found little or no evidence of any advance during the historical period in either physical organisation or morals. The results of accumulated experience must not be confounded with a real progress in human nature. Dean Inge would scarcely be concerned to deny that the emergence of rational humanity from previous non-human conditions deserved in some sort the name of "progress," but he saw no warrant for the belief that such "progress" would be continued indefinitely under the domain of natural law. Huxley had pointed out in a previous Romanes lecture that ethical improvement ran counter to the process of cosmic evolution. Progress was a task for humanity, not a law of Nature. Civilisation was a disease that had hitherto been invariably fatal. The ancient civilisations had fallen by the attacks of outer barbarians; "we breed our own barbarians." But progress was possible for the individual, if not for the race, and hope was not only a virtue, but also a solid fact.

On May 17 Mr. H. Morris, of Lewes, read a paper to the Oxford University Archæological Society on the evolution of Wealden flint culture from pre-Palæolithic times, including that of Piltdown Man. He exhibited many flints, which he claimed as intermediate between the early Harrison types of the North Downs plateau and the recognised Palæolithic types, representing man's transition from the stage in which he subsisted on a vegetable diet to the hunting stage. The earliest spear-head accompanies the Piltdown skull and marks the beginning of man the hunter. The flints are confined to a limited number of patches, and many prolific "river gravel" areas fail to produce anything resembling them; the proportions in which the various types appear are found to agree closely in all the patches. When the cortex of the flint did not interfere with the design of the implement, it has been cleverly and intentionally preserved; many of the fractures are of thermal origin, but man utilised these natural fracture-surfaces in the same way as he utilised cortex. It is significant that signs of man's work appear only in the places where it is essential for the attainment of the required form. Sir Arthur Evans, Prof. Sollas, Dr. Marett, Mr. Henry Balfour, Mr. Reid Moir, and others discussed Mr. Morris's paper, and hesitated to accept his conclusions.

A SUDDEN flood swept through the Lincolnshire town of Louth on Saturday afternoon, May 29, causing immense havoc in its path. The torrent took the course of the small stream known as the River Lud, which runs through the town, and rose 15 ft. in half an hour. The disaster, which occurred shortly before 5 o'clock, is described as a huge wall of water sweeping down upon the town and carrying away bridges and buildings opposed to its course. The River Lud in normal times is a stream from 12 ft. to 15 ft. wide, and about 2 ft. or 3 ft. deep. The flood is said nowhere to have been less than 8 ft. to 10 ft. high and fully 200 yards wide. It was apparently accompanied by no warning sound, and the torrent of water is said to have exceeded the rate of 40 miles an hour. The loss of life is reported to be from 25 to 40 persons, and the damage to property is roughly estimated at 250,000*l*. to 500,000*l*. A heavy thunderstorm had raged for two hours in the afternoon. The disaster was, without doubt, due to intense thunderstorm rains swelling the river far beyond the capacity of its channel. The "Meteorological Glossary" published by the Meteorological Office describes a "cloud-burst" as a term commonly used for very heavy thunder-rain, and in this sense the term seems applicable to the cause of the Louth disaster.

THE new by-laws of the Chemical Society came into force on June 1, and women are now eligible for fellowship of the society.

THE annual visitation of the Royal Observatory, Greenwich, will be held on Saturday next, June 5. The observatory will be open for inspection by invited visitors at 3.30 p.m.

DR. FREDERICK G. COTTRELL has been nominated by President Wilson as Director of the U.S. Bureau of Mines, Department of the Interior, in succession to Dr. Van. H. Manning, resigned.

THE Stewart prize of the British Medical Association has been awarded by the council to Dr. Harriette Chick, who has been an assistant in the department of experimental pathology at the Lister Institute since 1906, and has published numerous papers on bacteriology and physical chemistry.

BY the courtesy of the council of the Institution of Mechanical Engineers, the next ordinary scientific meeting of the Chemical Society on June 17 at 8 p.m. will be held in the lecture-hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1, when Prof. J. C. McLennan, of Toronto University, will deliver a lecture on "Helium."

A JOINT meeting of the Association of Economic Biologists and the Imperial Entomological Conference will be held at the Rothamsted Experimental Station, Harpenden, on June 4. The party will leave St. Pancras Station by the 10 a.m. train and, on arrival at Harpenden, proceed direct to the park, where the experimental plots will be demonstrated by Dr. W. E. Brenchley.

SIR WILLIAM J. POPE has accepted the nomination of the council of the Society of Chemical Industry to be president for the year 1920–21. Prof. H. Louis has been elected foreign secretary in succession to the late Dr. Messel, and Dr. C. C. Carpenter has been appointed the society's representative on the governing body of the Imperial College of Science and Technology.

AT the meeting of the Franklin Institute, Philadelphia, on May 19, the Franklin medal awarded to the Hon. Sir Charles A. Parsons was received by Sir Auckland Geddes, British Ambassador; and Mr. W. A. F. Ekengren, Swedish Minister, also received a Franklin medal for Prof. Svante A. Arrhenius. Papers were presented on "Some Reminiscences of Early Days of Turbine Development" by Sir Charles A. Parsons, and on "The World's Energy Supply" by Prof. Arrhenius.

THE national memorial to the late Capt. F. C. Selous at the Natural History Museum, Cromwell Road, South Kensington, will be unveiled by the Right Hon. Viscount Grey of Fallodon, K.G., on Thursday next, June 10, at 3.30 p.m. The presentation will be made by the Right Hon. E. S. Montagu, M.P., chairman of the committee. The granite of the bas-relief which forms the memorial is from the Matoppo Hills, the burial-place of Cecil Rhodes and Sir Starr Jameson, and was presented to the Selous Memorial Committee by the Government of the Union of South Africa.

THE Imperial Entomological Conference was opened in London on Tuesday, June 1, by Lord Harcourt. The official delegates to the conference are:—Canada, South Africa, Basutoland, Bechuanaland, and Swaziland, Mr. C. P. Lounsbury; Australia, Prof. R. D. Watt; New Zealand, Dr. R. J. Tillyard; India, Mr. C. F. C. Beeson; Queensland, Mr. F. Balfour Browne; British Guiana, Mr. G. E. Bodkin; Ceylon, Mr. F. A. Stockdale; East Africa Protectorate, Mr. T. J. Anderson; Federated Malay States, Mr. P. B. Richards; Gold Coast, Mr. W. H. Patterson; Imperial Department of Agriculture for the West Indies and Leeward Islands, Mr. H. A. Ballou; Mauritius, Mr. G. G. Auchinleck; Northern Rhodesia, Dr. Aylmer May; Southern Rhodesia, Mr. R. W. Jack; Seychelles, Dr. J. B. Addison; Sierra Leone, Mr. H. Waterland; Straits Settlements, Mr. P. B. Richards; Sudan, Mr. H. H. King; Trinidad, Mr. F. W. Urich; and Uganda, Mr. C. C. Gowdey.

IN the May issue of the *Fortnightly Review* Mr. Edward Clodd gives an account of the prevalence of occultism at the present day. This results from the fact that though man calls himself *Homo sapiens*, his instincts and elemental passions and emotions remain primitive. Prof. Elliot Smith in a recent paper on "Primitive Man" remarks that, "so far as one can judge, there has been no far-reaching and progressive modification of the instincts and emotions since man came into existence beyond the acquisition of the necessary innate power of using more complex cerebral apparatus which he has to employ." *Plus ça change, plus c'est la même chose.* The influence of the present movement, and the mischievous play on the hopes and fears of crowds of dupes of all classes of society, are strongly reprobated. "Its exponents lack the harmlessness of the cranky theory-

mongers who, if they have wasted our time in the pamphlets they thrust upon us, at least in some degree condone this nuisance by the amusement which they supply."

SIR W. RIDGEWAY AND DR. L. D. BARNETT have reprinted a paper read by them before the Cambridge Philological Society on "The Origin of the Hindu Drama: Additional Evidence." The theory that this type of drama had its origin in dances connected with the cult of the dead is supported by a new series of facts. Krishna, whether he be regarded as a deity from all time or merely a vegetation abstraction, was, as was suggested by S. Lévi in 1892, the chief element in the Hindu drama. The defeat of the Asura demons by Indra took a dramatic form, in which the god's flagstaff became the emblem of the stage, recalling the pole known to the Japanese as Mitegura, "Lordly-Cloth-seat," and to the Chinese Gohei, "Imperial Presence." In the same way the Vīr, or spirits of men who died on the battlefield, are "danced" by the Mahrattas. Other evidence to the same effect has been collected from other parts of India, and the writers sum up the discussion by remarking that "there can therefore be no longer any doubt that Hindu serious drama arose in the worship of the dead."

IN the Journal of the Royal Society of Antiquaries of Ireland (vol. xlix., part 2, December, 1919) Mr. R. J. Kelly, K.C., discusses the question of the famous Donnybrook Fair. On the authority of the great Irish scholar, Dr. Todd, the name seems to be derived from Domhnach broc, "the Church of Broc," a saint who seems to have flourished before the eighth century. By a charter of Prince John, bearing date 1192, the city of Dublin was authorised to establish a fair "at Doniburn annually to continue for eight days on the Feast of the Invention of the Holy Cross," and this was confirmed by a charter, 26th of Henry III., dated 1241. The rude merriment, crime, and degradation which occurred during the fair finally led to its abolition in 1855, after it had lasted nearly six and a half centuries. Mr. Kelly's article contains an excellent collection of extracts from contemporary writers describing the famous fair. Further details are given in the same issue of the journal in an article by Mr. H. Bantry White on "An Old House at Donnybrook."

MISS ANNE L. MASSY gives (Sc. Proc. Roy. Dublin Soc., vol. xvi., No. 4, April, 1920) a revised list of the twenty-five species of Holothurioidea ("sea-cucumbers") of the coasts of Ireland. Since the publication in 1905 of Mr. Kemp's paper on the Echinoderms of the west coast of Ireland, the naturalists of the Fisheries Branch of the Department of Agriculture have taken three species of Holothurians which are new to the British and Irish area, namely, *Stichopus regalis*, *Mesothuria Verrilli*, and *Benthogone rosea*. The first of these occurs in the Mediterranean, and is known as far south as the Canaries, but has not hitherto been observed north of the Bay of Biscay. The other two appear to inhabit the warmer parts of the Atlantic, and probably reach their northern limit at about 52° N.

DR. H. A. PILSBRY'S "Review of the Land Mollusks of the Belgian Congo, chiefly based on the Collections of the American Museum Congo Expedition, 1909–1915" (Bulletin of the American Museum of Natural History, vol. xl., art. 1, 1919), is a very important contribution to our knowledge of the African fauna. The collections on which it is based are very extensive, comprising more than 6000 specimens representing 214 species and subspecies, and a complete record of all the land molluscs hitherto known from the region (compiled by Dr. J. Bequaert) is included. Large numbers of carefully preserved spirit-specimens were available, and Dr. Pilsbry was able to study the anatomy of the soft parts with important results. In the case of the Helicidæ, of which the tropical African representatives have hitherto been known by the shells alone, he has been able to show that their affinities are not, as had been supposed, with the European genera of the family, but with the Asiatic. The field notes are contributed by Mr. Herbert Lang, whose account of the bionomics, economic uses, and folk-lore of the giant Achatinidæ is of particular interest. His remarks on the dispersal of certain species over large areas by the agency of man are worthy of note as having possibly a wider application. The memoir is very fully illustrated, and some of the coloured plates are of exceptional beauty.

WE seem to have much to learn about even the commonest of marine organisms, and the exceedingly abundant and almost cosmopolitan protozoon Noctiluca—a frequent cause of luminescence in the sea—has just received at the hands of Prof. C. A. Kofoid, of the University of California, a new interpretation which, if accepted, will necessitate a change in classification involving the removal of that supposed Cystoflagellate from its accustomed position and its incorporation in another group of the Flagellata ("Noctiluca," Univ. of Cal. Publicns. in Zool., vol. xix., No. 10, February, 1920). Prof. Kofoid is the recognised authority on the groups in question, and no one is more competent to express an opinion on the matter. In describing several new and remarkable genera of the Dinoflagellata from the Pacific related to Gymnodinium, he points out that Noctiluca may have its essential morphological characters homologised with those of various new highly specialised tentacle-bearing forms, such as *Pavillardia tentaculifera*. Noctiluca, then, according to these new investigations, is not exceptional amongst Dinoflagellates in bearing a tentacle, and may be interpreted as having a girdle, a sulcus, and two flagella like any other more ordinary Peridinian. The statement, however, that the "tooth" or prehensile organ represents the degenerate transverse flagellum may possibly be regarded as open to doubt. The acceptance of this work means that the order Cystoflagellata, established by Haeckel in 1878 for the reception of Noctiluca, and adopted by most writers since, should be either suppressed or emended. Noctiluca is no longer its type for text-book and lecture.

A CONCISE record of botanical exploration in Chile and Argentina is given in the *Kew Bulletin* (1920, No. 2) by W. B. Turrill. Among the earliest explorers

were the French botanist, Philibert Commerson, who was surgeon and naturalist to Bougainville's expedition (1767–68), and Sir Joseph Banks, who with Daniel Solander accompanied Cook on his first voyage round the world (1768–71), and brought home extensive botanical collections from the southern hemisphere. The collections of the Spanish naturalists, Ruiz and Pavon, at the close of the eighteenth century were the foundation of an important work on the flora of Peru and Chile. John Miers spent several years in La Plata and Chile, accumulated a large herbarium (now at the British Museum), and published monographs of various South American families of plants. Charles Darwin visited Argentina, Chile, and Patagonia, and Sir Joseph Hooker in his work on the Antarctic flora contributed largely to our knowledge of the botany of the Magellanic area. Valuable botanical exploration was also carried out by collectors sent out by the firm of Veitch—William Lobb and Richard Pearce. The Philippis, father and son, worked for nearly fifty years, collecting and publishing extensively on the flora of Chile. These are a few only of the long list of botanists and collectors chronicled by Mr. Turrill, who, in conclusion, points out that there is still scope for botanical exploration, especially on the Argentine side of the Andes.

In view of the present high prices of sugar, considerable interest is being taken in the question of the possibilities of sugar-beet production in England. The Weekly Service for April 3 from the Ministry of Agriculture and Fisheries contains some useful information on this point. Even apart from the production of sugar, sugar-beet is a useful crop to grow. The food for stock would not be materially reduced by substituting sugar-beet for roots in the rotation, while both leaves and by-products make excellent cattle food. To ensure good crops the land has to be very thoroughly cultivated—a process which reacts favourably on subsequent crops—and there is the further advantage that the crop gives a direct monetary return. Extensive trials were made before the war, and these showed that many parts of the country are suitable for large-scale production of sugar-beet for the manufacture of sugar; but it must be clearly understood that, owing to the bulky nature of the crop and the consequent difficulties of transport, it is advisable to grow beet for sugar production only when the land is within reasonable transport distance of a factory.

Students of the continental deposits of the Old Red Sandstone and Triassic days may well take note of the illustrative matter provided in South Africa and described concisely by Mr. Wm. Torrance ("Observations on Soil Erosion," Union of S. Africa, Dept. of Agric., Bull. 4, 1919, price 3d.). The numerous photographs are small; but some, like that of the infilled vlei at Grootfontein, are highly suggestive.

Among the many well-produced Water-Supply Papers of the United States Geological Survey which have reached us are several dealing particularly with the surface water-supply for the year ending September 30, 1916. Work of this nature was begun many years ago in connection with studies of irrigation problems in arid areas, but a particular effort was made in 1915–16 to obtain synchronous observations of the flow of streams. The data supplied for each gauging station in the area covered by each report include a description of the station and tables giving the daily, monthly, and yearly discharge. Illustrations of current meters and water-stage recorders are given.

The reclamation of salt soils is an important agricultural problem in India. Without a soil survey it is impossible to say what area is affected, but in Sind, and to a less extent in the Punjab and the United Provinces, it must be considerable. These so-called alkali lands are either uncultivable or injurious to the growth of crops. "Notes on Practical Salt-Land Reclamation" is the title of a paper published as Bulletin No. 91 by the Agricultural Research Institute, Pusa. Mr. G. S. Henderson, the author of the paper, examines the methods employed in Egypt in the reclamation of Lake Aboukir in the Nile delta, and draws some useful conclusions as to comparable work in India. He insists that the Egyptian method of washing the salt into the subsoil is the only effective way of dealing with the problem. Periodical surface washing is unsatisfactory. It is pointed out, however, that until the Indus barrage is completed there is not enough water in Sind for this purpose, all the available supply being required for irrigation.

The Germans during the war, when materials were short, gave a certain amount of attention to the utilisation of blast-furnace slags, and succeeded in obtaining a satisfactory cement after many experiments. A new use for slag is foreshadowed in an article in *Stahl und Eisen* (March 4), viz. for the manufacture of light bricks for building purposes. By passing molten slag horizontally through water, the steam generated blows out or extrudes the slag jet, and forms what the Germans term "spume" slag or artificial pumice-stone. This material has been patented under the name of "thermosite," owing to its excellent heat-insulating properties. The patentee has also invented a press for pressing bricks formed of small pieces of this artificial pumice and a mixture of slag, sand, and slaked lime, which is used as a binder. The bricks thus formed are strong and light, and resemble in their properties the alluvial (tuff) stone obtained in the neighbourhood of Andernach. As, in addition, they can be pressed to large dimensions, less mortar will be required in building operations. The German authorities have approved of the new type of brick for house-building.

In the *Revue générale des Sciences* for April M. Florentin gives an interesting account of the French experience of German gas warfare, with full chronological details of its development and an account of the properties of the substances used, as well as of their mode of manufacture. The section of the French Gas Service under M. Kling, director of the Paris Municipal Laboratory, examined about 2400 samples of material, of which half were shells and projectiles, M. Grignard devoting himself specially to the detection

of impurities which might reveal the modes of manufacture. Reference is made to the Central Laboratory of the British at Hesdin under the late Prof. Watson, and the great rapidity with which new enemy materials were detected is attributed to the excellent *camaraderie* which always prevailed between the French and British Gas Services. The article also contains a summary of the report of the French Mission on the chemical works in the area of occupation, including statistics of the output. In conclusion, M. Florentin expresses the hope that the war has demonstrated the inseparability of chemistry and national defence and the importance of developing the scientific and industrial research which was initiated in France by gas warfare.

WE have received from Messrs. Wood Bros. Glass Co., Ltd., of Barnsley, a copy of their catalogue of English chemical glassware. The list of apparatus is a comprehensive one, well-arranged and neatly illustrated. Judging by the particulars given, chemists should have no difficulty in obtaining any of the usual flasks, beakers, burettes, gas pipettes, absorption tubes, or other glass instruments employed in the laboratory from the selection offered; and as regards any special apparatus in glass that experimenters may want the makers invite inquiry. Messrs. Wood are old-established glass manufacturers who took up the making of chemical glassware in 1915, and they claim that, following the indications given by Sir Herbert Jackson's work on the composition of various special kinds of glass, supplemented by the investigations of their own staff, they are able to produce ware superior to the best Jena glass in its resistance to the action of strong chemicals. It does not withstand sudden extreme changes of temperature quite so well, but will, it is claimed, stand being plunged whilst at a temperature of 150° C. into cold water, and this is more than sufficient for all ordinary requirements. The shapes and designs of ware adopted are those approved by the Glass Research Committee of the Institute of Chemistry, and it would appear generally that the aim of the makers is the praiseworthy one of producing apparatus of high quality in close relation to scientific needs. A feature is made of standard volumetric apparatus verified and stamped by the National Physical Laboratory.

MR. S. EVERSHED read a paper on permanent magnets in theory and practice to the Institution of Electrical Engineers on May 13. He practically adopts Ampère's theory that the molecules of iron in a magnet are equivalent to electric circuits of no resistance in which electric currents are always flowing. On this hypothesis, and adopting Hopkinson's formula connecting magneto-motive force, reluctance, and flux, he discusses the design and predetermination of permanent magnets. He points out that since in practice the demagnetisation curve of the steel is known, the problem that has to be solved is to find the shape of the minimum volume of steel required to produce a given quantity of external magnetic energy. By making assumptions as to the reluctance of the paths of the magnetic flux, Mr. Evershed proves that the performance of a permanent magnet can be predicted in certain cases with accuracy. We are not sure, however, whether this is due to the fact that the errors made in his assumptions cancel out one another. We fail to understand his formula for the magnetic conductance between two spherical poles. It would be true if they were at an infinite distance apart, but appreciable errors come in when the distance between them is less than a hundred times the radius of either. It is easy to show that the magnetic conductance between two spherical poles equals 4π times the electrostatic capacity between their surfaces. Hence, as the electrostatic capacities have been tabulated, the magnetic conductances could be written down at once with high accuracy. From the engineering point of view the paper is valuable, as the subject is of practical importance to manufacturers.

PROF. W. W. WATTS, lecturing to the South Kensington Branch of the National Union of Scientific Workers on May 27 on "The Evolution of the Bicycle," showed that the development of this, as of any mechanical apparatus, took a similar course to that observed in biological evolution. It was largely a process of trial and error; advance was usually in small details of specialisation, and, as in the case of the high bicycle, development was apt to take place in a "blind lead" by following out a wrong principle. The lecture will be reported in the next issue of the *Scientific Worker*, copies of which can be obtained from the Secretary, N.U.S.W., 19 Tothill Street, S.W.1, by sending a stamped addressed envelope.

KODAK, LTD. (Wratten division), have just issued a new series of nine circular light-filters to facilitate visual work with the microscope. They are 35 mm. in diameter, and so fit the standard turn-out ring usually available in sub-stage fittings. Six are for increasing the contrast in stained or coloured preparations, one is blue and serves for getting the highest resolving power, one a neutral tint for modulating the intensity of the illumination, and the ninth converts the light from metal filament vacuum lamps into the equivalent daylight. This last is also of service with other light sources, such as the new thorium pastille gas lamp and the usual paraffin lamps. Its use gives the same colour values as daylight, and so reduces or eliminates eye-strain when observations are long continued.

IN a small leaflet entitled "Radium Facts," received from Messrs. Watson and Sons, are collected numerous data relating to radio-active substances useful to intending purchasers. From it we learn that, whereas the total production of radium to date by the Standard Chemical Co., of Pittsburgh, was 50 grams of radium element, its present output is at the rate of 18 grams of the element per annum. We understand that this output could be increased to 50 grams of radium element yearly if the demand for such a quantity should arise—a very considerable national asset. It is interesting to observe that the present total available supply of high-grade purity radium in the world is estimated to be about 120 grams.

Our Astronomical Column.

RETURN OF TEMPEL'S COMET.—Tempel's second periodic comet, discovered in 1873, was detected by Mr. Kudara at Kyoto, Japan, on May 25d. 7h. 10m. G.M.T., in R.A. 20h. 55m. 7s., S. decl. 4° 53'. The approximate time of perihelion passage is 1920 July 10·36. The other elements are approximately as follows:—ω 186° 38' 43", Ω 120° 37' 59", i 12° 45' 17", ϕ 33° 54' 21", μ 685·881". The following ephemeris has been computed for midnight:

	R.A. h. m. s.	S. Decl. ° '	Log r	Log Δ

The comet is probably faint, but as it is approaching both sun and earth its brightness should increase perceptibly. It rises half an hour before midnight, and is fairly well placed for observation just before dawn.

DOUBLE STARS.—Since its erection in 1894, the 28-in. equatorial at Greenwich has been mainly used for the observation of double stars; the list included many of special difficulty owing to faintness or close proximity. Mr. J. Jackson has discussed the observations made at Greenwich and elsewhere in Monthly Notices for March, and publishes twenty revised orbits. One of the stars is Struve 2525, for which very discordant values of the period have been found. The new value, 354·9 years, is larger than those previously found, which range from 138 to 307 years. The semi-axis major is 1·1" and the eccentricity 0·93, so that at the time of periastron, 1887·3, the star could not be separated.

The star Struve 2055 had given much trouble to computers; two observations by Sir William Herschel in 1783 and 1802 were mutually inconsistent. Mr. Jackson has unearthed a note that the micrometer reading was not written down at the time, and that the reading entered may be wrong. The quadrant noted is shown to have been correct, and Herschel's other observation in 1802 is well satisfied. The period assigned is 110 years and the eccentricity 0·86.

With respect to notation, he directs attention to diversity in the method of reckoning the angle ω, and recommends the general adoption of the system used by Campbell, Aitken, and Hussey, in which it is measured in the direction of motion in the orbit plane.

DIFFRACTION IMAGE OF A DISC.—Mr. H. Nagaoka contributes a useful article on this subject to the *Astrophysical Journal* for March. Diagrams of the "isophotes" are given, and it is shown that the results explain the black drop observed in transits of Venus, and the projection of bright stars upon the moon's disc that has often been observed in occultations at the illuminated limb. A striking case of this phenomenon has lately been noted in the reappearance of the star Leipzig I 4091 from behind Saturn on March 22 last. Messrs. Reid, Dutton, and McIntyre, observing in South Africa, saw the star reappear within the limb of the planet, its conspicuous orange colour facilitating its detection. They give the explanation that the outer portion of Saturn is composed of transparent clouds, but it would seem that the expansion of the disc by diffraction is sufficient to account for it. (B.A.A. Journal, April.)

It is of interest to note that in South Africa the star at disappearance passed behind the ring, while in Europe, owing to parallax, it did not. It was clearly visible through the ring, showing that the separate particles composing the ring are not very densely massed.

Monument to Charles Gerhardt.

NOW that Alsace is once more united to France, it is peculiarly fitting that Strasbourg, his native place and where he lies buried, should be the site of the long-delayed monument it is proposed to erect to the memory of Charles Gerhardt. British chemists who are at all familiar with the history of their science scarcely need to be reminded of the part played by Gerhardt in its development, or of the influence which his writings exercised in the search for methods of elucidating the structure and constitution of chemical compounds.

His "Traité de Chimie organique" may be said to mark an epoch; it was a significant feature of a movement which characterises the middle of the nineteenth century, and which the book itself greatly accelerated. Although much of its teaching, as the systematised expression of the facts of organic chemistry, is obsolete, the work is, and will remain, a classic, for it forms the basis upon which the superstructure of modern chemistry is erected. Gerhardt, however, was not only a speculative philosopher of the highest type; he was also an experimentalist of uncommon power and insight who framed his theoretical conceptions in the light of his own ascertained facts, and tested them by further investigations designed either to substantiate or to disprove them. His name is associated with the discovery of many new substances, some of which, like the acid anhydrides, are of the greatest theoretical and practical importance. It may be claimed for him that, together with Dalton and Berzelius, he was one of the principal founders of the atomic theory and the originator of the notation which immediately flows from it.

An influential committee has now been formed to discharge the debt—long overdue—which the chemical world owes to Gerhardt's memory. It comprises the names of some of the most eminent of French men of science and of those of Allied countries, under the presidency of M. Armand Gautier, member of the Institute, with an executive consisting of M. Haller, member of the Institute, as chairman; M. Chenal, treasurer of the French Chemical Society, as treasurer; and M. Tiffeneau, assistant professor of the Faculty of Medicine, as secretary. The object is well worthy of the consideration of British chemists, and may be specially commended to the notice of the Chemical Society and the Society of Chemical Industry if these bodies have not already responded to the appeal.[1]

T. E. THORPE.

Biological Papers from Bengal.

THE publications of the Asiatic Society of Bengal during the years 1916 to 1919, which we have lately received for review, contain a large number of contributions to biology, showing an activity in this department that has not been surpassed before. If we consider also the publications issued by the Indian Museum, the Calcutta Botanic Gardens, and the flourishing Bombay Natural History Society, we have reason to rejoice over the prosperous state of this branch of knowledge in our Indian Empire. Allusion should be made also to the enterprise of Dr. N. Annandale, who, alone or with other members of the Zoological Survey of India, of which he is the director, has in the last seven years investigated the

[1] A circular signed by Sir James J. Dobbie, president of the Chemical Society, has just been issued inviting fellows of the society to contribute to the memorial fund. Such contributions should be sent to the Treasurer, Chemical Society, Burlington House, London, W.1.—ED. NATURE.

macroscopic fauna of various Asiatic lakes, with results that are of the greatest interest.

The Asiatic Society of Bengal issues Memoirs in quarto, and Journal and Proceedings in octavo. In the Memoirs, parts ii. to v. of Dr. Annandale's "Zoological Results of a Tour in the Far East" further testify to the author's wonderful activity and versatility, which are known to all zoologists. In these parts he deals himself with the Hydrozoa and Ctenophora, the Batrachia, the Sponges, and the Mollusca, together with additions to ethnography; whilst other groups have been entrusted to C. A. Paiva (aquatic Hemiptera), Col. J. Stephenson (aquatic Oligochæta), Dr. Asajiro Oka (Hirudinea), Sir Charles Eliot (Mollusca Nudibranchiata), Tokōi Kaburaki (brackish-water Polyclads), and Stanley Kemp (Crustacea Decapoda and Stomatopoda). Numerous text-figures and five plates illustrate these contributions.

Dr. Annandale's paper on the Hydrozoa and Ctenophora is one of special interest, our knowledge of the Oriental fresh-water forms of these two groups being of rather recent date, and, as the author observes, still very imperfect. A new Medusa is described under the name of *Asenathia piscatoris*, g. et sp. nn., from the tidal creeks containing water of low but extremely variable salinity in the vicinity of Port Canning, in the Gangetic Delta. It is referred to the family Olindiadidæ of Mayer (order Trachymedusæ), and is regarded as not improbably the sexual generation of the hydroid *Annulella gemmata*, Ritchie.

In the part devoted to the Batrachians, Dr. Annandale deals chiefly with the Oriental frogs of the groups of *Rana tigrina*, *R. limnocharis*, and *R. Liebigii*, as well as with the species clustering round *R. Tytleri* and *R. erythraea*; also with various tadpoles from Japan, China, the Malay Peninsula, Burma, and Ceylon. The author's views on *R. tigrina* have since been a subject of discussion between him and Mr. Boulenger in the Records of the Indian Museum, and further differences of opinion between the two authorities will shortly appear in a monograph of the Oriental species of Rana to be published by the Indian Museum.

The two marine Sponges (*Reniera implexa*, Schmidt, and *Amorphinopsis excavans*, Carter, var. n. *Robinsonii*) discussed by Dr. Annandale were found growing on the wooden piers of a landing-stage at Port Weld in Perak, Malay Peninsula, and their chief ethological interest lies in the fact that they grew immediately below high-tide level, and were, therefore, exposed daily, for a considerable time to the air and to the heat of a tropical sun. Several new fresh-water Sponges from Japan, China, and the Malay Peninsula are described, and a list of the Spongillidæ of Asia, with synonyms, is appended.

Among the Mollusca the hybrid name Pseudovivipara for a new genus is a regrettable choice.

A paper in French is a revision of the fungi of the genus Nocandia, Toni and Trevisan, by Capt. Froilano de Mello and Dr. St. Antonio Fernandez, of the Portuguese India Bacteriological Service.

The Memoirs contain also a revision of the lizards of the genus Tachydromus, with two plates, by Mr. G. A. Boulenger, in which this genus is shown to be very closely connected with Lacerta, instead of occupying a quite isolated position in the family to which it belongs, as hitherto believed. Two new genera are proposed under the names of Platyplacopus and Apeltonotus.

In the Journal and Proceedings we have a paper by Baini Parshad on the seasonal conditions governing the pond-life in the Punjab. There are three papers on Mollusca: two by E. Vredenburg on the occurrence of *Cypraea nivosa* in the Mergui Archipelago, the only previously recorded habitat of this species being Mauritius, and of *Dolium variegatum* at Mascat and Karachi, a species hitherto regarded as special to the living fauna of Australia, but recorded from the Pliocene of Java; and one by Dr. Annandale and B. Parshad on the taxonomic position of the genus Camptoceras and of *Lithotis japonica*. W. H. Phelps describes the weaving habits of the spider *Cyrtophora citricola*, and Maude L. Cleghorn has experiments on the vitality and longevity of silkworm moths during the cold and rainy seasons in Bengal.

Botany is represented by four contributions: Notes on the flora of the Anaimaly Hills, by C. Fisher; on the pollination of flowers, by I. K. Burkill; on the Burmese sesamum varieties, their variation and growth, by A. McKerral; observations and experiments on the rust of *Launaea asplenifolia*, commonly known as Jangli Gobi, by Karm Chand Mehta; and on the constituents of the bark of *Hymenodactyon excelsum*, by C. L. Gibson and J. L. Simonsen.

Attainment of High Levels in the Atmosphere.

SCIENCE for March 19 has an article by Prof. Alexander McAdie, of Blue Hill Observatory, on "The Attainment of High Levels in the Atmosphere." A period of 135 years is dealt with, during which various methods and agencies have been employed for exploring the high levels of the atmosphere. Dr. John Jeffries crossed the English Channel in January, 1785, and attained a height of about 2012 metres, and in the following twenty years heights of more than 4000 metres were attained. In September, 1862, Glaisher and Coxwell reached a height of 11,200 metres. Three other noteworthy records by manned balloons are mentioned. Tissandier, Spinetti, and Sivel, acting for the French Academy, attained a height of 8530 metres in April, 1875; Dr. A. Berson reached 9600 metres in December, 1894; and Berson and Süring in 1901 attained a known elevation of 10,500 metres, and probably 10,800 metres, both men being unconscious at the higher level. Dealing with other than manned balloons, the extreme elevations noted are:—By kites, 7044 metres in 1907; by rigid dirigibles, 6200 metres in 1917; by sounding balloons, 37,000 metres in 1912; and by pilot balloons, height determined by theodolite, 39,000 metres. The aeroplane record has rapidly advanced. In 1909 Latham made 161 metres, and Drexel in 1910 made 1829 metres. Prior to 1914 the maximum height attained, according to Prof. McAdie, was 6000 metres by Perreyon in March, 1913. The war gave a great impetus to the development of the aeroplane, and since the war, in February, 1920, Major R. W. Schroeder, chief test pilot at Dayton, U.S.A., is stated to have attained 10,979 metres; in this ascent the oxygen-supply was exhausted. The 10-km. level is the bottom of the stratosphere or isothermal region, and the top of the troposphere or convectional region—an exceedingly important elevation to meteorologists. Schroeder's thermograph indicated a minimum temperature of −55° C., or 99° below the freezing point on the Fahrenheit scale.

In *Science* for April 9 Dr. J. G. Coffin, director of aeronautical research of the Curtiss Aeronautical and Motor Corporation, suggests that Prof. A. McAdie has sometimes accepted too readily unauthorised statements made in the Press as to altitudes reached. A criticism is made of expressing results without air-temperature correction, which is not only unsatisfactory, but also scientifically incorrect. The correction is the larger the colder the air encountered in the flight. It is pointed out that it is essential so far as possible for all concerned to work on the same un-

biased scientific basis. Dr. Coffin, to bring out the importance of the air-temperature correction, assumes two cases, both with identically perfect barographs, with no instrumental errors, one ascent in summer and the other in winter to an altitude that both read 8 in. of mercury as the minimum pressure. He assumes that in the summer case the average temperature of the air is 10° C., and in the winter −30° C., which values correspond closely to actually observed figures. The true altitudes of these are 33,475 ft. (10,203 m.) for the summer instance and 30,929 ft. (9427 m.) for the winter, although the altitude uncorrected for air temperature is 36,020 ft. (10,979 m.) for both. Dr. Coffin states that the flight made by Roland Rohlfs, the test pilot of the Curtiss Engineering Corporation, on September 18, 1919, attained an altitude of 34,910 ft. (10,640 m.), partially corrected, but uncorrected for the average temperature of the air column; the true altitude was 32,450 ft. (9890 m.) corrected for air temperature. The altitude attained by Major Schroeder, similarly corrected for temperature, is 30,751 ft. (9373 m.).

In *Science* of April 30, Prof. McAdie gives as approximate values, corrected for mean air column temperature, vapour pressure, gravity, altitude, and latitude: Rohlfs, 32,418 ft. (9880·5 m.), and Schroeder, 31,184 ft. (9505 m.).

The *Meteorological Magazine* for March, in an article "The Highest Aeroplane Ascent," mentions Major Schroeder's ascent on February 27 last referred to above, and expresses the hope that it will be authenticated in due course. The record of Berson and Süring, who, it is stated, reached 35,400 ft. (10,789 m.) in a balloon on July 31, 1901, is mentioned as being generally accepted as the greatest height hitherto attained by aeronauts. The article seems to throw some doubt on the lowest temperature observed in the ascent by Glaisher and Coxwell.

Physical Problems in Soil Cultivation.[1]

UP to the outbreak of the war the farmer could generally rely upon an adequate supply of cheap labour. He had no great necessity to introduce labour-saving machinery into the routine of the farm. But the increasing demands of the Army for men and the menace of the submarine campaign brought him face to face with the difficult problem of growing more food with a greatly reduced staff. In such conditions the employment of machinery was the only solution, and although at the time it was introduced mainly as a temporary measure, it is now quite evident that economic conditions will cause it to be retained permanently. During the war the rate of progress in the industry of agriculture was necessarily forced above the normal, and the urgent need at the present time is to take stock of the position, so that future developments may be guided along the right lines. In this connection the report of the Departmental Committee of the Ministry of Agriculture on Agricultural Machinery appears at an opportune moment. The report deals with "the further steps which should be taken to promote the development of agricultural machinery," and, so far as tillage implements are concerned, falls naturally into two sections, dealing with (1) fundamental research on the physical properties of soil as affected by cultivation operations, and (2) the application of the knowledge thus gained to the design of new implements and the improvement of old ones.

Taking the second section first, the Committee lays great stress on the fact that all development in the design of machinery has proceeded on empirical lines. "Although searching questions were addressed to several witnesses, we could not discover that any real attempt had been made in the past to determine the principles which underlie the design of the variety of implements in use in modern farming." As a result an enormous number of patterns of the same implement are made, one manufacturer alone having more than two hundred and fifty patterns of plough. The Committee considers that much of this overlapping and wasted effort will be avoided when the Ministry of Agriculture sets up its projected Research Institute in Agricultural Machinery.

The first section—research into the physical properties of soil—is regarded, rightly, as of primary importance. "Progress in research as regards tillage implements must depend largely upon the results of investigations into soil physics and the problem of tilth." It is clearly pointed out that this research must not be pursued with the immediate object of obtaining "practical" results. A sound theory of the interesting but complicated physical phenomena shown by soil must first be built up. Once this is achieved, the practical deductions will follow almost automatically. The very nature of this work precludes the possibility of forcing the pace, but it is suggested that, as the work has been in progress for some time at Rothamsted, it should be further developed by the appointment of additional scientific assistants.

If this were done it would be possible to pay more attention to those physical problems concerned with the soil tilth than is practicable at present. Tilth is related to the production of compound particles or aggregates in the soil, and to the factors causing plasticity, cohesion, etc. At the same time a study f the mechanical action of the plough could be started having as its aim the specification of the design of mould-board to meet different soil conditions. This is an unsurveyed field, and full of promise.

The report also deals with the educational and research work which should be carried out at the projected Research Institute in Agricultural Machinery, especially from the engineering point of view. It also advocates the appointment of an Advisory Committee, composed of representatives from the research institutions, implement-makers, and agriculturists, to co-ordinate the whole of the work.

In the present article attention has been confined mainly to the sections dealing with the physical questions involved. The report covers a much wider field. It is closely reasoned and convincing, and can be cordially recommended to all concerned in the industry of agriculture. B. A. KEEN.

The Anomaly of the Nickel Iron Alloys: Its Causes and its Applications.[1]

THE lecturer began by a reference to the work of John Hopkinson, and to his own early work on the perfecting of standards of length. His first experiments were on nickel, which had two great advantages over brass for metrological work, viz. its smaller coefficient of expansion and its greater freedom from corrosion. He would probably not have looked further but for the difficulty at the time of getting large bars of the material free from flaws. In investigating the

[1] Abstract of the Fourth Guthrie Lecture delivered before the Physical Society on April 23 by Dr. C. E. Guillaume.

ferro-nickel alloys, his first experiments were on their magnetic properties, as these were easier to investigate than the coefficients of expansion. Dr. Guillaume showed and explained curves representing the variation of magnetic properties, and of the coefficients a and β in the expansion equation $l=l_0(1+\alpha\theta+\beta\theta^2)$ for alloys in both the irreversible and reversible categories, and showed from the curves how it was possible to obtain alloys with any desired coefficient. The anomalous magnetic behaviour of some of the alloys was illustrated by demonstration experiments of the effect produced on the magnetic condition of bars of the materials by dipping in hot water or liquid air. The lecturer then dealt with the properties of ternary alloys containing iron, nickel, and a third element. Manganese alloys were those most extensively used. He exhibited a cardboard model of Guthrie's three-dimensional diagram for ternary alloys. The addition of the third element raised the minimum expansion. In the case of carbon and chromium the elastic constant is raised. The curve connecting Young's modulus with the percentage of nickel in ferro-nickel alloys also showed an anomaly in the same region as the expansion.

The chief weakness of the alloys from the point of view of the metrologist was instability. If a piece of invar was cooled from a high temperature in air at 100° C. its length reached a steady value in about 100 hours. If it was then cooled to 50° C. its length would increase to another steady value, reached in about 1000 hours or so. If it were then cooled to zero it would still further lengthen, a steady state not being reached for a very long time. If the temperature were then raised again to 100°, the length would diminish to its initial value for 100°. The total change of this character between 0° and 100° amounted to about 30 millionths of the length.

With increasing carbon content the instability very rapidly increased. It was possible from the amount of the instability to estimate the carbon to 1/100th per cent. Moreover, the curve connecting the instability and the carbon content passed through zero, showing that the instability was due to the carbon. It was therefore possible to get an invar of perfect stability.

Among the applications to which invar had been put, the lecturer instanced pendulum rods, leading in wires for electric lamps (an alloy being chosen from the curves so as to have the required coefficient of expansion), wire standards for base measurements in surveying, etc., and showed curves of the variation of height of the Eiffel Tower with temperature, as measured relatively to invar wires.

Another important application of these alloys was in chronometer construction. The temperature coefficient of the rate of a watch was due to variation of the elasticity of the hair-spring. This was corrected in the Graham compensation by a variation of angular momentum of the balance wheel, depending on the difference in expansion of two metals; but it was possible to choose for the spring a nickel steel having a temperature coefficient of elasticity nearly zero. If chosen to give the same rate at 0° and 30° there would be a secondary error of only 20 seconds per day at 15°. But a more important chronometric application was the correction of the secondary error of 2 seconds in Graham's compensation. This error, discovered by Dent in 1832, is due to the fact that the variation of elasticity of the hair-spring is not a linear function of the temperature, whereas the variation of angular momentum of the balance wheel is. If, however, for one component of the bimetallic compensator a nickel steel of negative β be chosen, it is possible to get a curve connecting the momentum with temperature which exactly compensates the elasticity variation over the whole range.

Reverting to the curves for Young's modulus, the lecturer predicted that an alloy would shortly be produced having a practically constant modulus over a range of 200° C.

Technical Education and Mind Training.

THE proceedings of the annual conference of the Association of Teachers in Technical Institutions, which was held in the Polytechnic, Regent Street, London, on Whit-Monday, were full of interest. The president, Mr. E. L. Rhead, of Manchester, gave a stimulating address, in the course of which he reviewed unfavourably the attitude of the Workers' Educational Association towards technical education as tending to narrow the workers' educational outlook, and as merely serving to create a human tool better calculated to promote the interests of employers and the sordid aims of industry. He claimed, on the contrary, that, rightly presented, technical education has in it all the elements of mind training and of a wide view of life and its problems. It may, in short, be, properly interpreted, constituted as the pivot of a liberal education. He deprecated the exclusive devotion of much of modern higher education to dead languages, dead history, and ancient philosophy, but that is surely to ignore a prime element in the evolution of mankind—the progress of man in his endeavour to search into and to solve the phenomena of Nature. Mr. Rhead went on to consider the status of the technical teacher as compared with that of the secondary-school teacher, and contended that the former should be at least as liberally considered as the latter, not only by reason of his long and arduous practical training in the processes of industry, but also in respect of the claims of industry itself upon his services. He urged the desirability of transfer from lower to higher schools at different periods in the course of the educational life of the capable pupil, and especially dwelt upon the value of the junior technical school, which he would in no wise desire to convert into a trades school, and pleaded that restrictions on their present aims and curricula should be removed. A far more liberal system of scholarships, including maintenance, should be established in co-operation with widely extended administrative educational areas, which should have regard not only to the pupils in day institutions, but also to the equally urgent requirements of the promising evening students, enabling them to devote themselves to whole-time study in their special vocation. There should likewise be an efficient representation of teachers on all education authorities, so that the present and future problems of technical education should be better considered. Resolutions were passed urging a large increase in salaries for the several grades of technical teachers; that all works continuation schools should ultimately be provided by the local education authorities and the present schools be open to inspection by the local and central authorities; and that a national Whitley council for teachers should be set up.

University and Educational Intelligence.

CAMBRIDGE.—Prof. J. T. Wilson, professor of anatomy in the University of Sydney, has been elected to the chair of anatomy rendered vacant by the death of Prof. A. Macalister.

We are informed by the secretary of the Cambridge Philosophical Society that the adjudicators of

the Hopkins prize have made the following awards:—For the period 1903–6 to Dr. W. Burnside, of Pembroke College, for investigations in mathematical science; for the period 1906–9 to Prof. G. H. Bryan, of Peterhouse, for investigations in mathematical physics, including aerodynamic stability; and for the period 1909–12 to Mr. C. T. R. Wilson, of Sidney Sussex College, for investigations in physics, including the paths of radio-active particles.

Dr. T. G. Adami, Vice-Chancellor of the University of Liverpool, has been elected to an honorary fellowship at Christ's College.

An offer of 30,000*l.* has been made to the University by the Committee of Council for Scientific and Industrial Research for the erection, equipment, and maintenance at Cambridge of a low-temperature station for research in biochemistry and biophysics. The proposal emanates from the Research Board of the Department charged with the co-ordination of researches related to the scientific problems arising out of the preservation and handling of food. It is desired to erect the new station close to the existing biological laboratories, where a large proportion of the researches initiated by the Board have been carried out. It is proposed to vest the management of the station in a committee of the Senate containing some members nominated by the Department of Scientific and Industrial Research. The director of the station would be appointed by the Lord President of the Council after consideration of a report by the committee.

LIVERPOOL.—A Congregation of the University was held in St. George's Hall on Friday, May 28, when honorary degrees were conferred. Mr. J. W. Alsop, Pro-Chancellor of the University and chairman of the Liverpool Education Committee; Sir Alfred Booth, chairman of the Cunard Steamship Line; Sir Alfred Dale, the former Vice-Chancellor of the University; Mr. John Rankin, a leading citizen and merchant of Liverpool; and Sir Michael Sadler, Vice-Chancellor of the University of Leeds, received the degree of Doctor of Laws. Sir Reginald Blomfield, a member of the Royal Academy and past-president of the Royal Institute of British Architects, and Mr. Frederick Powicke, professor of medieval history in the University of Manchester, received the degree of Doctor of Letters. The degree of Doctor of Science was conferred on Prof. F. G. Donnan, formerly professor of physical chemistry in the University, and now professor of chemistry in University College, London, and on Prof. W. A. Herdman, formerly Derby professor of natural history, and now professor of oceanography, in the University. Mr. Henry Martin, chairman of the St. Helens Higher Education Committee, and representative of the borough on the Court of the University, and Father Thomas J. Walshe, a distinguished scholar, and formerly chaplain and lecturer at the Notre Dame College in Liverpool, were given the degree of Master of Arts. Mr. Joseph Gibson, a leading engineer and president of the Liverpool Engineering Society, received the degree of Master of Engineering.

LONDON.—Two lectures, entitled "Emploi des métaux ammoniums en Chimie Organique" and "L'Œuvre Scientifique d'Henri Moissan," will be given at King's College, Strand, W.C., by Prof. P. Lebeau, professeur à l'Ecole Supérieure de Pharmacie, Université de Paris, at 5 p.m. on Monday, June 28, and Wednesday, June 30. The lectures, which will be delivered in French, are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket.

OXFORD.—The honorary degree of Doctor of Letters has been conferred on Dr. Temistocle Zammit, professor of chemistry in the University of Malta and curator of the Valetta Museum.

It was resolved by Convocation on June 1 to confer the title of professor on Dr. T. R. Merton, Balliol College, so long as he continues to hold the office of reader in spectroscopy.

ST. ANDREWS.—The Senatus Academicus will confer the following honorary degrees at the public graduation ceremonial to be held on July 2:—*LL.D.*: Sir Dugald Clerk; Dr. Léon Fréderícq, for nearly forty years professor of pathology in the University of Liége, Belgium; Mr. R. A. Herman, fellow and lecturer of Trinity College, Cambridge; Mr. W. J. Matheson, New York, U.S.A.; Dr. N. K. Smith, professor of logic and metaphysics in the University of Edinburgh; and Dr. N. Walker, his Majesty's Inspector of Anatomy for Scotland.

THE medal of honour of the University of Brussels was presented by the Vice-Chancellor on May 22 to Lord Dawson of Penn, Sir Leslie Mackenzie, and Prof. Sir William Smith.

PROF. E. F. NICHOLS has resigned the chair of physics held by him at Yale University to take up the post of director of pure science in the Nela Research Laboratories of the National Lamp Works of the General Electric Co. at Cleveland, Ohio.

IN connection with the London County Council's lectures for teachers on recent developments in science, a lecture on "The World-Problem of Nitrogen" will be given by Prof. F. G. Donnan at University College, Gower Street, W.C.1, on Monday, [illegible] 7, at 6 p.m. The chair will be taken by Lord Moulton.

A PUBLIC meeting in support of the claim of the Imperial College of Science and Technology for degree-conferring power and university status will be held at the Central Hall, Westminster, to-morrow, June 4, at 5 p.m. Lord Morris will preside, and will be supported by Sir Arthur Acland, Bart., Sir Alfred Keogh, Col. Sir Pierre van Ryneveld, Mr. H. G. Wells, Mr. J. A. Spender, and others.

THE foundation-stone of the new wing of the London School of Economics was laid by the King on Saturday last, May 29. His Majesty was accompanied by the Queen and Princess Mary, and the Royal party was received by Dr. Russell Wells, Vice-Chancellor of the University of London. In an address Dr. Wells referred to the meeting held at the Mansion House in 1918, when it was determined to institute London degrees in commerce, and to collect funds in order to found and endow in the University what it is hoped would ultimately become the greatest school of commerce in the world. As a result of the response to the appeal of the University by the bankers, shippers, and merchants of London, and the substantial contribution of Sir Ernest Cassel, through the Cassel Trustees, the sum of more than 300,000*l.* was obtained towards the founding and endowing of the scheme for commercial education. In the course of his reply the King said:—"I am fully sensible of the patriotic work which has been accomplished by the universities during the war, of their instinctive and immediate response to the call of duty, of their heavy burden of sorrow and loss, of their varied and brilliant contributions to the science of modern warfare, and of the extent to which their normal activities have been suspended or deflected by five years of national peril. It is for this reason the more gratifying to me to note that the University of London, which has grudged nothing of its youth and valour to our armies in the field, has been planning the development of

new spheres of usefulness in the furtherance of the fruitful arts of peace. Three centuries ago Francis Bacon censured the universities of his own age as the homes of ignorant dogma and sterile disputation. The bad and narrow tradition which was then attacked has long since disappeared, and the circle of academic studies has been steadily enlarged by the pressure of scientific ideas and of practical needs without injury to the claims of a broad and humane education. When estate management, horticulture, and commerce are included in the curriculum, a university can no longer be described as a place in which nothing useful is taught. It is right and fitting that the new faculty of commerce should be linked to the London School of Economics, which has for many years enjoyed the reputation of being one of the principal centres of economic inquiry in my Empire, and I regard it as no less appropriate that a university situated at the very heart of our commercial system should now resolve to turn the dispassionate and illuminating eye of science upon the facts and principles of commercial life."

Societies and Academies.

LONDON.

Royal Society, May 20.—Sir J. J. Thomson, president, in the chair.—Prof. J. N. **Collie**: Some notes on krypton and xenon. In the paper the measurements of a considerable number of new spectroscopic lines at the red end of the spectrum are given; also a curious property of xenon has been noted. In tubes containing xenon, when a strong current from an induction coil is passed, much splashing of the electrodes occurs, and the xenon disappears as a gas. What becomes of the xenon is not clear, as it does not seem to be liberated again, either by strongly heating the metallic splash or by dissolving up the splash in suitable solvents.—Sih **Ling Ting**: Experiments on electron emission from hot bodies. Experiments on the electron currents from a platinum disc in a uniform field made by Prof. Richardson in 1907–9 showed that under the conditions of these experiments the distribution of velocity among the emitted electrons was very close to the requirements of Maxwell's law for a gas of equal molecular weight and temperature, but it was noted at the time that rough tests made on the liquid alloy of sodium and potassium, on platinum coated with lime, and on platinum saturated with hydrogen indicated an exceptional behaviour. The further investigation of these substances was postponed owing to technical difficulties and to the pressure of other problems. In 1914 Schottky investigated the electrons emitted from tungsten and carbon, and found a distribution of energy in close accordance with Maxwell's law, except that the mean energy varied between 2 per cent. and 25 per cent. in excess of that calculated from the filament temperatures. Errors in the estimation of these temperatures and in other directions might, however, have accounted for these discrepancies. The present experiments show that deviations from Maxwell's law, if not general, are at any rate quite common. With tungsten and platinum in a well-exhausted enclosure a common distribution is one which satisfies the requirements of Maxwell's law, except that the average electron energy is in excess of (frequently about twice as great as) that corresponding to the temperature of the source. Other cases have been recorded in which the velocity distribution has a different functional form.—L. **Silberstein**: The aspherical nucleus theory applied to the Balmer series of hydrogen. The general formulæ for spectrum emission by atomic systems containing an aspherical nucleus, given by the author in a previous paper (*Phil. Mag.*, vol. xxxix., p. 76), are now applied to hydrogen atoms the nuclei of which are treated as axially symmetrical charged distributions. The asphericity and the value of the Rydberg factor are determined from Mr. Curtis's observations of Hα up to Hγ. The series formula thus resulting (and containing but two constants) is shown to agree well with the six observations. The value of the asphericity coefficient is then used to determine the fine structure of the members or groups of the Balmer series, more especially of the groups Hα and Hβ, which are discussed in some detail.—T. E. **Stanton**, Miss D. **Marshall**, and Mrs. C. N. **Bryant**: The conditions at the boundary of a fluid in turbulent motion. Observations were made on air flowing through long pipes of circular cross-section at mean rates of flow covering as wide a range as possible below and above the critical speed. Dimensions of pipes used were 0·269, 0·714, and 12·7 cm. in diameter. Range in experimental conditions varied from $vd/\nu=460$ to $vd/\nu=325{,}000$, where v is mean speed of flow, d diameter of pipe, and ν kinematic viscosity of air. Estimation of velocity of fluid in neighbourhood of boundary was made from observations of difference in pressure existing in a small Pitot tube facing the direction of flow, and that in a hole in the wall of the pipe. The Pitot was of rectangular section, external dimensions at orifice being $0{\cdot}1\times0{\cdot}8$ mm. and internal dimensions $0{\cdot}05\times0{\cdot}75$ mm. By this means observations could be made up to a distance of 0·05 mm. from the wall. For distances less than this, by a special device the wall of the Pitot nearest the wall of the pipe was cut away and its place taken by the wall of the pipe. By this means observations could be taken at a distance of 0·01 mm. from the walls. From a comparison of the curves of velocity distribution near the boundary, obtained from observations with the Pitot and the composite tube, it was found that in the case of the former the interference with the flow near the orifice by side of tube adjacent to boundary was considerable. Velocity curves obtained from the composite tube, when further corrected for interference, were found to tend to a definite slope at boundary, which was identical with that which would exist in a layer of fluid in laminar motion and having the same surface friction as that actually measured.

Linnean Society, May 6.—Dr. A. Smith Woodward, president, in the chair.—Dr. G. P. **Bidder**: Sponges. (1) The fragrance of calcinean sponges. Clathrinidæ have a noticeable aromatic scent, probably due to the excretory granules which give their bright colours. These granules especially surround the pores. May this be to attract the spermatozoa? The author has not seen the fine-lashed spermatozoa of Poléjaeff, but in Sycon has observed a stiff-tailed organism—possibly the result of curious gregarine-like objects produced in cells resembling gonocytes. (2) *Syncrypta spongiarum* (wrongly assigned to Pandorina in his MS.) the author gives as a name to the "alga" abovementioned. He suggests that it is a dangerous parasite, against which *Grantia compressa* has a successful phagocytosis, but that certain other sponges are hosts for its Palmella stage. (3) Notes on the physiology of sponges. (*a*) Cercids, proposed as a name for the "minute wandering cells." (*b*) Cessation of the current in sponges. (*c*) Differences between Calcinea and Calcaronea in their porocytal granules and odour. (*d*) The excreta of collar-cells are gelatinous globules containing dark particles. Probably Dendy is right in comparing these to the "spermatozoön-heads" of Poléjaeff, which may be the ultimate residue of victorious

phagocytosis. (*e*) Origin of sponges. Archæocytes may have been differentiated into external excretory cells and internal reproductive cells; the former engulfed cercids, but only to pass them on to the latter. By abbreviation of this process the excretory cells may have become self-perforating porocytes, which were then adapted to supply water to flagellate cells in the centre of a Protospongia-like colony, thus converting it into an elementary Olynthus.

Royal Meteorological Society, May 19.—Mr. R. H. Hooker, president, in the chair.—Dr. Griffith **Taylor**: Agricultural climatology of Australia. The author, after indicating briefly the diversity of climates in Australia, pointed out the extreme importance of the rainfall, more so than in most other countries, as the controlling factor in the settlement of the country; also that the season at which rain falls and the certainty of its occurrence (its "reliability") were as important as the total amount. The greater proportion of the wheat-lands lay in regions receiving less than 20 in. of rain per annum, while the crop can be grown with as little as 7 in. if it falls at the right time. Sugar-cane is confined to the eastern coast, where the rainfall exceeds 40 in. and the temperature 68° F. The hay crop is also important, and in dry seasons when the grain fails includes a large bulk of cereals. Ninety per cent. of the sheep are in the south-eastern third of the continent; a rainfall of at least 10 in. and a temperature below 77° are required for them. Cattle are reared more in the north-east. The great variability of the rainfall frequency results in serious droughts and consequent failure of the cereal crops and reduction of flocks and herds; but it is hoped that these recurrent losses will become less serious in time with the progress of irrigation, though Dr. Taylor is not sanguine that irrigation will open up to settlement the enormous areas that seem to be anticipated by some writers.—J. E. **Clark** and H. B. **Adames**: Report on the phenological observations for the year 1919. The dominant factors in 1919 were the excessive wetness until April and drought in May and early June, lasting or reappearing until October or later. The abnormally warm December of 1918 was followed by four months universally cold, closing with heavy snow in the last week of April. Then hot summer weather in May and early June preceded a detrimental six weeks or more of abnormal cold. Cold recurred after August, culminating in a November deficiency beyond most records. In consequence, summer-growing garden crops (such as celery and cauliflower) were poor and most field crops short, though fairly good, especially potatoes. Of tree-fruits only plums and apples cropped heavily, the latter ripening and colouring to a degree rarely known, and excelled only by the wonderful autumn tints—both, no doubt, due to the dry and sunny autumn. As to the tables, the four earliest flowers were nine days late, but the effect of May was to make the last four decidedly early. The early migrants were late, especially the nightingale. The 1919 isophenes were seven days further south than in 1918. The number of observers has been further reduced from war effects, barely exceeding 100, but 1920 prospects are such that at least a 100 per cent. increase is probable. The areas worst represented are Wales, the south-west of Ireland, and the north-west of Scotland. Observers from these parts will be most welcome.

MANCHESTER.

Literary and Philosophical Society, April 20.—Sir Henry A. Miers, president, in the chair.—W. J. **Perry**: The origin of warlike States. In previous papers the author has put forward the theory that, speaking generally, warlike States are those with an hereditary military aristocracy. In an examination of the ruling groups of the chief historical peoples, Teutonic, Turko-Tartar, Semitic, the facts suggest their beginning as small groups claiming divine descent. These groups seem to be of "matriarchal" origin, and the chief religious feature was the cult of the Great Mother. Just after the new groups of rulers had been formed, the institutions became patrilineal, and the Great Mother was replaced by gods. Study of the practice of heraldry verifies the author's theory. This law of "dynastic continuity," if true, leads to the conclusion that all ruling classes in the world are derived from one original group; and this result harmonises with Prof. Elliot Smith's claim that all civilisation originated in the Ægypto-Sumerian region.

PARIS.

Academy of Sciences, May 10.—M. Henri Deslandres in the chair.—C. **Guichard**: Networks and congruences conjugated with respect to a linear complex.—Prof. W. H. Perkin was elected a correspondant for the section of chemistry in succession to M. Ciamician, elected foreign associate.—P. **Boutroux**: A family of multiform functions defined by differential equations of the first order.—M. **Janet**: Systems of equations of derived partials.—G. **Cerf**: The analysis of anti-symmetrical tensors and the symbolic forms of differentials.—C. **Camichel**: Application of the principle of images to water-vessels.—Th. **De Donder** and H. **Vanderlinden**: New fundamental equations in generalised co-ordinates.—J. **Carvallo**: A new universal method of measuring and compensating instrumental astigmatism.—A. **Kling** and A. **Lassieur**: The separation of tin and antimony. The estimation of tin by cupferron. The antimony is separated as sulphide in hydrofluoric acid solution, boric acid added to the filtrate to convert the hydrofluoric acid into fluoboric acid, and the tin precipitated by cupferron.—F. **Bourion** and Ch. **Courtois**: A method of modified enrichment in the analysis of commercial chlorobenzenes. Some refinements on a method described in an earlier communication.—G. **Tanret**: Pelletierine and methylpelletierine. Hess and Eichel were unable to isolate the optically active alkaloid pelletierine, and could only obtain the inactive isomer *iso*pelletierine; hence they propose that the name *iso*pelletierine should be dropped. In the present paper experimental confirmation of the work of Ch. Tanret on the optically active alkaloid is given.—A. **Mailhe**: A new preparation of amines by catalysis. The hydrazines obtained from acetaldehyde, *iso*butyraldehyde, and from valeraldehyde heated with hydrogen in presence of nickel give mixtures of primary, secondary, and tertiary amines.—A. **Guébhard**: The planet Mars and "igneous sedimentation."—R. **Souèges**: The embryogeny of the Solanaceæ. Development of the embryo in Nicotiana. Nine diagrams are given showing the principal steps in the development of the embryo. The statement of Hanstein, that the embryo of Nicotiana [illegible] according to laws comparable with those observed in Capsella, is shown to be inexact.—A. **Chevalier**: Researches on the Amygdalaceæ and the apple-trees of the cooler parts of Indo-China and of the south of China.—A. **Piedallu**, P. **Malvezin**, and L. **Grandchamp**: The treatment of the blue *casse* of wines. Oxygen gas in very minute bubbles, produced by forcing the gas under pressure through the walls of a porous porcelain filter, can rapidly convert ferrous salts into ferric salts. The wines clarify readily, and are reduced to a normal state.—L. **Bertin**: Remarks on the buccal and feeding apparatus in some Coleoptera.—P. **Courmont** and A. **Rochaix**: The action of the microbial flora of sewage effluents purified by the activated-sludge method on carbohydrates.

17.—M. Henri Deslandres in the chair.—G. **Bigourdan**: Lechevalier at the Observatory of Saint-Geneviève. The co-ordinates of this observatory.—M. **Hamy**: A particular case of diffraction of the images of circular stars of large diameter.—L. E. Dickson was elected a correspondant for the section of geometry in succession to M. Cosserat, elected non-resident member.—P. **Humbert**: The general solution of the system which satisfies the function W (x, y).—N. **Pipping**: A criterion for real algebraical numbers, based on a direct generalisation of Euclid's algorithm.—J. **Drach**: The spiral compensator and new problems of the mechanics of regulation. The spiral compensator of M. Guillaume, obtained by addition of a third or a fourth metal to an iron-nickel alloy, is the first example of a solid the elasticity of which increases with the temperature. The application of this to the control of chronometer balance-springs is discussed, and reasons are given for supposing that the chronometer will equal the astronomical clock in accuracy.—Ch. **Frémont**: The genesis of cracks in certain axles.—P. **Morin**: The study of flow over a weir with the aid of chronophotography.—M. **Battestini**: The optimum magnification of a telescope. The magnification of a reading telescope should be reduced proportionally to the square root of the illumination of the field.—L. **Thielemans**: Calculations and diagrams of lines carrying energy to great distances.—G. **Bruhat**: The properties of fluids in the neighbourhood of the critical point and the characteristic equations.—J. **Villey**: The discussion of Michelson's experiment.—C. **Zenghelis** and B. **Papaconstantinos**: The acceleration of the decomposition of hydrogen peroxide by colloidal rhodium. From measurements of the velocity constants the reaction is shown to be unimolecular. If the solution of colloidal rhodium is treated with a current of hydrogen or carbon monoxide the reaction is accelerated.—F. **Bourion**: The impurities of the benzene extracted from commercial chlorobenzenes. Normal hexane and heptane have been isolated, and also chloroform, from benzene extracted from commercial chlorobenzene.—C. **Matignon** and Mlle. **Marchal**: The prolonged action of carbon dioxide on silicates and quartz. Six minerals and glass were submitted to the action of a solution of carbon dioxide in water under a pressure of 10 atmospheres for a period of ten years and three months. The quantities of silica in solution were estimated, and the minerals after this exposure examined microscopically for evidence of attack. Quartz, wollastonite, mica, talc, dioptase, and asbestos showed signs of corrosion. With glass the corrosion was scarcely perceptible.—J. **Bougault** and J. **Perrier**: The action of hydrocyanic acid on glucose: Kiliani's reaction. In solutions faintly acid, even as weak as hundredth normal, the combination between hydrocyanic acid and glucose does not take place, and this would also appear to be the case in neutral solution. A slight alkalinity, even as small as that derived from the glass containing vessel, determines the reaction, which is therefore probably between glucose and alkaline cyanide. The reaction between potassium cyanide and glucose was quantitatively studied, and proved to be bimolecular.—L. **Cayeux**: The Hettangian iron minerals of Burgundy. The iron mineral at Beauregard is not oolitic, but the whole of the oxide of iron is a substitution product for calcium carbonate.—Ph. **Négris**: The alternatives of the Glacial and inter-Glacial epochs during the Quaternary period.—G. **Ferronnière**: An Eifel layer of the Basse-Loire synclinal.—A. **Boutaric**: The intensity of nocturnal radiation at high altitudes.—E. **Rothé**: A new electrical anemometer. For observations of wind velocities at high altitudes the anemometer is carried in a small captive balloon, and the anemometer vane serves as an interrupter, which at each contact puts in action a small electrical oscillator. At the base of the cable holding the balloon is a small receiving apparatus for detecting wireless signals. The indications of several instruments fixed at different heights up the cable can be received simultaneously.—G. **André**: The exosmosis of the acid principles and sugars of the orange.—P. **Bugnon**: The structure of certain fibro-vascular bundles in the stems of the Gramineæ.—H. **Piéron**: The variation of the energy as a function of the time of stimulation for peripheral vision.—A. **Mayer**, H. **Magne**, and L. **Plantefol**: The reflexes provoked by irritation of the respiratory passages. Action of the general exchanges of the organism. The irritation of the terminations of the trigeminal nerve in certain mammals has the effect of causing, for more than half an hour, a reflex diminution of the general exchanges of the organism. These may be lowered to a value very small compared with the normal.—A. **Desgrez** and H. **Bierry**: Nitrogen equilibrium and lack of vitamines.—R. **Hovasse**: The number of chromosomes in parthenogenetic tadpoles.—M. **Delage**: Remarks on the preceding communication.—J. **Legendre**: The food *régime* of *Carassius auratus* in Madagascar.

Naval Education.

THE discussion in the House of Commons on May 17 on the vote for educational services in the Navy Estimates raised several points of interest. We note a general wish to open more widely the door from the lower deck to the commissioned ranks. At present the most promising of the younger seamen can rise, through the intermediate rank of mate, to that of lieutenant at an age which does not shut them out from further promotion. Several members expressed a hope that it might be possible to promote ships' boys to the rank of midshipman. The First Lord is reported in the *Times* to have replied that the Admiralty "could do no more than place at the disposal of these lads the very excellent educational facilities now open to the lower deck, but would approach the question with a steadfast determination to remove every possible obstacle which appeared likely to prevent these lads attaining their object."

Lieutenants whose training at Dartmouth was curtailed during the war are now sent to Cambridge for a supplementary course. The special situation which led to this arrangement will pass away, but it is intended to make the Cambridge course a permanent feature of the education of 25 per cent. of the officers, if accommodation at the colleges permits. The young naval officer sees little outside his sea life—a life astonishingly wide in some ways, and equally narrow in others—and intercourse at Cambridge with other young men will broaden his ideas.

Osborne is to be closed in May, 1921. Cadets will go straight to Dartmouth at the age of thirteen and a half and stay there until the age of seventeen; then to sea. The First Lord spoke with regret of the necessity of closing Osborne, which has done good work in education; but the total number of cadets under training on shore will be not more than 440, as against 1000 before the war, and it would be incompatible with economy to retain a special college for the younger cadets with these reduced numbers. If one of the colleges is to go, clearly it must be Osborne, where the buildings are for the most part temporary structures, whereas Dartmouth is a sumptuous edifice of brick and stone, which will house the whole number.

In an explanatory memorandum issued with the Estimates it was stated that changes were to be made in the curriculum. These are of some importance, and cannot be properly appreciated without some knowledge of the history of the matter. Lord Selborne's scheme of training (1903) provided for the common entry of executive and engineer officers; all were to enter Osborne together, and to receive an identical training between the ages of thirteen and twenty-two. Having reached the rank of lieutenant at twenty-two, they were to select the branch to which they would afterwards devote themselves—gunnery, torpedo, navigation, engineering, or non-specialist. The most difficult problem was the training of the engineer. Up to twenty-two he would not have a more intensive engineering training than all other officers; from twenty-two he would devote himself entirely to engineering. Many consequences followed this decision; in particular, it was necessary to assign one-third or one-fourth of the instructional time from thirteen to twenty-two to engineering. The engineer officers (Lieutenants E) trained under these conditions are understood to be doing well, but the time left for general education at the colleges was restricted rather severely, and in the case of the executive officers this restriction seemed to be a mistake. How could this defect be remedied without impairing the technical training of the engineers? It emerges from the Admiralty memorandum that the following solution is to be tried. The engineering time at the colleges (thirteen and a half to seventeen) is to be greatly reduced, and the time saved to be spent in enriching the cadets' literary education. At the same time, the age of specialisation for engineers is to be lowered from twenty-two to eighteen.

It may be surmised that this increased sense of the value of early general education is not unconnected with comparisons made during the war between the midshipmen from Dartmouth and the "direct entry" midshipmen who entered from the ordinary schools of the country at

eighteen. The latter are understood to have justified their selection, and in the opinion of some officers were superior to the Dartmouth entry in certain respects. One reason for such a superiority, if it really exists, is so dominant that it is unnecessary to look further. The "direct entry" midshipmen finished their education uninterruptedly at the schools, carrying it on to the age of seventeen and a half or eighteen. The Dartmouth boys were sent to sea prematurely, many of them at fifteen and a half instead of at the normal age of seventeen. They were an unfinished product, and from an educational point of view it is satisfactory that this curtailment of general education should have had such a marked effect on efficiency at sea that many officers were led to make the comparison referred to above. For the reason stated, the comparison could not be fair, but it was made, and it set naval officers thinking.

Not so many years ago it was axiomatic in the Navy that sailors "must be caught young," at a tender age, and not when they leave a public school. It is no longer axiomatic. There is acute division of opinion among naval officers on this subject. So long as it was considered necessary that cadets of thirteen and upwards should spend one-quarter of their time in engineering, it was impossible to look to the schools of the country for the secondary education of naval officers. But the amount of engineering to be learnt in future between thirteen and eighteen is not more than could be taught at any well-equipped school. The problem is therefore open whether the Navy is to continue to undertake the secondary education of its officers, or to leave the task to the schools. The First Lord stated that the Admiralty had no intention of abolishing Dartmouth as well as Osborne, and referred to advantages which could be conferred at a naval college on the sons of needy naval officers. But he believed the public-school system of entry—the "direct entry" system—to be thoroughly good, and fifteen midshipmen are to be entered annually from the schools, as against 120 through Dartmouth.

In favour of maintaining a naval college for cadets is urged the advantage of early acquaintance with Navy habits and discipline, the doubt whether the numbers required—very moderate numbers now—could be recruited at the age of eighteen, the present overcrowded state of the public schools, and the special consideration referred to by Mr. Long in his speech. In favour of relying entirely on the schools of the co[illegible]try, many nav[illegible]ers argue that a bo[illegible]ok is narrowed [illegible] from [illegible] an age with none but [illegible]sion; that there is nothing at a [illegible]llege which quite makes up for the influence exerted by a good public-school house master; that "direct entry" saves heavy expense to the Exchequer; and that it is more difficult to select at the age of thirteen than at eighteen.

The debate, therefore, has begun, and the outcome will probably be determined by the eventual balance of opinion within the Service.

The Ultimate Data of Physics.

An Enquiry concerning the Principles of Natural Knowledge. By Prof. A. N. Whitehead. Pp. xii + 200. (Cambridge: At the University Press, 1919.) Price 12s. 6d. net.

PHYSICISTS and philosophers can unite unreservedly in an expression of gratitude to the author of this most acute and original work. At the present time, when it is generally recognised that the ultimate concepts of physics require reinterpretation, it is a piece of great good fortune that the task should be undertaken by a thinker who is not only one of the foremost of living mathematicians, but also a metaphysician who sees clearly the wider issues that are involved.

As Prof. Whitehead remarks, the incoherent character of the traditional concepts of speculative physics has long been a commonplace in philosophical treatments of the subject. Instantaneous moments, geometrical points, unextended particles, etc.—these may be convenient, and even essential, notions for the purposes of physical investigation, but, if taken to indicate existent entities, are quite unworkable notions. On such a basis the fact, for example, of change in all its forms would become not merely incomprehensible, but contradictory; to be intelligible, "change must," as Lotze put it, "find its way into the inside of being." In other words, change as mere sequence, as mere alternation, is an impossible thought. Change means, if it means anything, continuous modification in that which preserves a certain identity or unity, without, however, implying that the latter ingredient is something separate from the former. Nothing which is characteristic of force, velocity, energy, and life can exhibit itself at a durationless instant. The slightest functioning of a living organism obviously takes time, but so also does that of a molecule of iron. In Aristotelian language, it may be asserted that the true nature of any real existent

is never that which can be present all at once, but that which is being realised in the totality of phases through which the existent thing in question passes.

Since the appearance of his well-known paper in the *Phil. Trans.* of 1906, Prof. Whitehead has been wrestling with the problem which considerations such as these occasion, and he has now worked out a positive theory of the structure and diversification of Nature, upon the basis of which a rationale can be furnished of the concepts indispensable in mathematical physics. The aim, then, of the present volume may be said to be twofold: (1) To determine by analysis of what is offered in perceptual experience the ultimate data of science and their relations; and (2) to show how the concepts of mathematical physics and their relations can be exhibited as functions of the former.

Nature, so I understand Prof. Whitehead to mean, must be regarded as in its totality a continuous stream of process, of becoming, of creative advance. Within this whole there call to be distinguished two essentially different, yet intimately connected, types of entity—events and objects. Employing, again, Aristotelian phraseology (and in many ways Prof. Whitehead's scheme of Nature more nearly resembles the Aristotelian scheme than any other), events constitute the ὕλη and objects the εἶδος of things. Events are either durations or bits of a duration, and a "duration" is a "slab of Nature," limited temporally, but unlimited spatially, which is contemporaneous with the specious present of any percipient. The fundamental relation of events is that of extending over each other, and this relation of "extending over" is the common root from which both temporal extension and spatial extension take their origin. Strictly speaking, events themselves do not change; they pass into other events, and in passing become parts of larger events, the passage of events being extension in the making. Moreover, some of the events that are parts of durations (*e.g.* a specific state of perceiving) have a relation of cogredience to a certain duration—that is to say, they are temporally coextensive with it, and they occupy in it a fixed spatial position. Furthermore, events are the "situations" of objects—an object is located in an event as that event's characteristic or quality. Like Aristotle's εἶδος, an object is permanent. When we speak of its change we really mean its diverse relationships to diverse events. Precisely the same object can characterise two or more events. The continuity of Nature is to be found in events. The atomic properties of Nature reside in objects. There is, in short, a structure of events (an "ether of events" rather than a material ether), and it provides the framework of the externality of Nature within which objects have their subsistence. This structure is capable of being analysed in a number of different ways, and by adopting different modes of analysis we human beings can get at the various kinds of events which are "situations" of different types of objects. The more important of these types are: (*a*) Sense-objects—*e.g.* definite sense-data; (*b*) perceptual objects—*i.e.* the so-called "things" of ordinary experience; and (*c*) scientific objects—*i.e.* the characteristics (electrons, etc.) of events as active conditions. With the exception of those perceptual objects that are delusive, all these types of objects are equally real. Their *esse* is neither *percipi* nor *intellegi*.

For the mathematician the detailed working out of the way in which the concepts of point, instant, particle, etc., may be brought into connection with the data just indicated will probably be the most valuable part of the treatise; but I must be content to record that it is accomplished through persistent applications of what is named the method of extensive abstraction. This method, it is explained, is that which in its own sphere (the sphere, namely, of geometry and mechanics) follows the procedure of the differential calculus in the region of numerical calculation. It converts a process of approximation into an instrument of exact thought. By its means, as Dr. Broad has neatly expressed it, the *convenience* in these concepts is retained, while the *fiction* in them is eliminated.

With the main principles of Prof. Whitehead's philosophy, yielding, as they do, a view of Nature strikingly antithetical to that of the logical atomism developed by Mr. Russell, the present reviewer is in close agreement. One would like to press, indeed, for a fuller elaboration of the notions of "duration," "event," and "passage of events" than is here attempted. For one has an uneasy feeling that a host of embarrassing problems lies concealed in those notions. And then, again, one is uncertain about the mode in which events are supposed to be apprehended. While objects are recognised, events, we are told, are "lived through," by which apparently we are to understand that not only the "percipient event" (*i.e.* the actual phase of experiencing), but also the whole duration with which it is cogredient is "lived through." Yet obviously it is not meant that the countless other events, some cogredient and others not with that duration, are in like manner "lived through," and one fails to see how there can be any unique process of appre-

hending *them*. Once more, one would be prepared to question whether "sense-objects" are primary as compared with "perceptual objects"—primary, that is, in the sense that the recognition of them is precedent to the recognition of the latter. But the last two of these criticisms turn upon matters of detail, and the first amounts to a large order. When all this is said, the fact remains that in the volume before us we have a really great effort of constructive thinking. Prof. Whitehead modestly observes that his book "raises more difficulties than it professes to settle." He adds, however, with true insight, that "to settle the right sort of difficulties and to raise the right sort of ulterior questions" is to accomplish one step further into Nature's background of mystery.

G. DAWES HICKS.

Life and Letters of Silvanus P. Thompson.

Silvanus Phillips Thompson, D.Sc., LL.D., F.R.S. His Life and Letters. By J. S. and H. G. Thompson. Pp. ix+372. (London: T. Fisher Unwin, Ltd., 1920.) Price 1*l*. 1*s*. net.

IF this biography of the late Silvanus P. Thompson, written by his wife and daughter, is perhaps a little wanting in the detached criticism that could have come only from someone outside the family circle, it gives, from an inside and intimate point of view, a good idea of the extent to which its subject appreciated the gospel of work, and how he applied himself, with all his might, to the many varied and interesting things that he found for his hand to do.

The book commences with some account of Thompson's Quaker ancestry and his early training at Bootham School, York, and at the Quaker Training College at Pontefract. Later, Thompson returned to Bootham School as a junior master, and it was during this time that he made the first of many visits to the Continent, which he evidently greatly enjoyed, and which did so much both to widen his outlook and to increase the large number of his foreign scientific friends. His appointment as lecturer on physics at Bristol was the first step in his scientific career, and at Bristol he remained, lecturing to his students and also, farther afield, to various popular scientific societies, attending meetings of the British Association, and making many contributions to electrical science, until his appointment as principal of the Technical College at Finsbury, which was the chief scene of his labours for the remaining thirty-one years of his life.

Essentially fitted by Nature to be a teacher and an exponent, and endowed with habits of industry to a rare degree, Thompson touched little that he did not to some extent adorn, and while in an age of specialism, by reason, no doubt, of a certain diffuseness of his interests, he never concentrated sufficiently upon any one branch of scientific research for his name to be associated with any first-class discovery, there can be no doubt as to the considerable extent that, by his books, his lectures, and his teaching, he forwarded the progress of science, and especially of its applications, during many years of activity. We learn that with remarkable industry he was the author of no fewer than seventeen published books, besides eleven others that were privately printed, while his addresses and communications to societies during the forty years from 1876 down to the date of his death number 177. Electricity, magnetism, optics, and acoustics were his principal subjects, but he also wrote on educational, religious, and other questions, while not least amongst his writings will be considered his biographies of Kelvin and of Faraday, and his notes on the lives of Peter Peregrinus, the soldier of fortune who penned his treatise on the magnet as early as the thirteenth century; Gilbert, the Elizabethan physician, who also wrote on the magnet; Sturgeon, the inventor of the electro-magnet; and Phillip Reis, whose apparatus, if it was not sufficiently developed to become of practical utility, was, at any rate, the forerunner of that wonderful instrument of sublime simplicity, the speaking telephone of Alexander Graham Bell.

Thompson, too, at an early stage in his career, tried his hand at practical telephonic invention, but his ingenious valve telephone was held by the courts to be an infringement of the Bell-Edison patents, and its sale was prohibited. Only on one other occasion do we find him coming out as an inventor, this time in connection with submarine cables for telephonic and high-speed telegraphic purposes. Here, though his particular arrangement of inductive leaks never came into practical use, it led the way to the Pupin loading coil, with which much has been accomplished.

It is recorded that, as a young man, Thompson cared little for games; but that this did not mean any lack of appreciation of the lighter aspects of life is evidenced by the vein of humour in many of his letters, and by the prominent part he took in connection with the "Red Lion" dinners of the British Association, and with such clubs as the Gilbert Club and the Sette of Odd Volumes, in which latter he bore the appellation of Brother Magnetizer. He also had many hobbies, some of which were not scientific, as, for instance, music, poetry, and painting, while as an artist himself he held no mean place, and occasionally exhibited

at the Royal Academy. An exhibition of his sketches held after his death comprised more than a hundred separate pictures.

Himself probably the most eloquent of scientific exponents since Tyndall, it is interesting to learn that Thompson fully realised, as has many another, the difficulties pertaining to the giving of a Royal Institution discourse, where it is not unusual for some few of the audience to know quite as much as, if not more than, the lecturer, while the majority can fully understand but little of what they hear. Of interest also is the account of the slender beginnings of his library, which his proclivities as a collector and as a learned bibliophile led him to accumulate, until, enriched as it was by many ancient works and a whole host of rare pamphlets, it developed into one of the most complete and valuable existing collections of electrical publications.

It is satisfactory to know that the skill and labour expended in making this collection will not be thrown away, as the whole library is to be preserved intact at the Institution of Electrical Engineers, where it will form a worthy monument to Thompson's industry and discernment.

A. A. Campbell Swinton.

Academic Research and Industrial Application.

The Chemistry and Technology of the Diazo-Compounds. By Dr. J. C. Cain. Second edition. Pp. xii+199. (London: E. Arnold, 1920.) Price 12*s*. 6*d*. net.

THE important chapter in organic chemistry which is summarised so admirably by the author of the treatise under review affords a striking illustration of the difficulty of explaining the details of a chemical synthesis to a non-chemical, although scientific, audience.

The element carbon furnishes the framework or skeleton of all organic compounds, but much of the chemical liveliness appertaining to the more reactive of these substances is due to nitrogen, an element endowed with a dual personality. In the free state inert and loath to enter into chemical combination, when combined it becomes extremely active. Everything living that grows contains nitrogen, and this element is also present in all organic explosives and in the physiologically active alkaloids. It is, therefore, not surprising that the study of organic nitrogenous substances has always had a great fascination for chemists, who have never grown tired of speculating on the molecular structure of these compounds. It was from this academic point of view that about sixty years ago Prof. Kolbe, of Marburg, set his pupils to work on the action of nitrous acid on various aromatic amines, nitrogenous compounds of the ammonia type derived from the aromatic hydrocarbon, benzene. One of these workers was Johann Peter Griess, who, on treating picramic acid with nitrous acid, discovered the first diazo-compound, so called because its molecule contained a very reactive group, N_2, consisting of two atoms of nitrogen or azote.

Purely as a matter of scientific curiosity and without any thought of possible applications, Griess proceeded to generalise this reaction and succeeded in showing that the common primary aromatic amines yielded diazo-compounds. These diazo-derivatives, he found, were very reactive compounds, and he tried their action on all possible substances. He was thus led to make a discovery of the utmost technical importance, namely, the synthesis of the azo-colouring matters. The diazo-reaction itself was discovered in 1858, and Griess obtained the first azo-colour in the years 1861–62. This dye was first manufactured in 1865 by Caro, a German chemist then employed by Messrs. Roberts, Dale, and Co., of Manchester. The greater part of Griess's work was carried out in England, first in London in Hofmann's laboratory, and afterwards while engaged with Messrs. Allsopp, of Burton-on-Trent.

From those early days to the present time the diazo-reaction has gone on becoming increasingly useful both in technical and in academic chemistry. The azo-colours produced a revolution in the art of dyeing because a large and important group was found to have the valuable property of dyeing cotton directly without the intervention of a mordant. Other azo-dyes have found useful application as extremely fast mordant dyes on wool. A third group, the azo-pigments or ingrain dyes, are formed within the textile fibre by impregnating this material successively with the components of the azo-coupling. All students of organic chemistry are familiar with the Sandmeyer and Gattermann reactions, by means of which diazo-compounds become synthetic agents useful in elucidating the constitution of aromatic or benzenoid derivatives. The diazo-reaction has been of service in the production of synthetic drugs, notably those of the salvarsan group. It was employed during the war in the manufacture of sternutatory materials for chemical warfare. These synthetic developments are all duly noted in Dr. Cain's treatise, which includes many references to original literature. To the student of historical chemistry not the least interesting chapters will be those on the theories of the constitution of diazo-compounds. This discussion

deals fully with the celebrated Hantzsch-Bamberger controversy, which was maintained for several years. The author has himself formulated a theory of the constitution of diazonium salts which, with a modification suggested by the reviewer, is sufficiently elastic to account for the properties of aromatic diazo-compounds and also for the existence of a rapidly increasing group of heterocyclic and non-aromatic diazo-derivatives. A new chapter on the latter group has been added to this second edition of a unique monograph.

G. T. M.

Ancestral Studies of Compositæ

The Origin and Development of the Compositae: Thesis approved for the Degree of Doctor of Science in the University of London. By Dr. James Small. (*New Phytologist* Reprint, No. 11.) Pp. xi+334+6 plates. (London: William Wesley and Son, 1919.) Price 15s. net.

THERE is perhaps a tendency among systematic botanists to fight shy of the Compositæ, on account largely of the enormous size of the family, and the difficulties of properly classifying its members. Those, however, who once succeed in passing these lions in the path soon become enthusiastic students of the group, and Dr. Small is no exception to this rule. His contribution to the investigation of the origin and development of the family is by far the most important that has appeared for many years.

After a general discussion of previous literature, in which the most important names are those of Cassini and Bentham, the author goes on to deal with the various morphological and ecological features of the family one by one, considering, for example, the pollen-presentation mechanism, the corolla, the pappus, the involucre, the receptacle, the phyllotaxis, and the fruit dispersal. From all of these, similar general conclusions are drawn, to the effect that the Senecioneæ are the most primitive type of the family, and that from them, directly or indirectly, and ultimately from Senecio itself, as the basal genus from which the Senecioneæ arose, there sprang all the other tribes and genera of the family. This is then very strikingly confirmed by a study of the geographical distribution, which shows what would be expected upon this theory of mutational origin, and upon the hypothesis of age and area, which is likewise adopted. It is shown that the distribution of Senecio (the oldest genus) is the widest of all, and that of other tribes and genera less and less in proportion to their lesser age.

Senecio is supposed (and the evidence is fairly clear) to have arisen from the Siphocampylus group of Lobelioideæ, and probably in the Bolivian highlands after the upheaval in the Cretaceous period had provided available land above the limit of trees. Once formed, its pappus fruit and the great area of open land available in the mountain chains which, with few breaks run all round the world enabled it to spread rapidly over America, Asia, Africa, and Europe.

In the final chapter an interesting sketch is given of an hypothetical evolution of the Compositæ from Senecio, based upon the various conclusions drawn in the course of the work, summed up largely in a diagram on p. 297, which illustrates this evolution in time and space. The second great genus to evolve is supposed to have been Gnaphalium (from which the Inuleæ are descended), then Spilanthes (Heliantheæ), Solidago (Eupatorieæ and Astereæ), and so on. The whole is a striking and interesting illustration of the way in which our whole outlook upon phylogeny has been altered by the acceptance of the modern theories of evolution and geographical distribution.

In the course of the work many minor points are further elucidated, such as irritability in the pollen-presentation mechanism. Good reasons are brought forward for supposing the pappus to be of trichome nature, and by an ingenious mechanism the dispersal of the seed was studied; and it was shown that a very slight wind was sufficient to keep the seeds aloft in sufficiently dry air, so that there is no need for land bridges to explain the distribution. Many other points are also dealt with, for which reference must be made to the original.

Our Bookshelf.

Monarch: The Big Bear of Tallac. By Ernest Thompson Seton. Pp. 215. (London: Constable and Co., Ltd., 1920.) Price 7s. 6d. net.

THIS is a composite picture of a grizzly bear, or, more exactly, the personality of one remarkable bear still living in prison has been credited with the adventures of several of his kind. Beginning with the growth and education of the cub, the book tells the story of many ups and downs, such as the first sheep-stealing, the escape from the forest fire, the circumvention of the hunters; the affair of the ten-gallon empty sugar-keg with the delicious smell, into which the bear thrust his head; and the final capture (by means of drugged honey) of an adventurer with many aliases. Mr. Thompson Seton is a fine raconteur, but we wish he had put a little more stuffing into the book; and his literary facility sometimes gets

the better of his judgment. "And still he lives, but pacing—pacing—pacing—you may see him, scanning not the crowds, but something beyond the crowds, breaking down at times into petulant rages, but recovering anon his ponderous dignity, looking—waiting—watching—held ever by that Hope, that unknown Hope, that came." Throughout the book we get glimpses of a river that does not reach the sea, and a poetic parallelism is sustained between river and bear—both ending in imprisonment. "The river, born in high Sierra's flank, that lived and rolled and grew, through mountain pines, o'erleaping man-made barriers, then to reach with growing power the plains and bring its mighty flood at last to the Bay of Bays, a prisoner there to lie, the prisoner of the Golden Gate, seeking forever Freedom's Blue, seeking and raging—raging and seeking—back and forth, forever—in vain." So with the bear. The book is delightfully printed and got up, and many of the thumb-nail drawings are very graphic. We are told on what pages they occur and on what pages the chapters begin and end, but there is no pagination!

Religion and Culture: A Critical Survey of Methods of Approach to Religious Phenomena. By Dr. Frederick Schleiter. Pp. x+206 (New York: Columbia University Press, London: Humphrey Milford, 1919.) Price 8s 6d net

IT is well to be reminded by such an acute critic as Dr. Schleiter that anthropology, one of the youngest of the sciences, is still in search of the one scientific method of analysing and co-ordinating the enormous mass of material which has been, and is still being, collected. The object of this book is to review the methods in use at present and to point out certain difficulties which each involves. Though in his preface the author tells us that he has in some degree modified his iconoclastic attitude towards the comparative method, his criticism still remains sufficiently drastic. Thus he remarks that "in his immensely voluminous works" Sir James Frazer has embodied "several mutually irreconcilable types of research." Again, the method of intensive study of a limited group of cultural facts—the Australian culture, for instance—"bristles with fallacies and insupportable pre-suppositions" In dealing with Mana, Dr. Marett "appears to have expressed bewildering varieties of opinion on this subject." Sir E. Tylor postulates "a single coherent and systematic view of the world, or what he repeatedly refers to as a 'philosophy of nature.'" But "all ethnological evidence tends to show that no such universal systematisation of experiences has ever taken place." In short, "ethnographical literature, as a whole, presents to us little more than groups of classifications carried out from mutually irreconcilable points of view—the advocates of the separate principles being gathered into schools which profoundly distrust each other's results."

Dr. Schleiter, though an acute critic, is not a lucid writer, and his work is critical rather than constructive. He supplies a bibliography, but, strange to say, no index. We can do no more at present than indicate the scope of this important review of methodology applied to ethnography.

Manuel Pratique de Météorologie. By J. Rouch. Pp. viii+145+xiv plates. (Paris: Masson et Cie, 1919.) Price 6.50 francs net.

THIS book, the outcome of war experience especially with aviators, is designed to give those who receive weather forecasts some knowledge of the principles on which they are based. The greatest measure of success is likely if the recipients have this knowledge, and are also in personal contact with the forecaster.

The construction of weather charts, the interpretation of their broader features, and the travel of large weather systems are dealt with in the first eight chapters. The greatest danger, however, often attends the passage of smaller travelling systems. Accordingly, chap. ix. discusses in great detail secondary phenomena, line squalls, thunderstorms, etc. Fog has a separate chapter, and an account is given of the main results of recent upper-air research. A useful feature is a list of the chief barometric situations of the year 1917 to serve as examples supplementary to those given in the book. The published daily charts of the Bureau Central Météorologique may be obtained for this purpose.

Detail is not lacking, and physical explanations are given of many phenomena. The book should appeal to meteorologists, as well as to "those who, without being meteorologists, wish to know what the weather will do." M. A. G.

Wireless Transmission of Photographs. By Marcus J. Martin. Second edition, revised and enlarged. Pp. xv+143. (London: The Wireless Press, Ltd., 1919.) Price 5s.

A CERTAIN amount of experimenting has been done from time to time on the transmission of sketches, photographs, etc., electrically along ordinary telegraph circuits, but in the case of long lines success has been limited by the difficulty of obtaining sufficiently sharp current impulses owing to the capacity effects in the line. This difficulty disappears with wireless transmission, and it is chiefly for this reason that the author anticipates greater success, as well as greater convenience, in the apparently more delicate methods which it is his purpose to describe. In his own system a bichromate print made on a metal film is rotated on a drum at the same time fed axially, and a stylus is caused by the presence of the picture to make intermittent contact and to send a series of impulses from an ordinary wireless transmitting set. A synchronised drum at the receiving end carries a photographic film, and a beam is directed on to it, which is made intermittent by the movement of a small shutter controlled by the receiving apparatus. Considerable ingenuity has been exerted to overcome the many practical difficulties encountered. The additions to this the second edition relate chiefly to optical and photographical matters.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Organisation of Scientific Work in India.

As NATURE waited for more than a year to criticise the Indian Industrial Commission's Report which was published in October, 1918, it will probably tolerate this additional delay of a few weeks (due to my absence in India) in attempting, on behalf of my colleagues, to demonstrate that the impressions conveyed by the leading article in the issue of February 19, and by the letters which followed in three later issues, bear little resemblance to the Commission's proposals for "the organisation of scientific work in India."

We are well aware out here that the writer of the article borrowed many of his expressions, and that the correspondents who furnished the subsequent applause obtained their impressions of the Industrial Commission's scheme from a memorandum which was privately composed and circulated among a few scientific men in England after the departure of the only two members of the Commission who were at home last year on leave. If I had seen the private memorandum only, I, too, should have added my vote to the others in condemning a scheme apparently designed to tamper with the form of liberty that is essential to scientific research; and I doubt if I should have shown the canny wisdom of a distinguished chemist who, in reply to the author of the memorandum, cautiously commented on "proposals *said to have been* set forth in the report of the Indian Industrial Commission." That most of your distinguished correspondents had not read the Commission's report itself is obvious enough from their letters, though only one of them frankly says so. One writer, for example, states that "under the centralisation scheme the work of an investigator would depend on the previous sanction of the head of the Service, who would probably not be of any scientific eminence, or might even be without scientific qualification." The one obvious and plainly stated object of the Commission's scheme is to release isolated scientific research workers from control by non-scientific officials, and it is so designed that even the scientific officer suggested for the head of each Service cannot do more than criticise and advise without interfering.

According to the privately circulated memorandum, "two policies are at present in the field: (*a*) absolute centralisation with the formation of distinct, water-tight, graded departments of science (botany, zoology, chemistry, etc.) being controlled by a separate departmental head." This is intended to represent the policy of the Industrial Commission, and the literal agreement between the statement in the leading article of February 19 and three-quarters of this quotation is as important to notice as the additions made by the writer of the article. Both, like your correspondents, have confused the wholly distinct terms "services" and "departments," which are clearly distinguished in the Commission's report; but the writer of the article has also gratuitously added a statement which neither the Industrial Commission nor any other responsible body here has ever suggested, namely, the placing of "botanists, zoologists, and so on," under the proposed Imperial Department of Industries.

Your correspondents, out of the fullness of their successful experience, reproduce many well-worn platitudes on the freedom necessary for research, but they overlook the fact that many young scientific officers are employed for such accessory routine duties as analyses and identifications, which may be dull, but are essential to the operations of agriculture, forestry, and mineral development. They forget, too, that most of the so-called research work of many others is purely descriptive, which is equally essential in a country stocked with raw materials of unknown nature. Unless their work comes to the notice of a senior authority of their own caste, young scientific officers so employed in departments or institutions controlled by non-scientific officials would rarely get a chance of showing their worth or of justifying their desire for research opportunities; unless they are members of some "service," and thus come automatically to the notice of their scientific chief, they must either remain low-paid "hewers of wood" or refuse to renew their agreements and quit.

Then among those who already enjoy opportunities for research there are some who need the support of an independent senior authority in their desire to obtain the necessary freedom and funds from the local authorities in control; and it matters little whether the "constituted authority" be a committee, a board, a hidebound official, or our most senior of scientific councils, which Prof. Soddy regards as the obsolete product of inbreeding, for all have learnt the danger of taking unchecked the average man's estimate of his own worth. There are some, too, among our isolated scientific workers who have not sufficient confidence in themselves to close their inquiries for publication; they need the crystallising influence of a senior worker who has the right to ask them how they are getting on with that piece of research which was in progress last year; there are others who, distracted by the abundance of their ideas and the wealth of available raw material, pass from one inquiry to another without finishing any; there are some who, in their isolation, unwittingly waste time in pursuing lines already more completely developed but not yet published elsewhere. Then there are isolated workers who, for want of a pacemaker, grow weary in well-doing; and, finally, there is the inevitable residue who, through uncontrolled freedom, become charlatans. But although all these well-known species of scientific men are represented in India, I doubt if we have any here who have yet attained such experience and dexterity in the use of "scientific method" as to justify their criticising a report that they have never seen.

Your leading article of February 19, after referring to the research work done in existing institutions of various sorts, asserts that "the present system has proved successful in practice." It would not be fair, nor would you find space, to describe the painfully numerous exceptions; but if the situation must be summed up in only a few words, the following two statements are sufficient: (1) During its tours the Industrial Commission received complaints nearly everywhere of the disabilities that handicap scientific workers under the present "system"; and (2) the most conspicuous success is also the most centralised institution of all, namely, the Geological Survey, which is a Department as well as a Service.

We cannot hope to provide for other scientific workers the amenities now secured by the geologist; he inherits the results of the forethought of a distinguished scientific worker who had also a genius for administration—Dr. Thomas Oldham. But it was the hope of the Industrial Commission to devise a scheme which (taking into account established vested interests, the tendency towards provincial autonomy,

and the transfer of some provincial scientific institutions to the control of popular representatives necessarily anxious for visible results) would retain for scientific workers the security of a central Service, and, so far as their research activities are concerned, the advantages of the support and criticism of a senior officer of their own caste. Our scheme is not an attempt to impose arbitrary control, but a simple response to a general petition from scientific workers for protection and support.

It cannot be applied, however, without suitable modification to fit established interests and institutions. There are, for example, forest botanists who are forest officers first and botanists after; their bond with the Forest Service is closer than with the Botanical Survey, and both should be developed as complementary, not competing, Services. There are agricultural chemists whose community of interests with the rest of the Agricultural Service forms a stronger service link than their affinities to other chemists; they might more appropriately be termed chemical agriculturists, and, having one of their own, they need not form part of the suggested Chemical Service.

To find out whether the general principles suggested by the Commission are applicable at all to each of the major sciences, and, if so, to adjust the scheme to established conditions, requires examination by special committees. One such committee for chemistry under Prof. J. F. Thorpe has just published its report, from which it will be seen that a committee composed of six chemists and one administrative officer, after examination of witnesses and institutions in various parts of India, accepts for chemists the scheme which your correspondents, rashly believing a privately concocted memorandum, label as "servitude undisguised," a "means of encouraging mediocrity," "bureaucratic centralisation," and other epithets.

To those of your readers who do not know the motive of the private memorandum referred to above, the special reasons for delaying the date for its distribution to every member of the Royal Society's Indian Advisory Committee—except myself, its chairman—and the selection of "the solid ground of NATURE" as the *point d'appui*, this "mass attack" on the Industrial Commission's scheme has doubtless all the appearance of spontaneity and honest conviction.

By an official accident, not foreseen by the author of the private memorandum, I have now before me (1) a proposal from a committee of botanists for the enlargement of the Botanical Survey, and (2) the unsought advice of a forest botanist who, through commendable but over-jealous regard for his own institution, submits opinions collected from ingenuous scientific men and the correspondence in NATURE in support of his proposal, not for the expansion, but for the limitation of the Botanical Survey to one cryptogamic botanist and three specialists in medicinal plants. And this in a tropical and semi-tropical country covering 1,750,000 square miles! Fortunately, there is enough evidence available to justify further support for, and the independent maintenance of, both botanical institutions; but the petty jealousies of those who suffer from this form of mental astigmatism scarcely reinforce one's efforts to secure for isolated unorganised workers in other sciences the benefits now enjoyed by the geologist, or to secure for all scientific workers in India the privileges and recognition long ago accorded to engineers, doctors, and the members of the Indian Civil Service.

THOMAS H. HOLLAND,
President, Indian Industrial Commission.
Simla, May 5.

[The leading article to which Sir Thomas Holland refers described the proposals of the Indian Industrial Commission and discussed the policy of centralisation and the creation of graded scientific Services in comparison with the present system under which research is carried on in India. In the correspondence which followed attention was given chiefly to the general principles of "Organisation of Scientific Work," and it was not necessary to be familiar with the Report of the Commission in order to express opinions upon these, or to urge that creative investigators produce their best results when they are given perfect freedom of action. The proposed scientific Services of India may, as regards their aims, be compared with the Industrial Research Associations at home, and are similarly capable of promoting progress in both pure and applied science. But the work carried on at universities and research institutes by men outside official Services has even greater need of financial support, because its value is not so readily understood. This is the aspect of productive research with which we are particularly concerned, and for which we ask full consideration.—ED. NATURE.]

Anti-Gas Fans.

I HAVE read Mrs. Ayrton's letter in NATURE of June 3, after, unfortunately, missing the note in the issue of May 13, as well as the *Times* correspondence referred to. I have no intention of entering into a controversy, polemical or otherwise, with Mrs. Ayrton, but should like to put my views before your readers, as I believe them to be shared generally not only by Headquarters Gas Service officers, but also by regimental soldiers of all ranks, including Gas *personnel*.

The crux of the matter is this: The problems involved in gas defence after July, 1917, when the enemy commenced using "mustard gas," were of a totally different nature from those which had to be faced before that date. Then, apart from small quantities of the annoying, but otherwise practically innocuous, "tear gas," we had to deal with moderate quantities of lethal gas shell, containing the *volatile* "diphosgene," and, very occasionally, with waves of cloud gas. Under those conditions the gas, except in very cold weather, disappeared quickly (a matter of minutes) from the open, or even from trenches of average depth, but was liable to collect and remain in shelters for hours, or even days. When such shelters had been once cleared they were habitable, as no "gas" remained outside in the neighbourhood to contaminate them further. For this purpose the Ayrton fan was found to be useful, and large numbers were issued as trench stores. Later the more simple, and quite as efficacious, method was introduced of merely lighting a small fire in the shelter, and thus causing a through draught. This was found to be distinctly superior for deep shelters, such as those in the chalk country of the Somme battlefield, and, moreover, was far less fatiguing to the men employed. Working an Ayrton fan, even in the most approved fashion, when wearing a gas-mask on a hot day, is a tiring task.

After the date mentioned we had essentially to deal with a relatively *non-volatile* shell-filling, which produced its well-known effects at concentrations far below those at which the volatile fillings became innocuous, and was used by the enemy in very large quantities. This gave little warning of its presence to the uninitiated, soaked much of the ground and pervaded the whole atmosphere in the shelled area for days afterwards, made great demands on the endurance and discipline of the soldier, and called for quite new measures. This is not the place to discuss these measures, but it is clear that the use of either fire or

fan to remove gas from shelters could really be effectual only after first dealing with the area round the shelter. That is one reason for the relative decline in the fortunes of the Ayrton fan. I say *relative*, as large numbers of such fans were issued even during the winter of 1917–18, and, for all I can remember, still later. Other reasons were the natural and rooted objections of the regimental officer and soldier respectively to be responsible for, or to load himself with, stores of (to him) problematical value, and the growing favour shown to the alternative fire method. (It was said, perhaps not without malice, that Ayrton fans were often used for clearing shelters from gas—by fire!)

However that may be, there was no demand by troops for the fans towards the end of the war; on the contrary, we were besought to withdraw them. I know this myself from many personal interviews with regimental officers and from reports furnished by Gas *personnel* of every type of unit and formation. There were, of course, up to the end of the war gas casualties caused by men sleeping in shelters which might have been successfully cleared of gas either by the fan or by fire. They were, however, owing to the particular properties of "mustard gas," a small proportion of the whole; and fatigue and ignorance and the exigencies of the battle were their causes.

I must, therefore, characterise as quite unfounded the view that much suffering and loss of life could have been avoided by increasing the provision of Mrs. Ayrton's fan. Regimental and Gas Services *personnel* were both far too anxious to reduce gas casualties in every way practicable. It was ultimately the fighting soldier who decided, after weighing all the facts of the situation, that the fan, useful in sound and well-established trenches, was scarcely "worth while" during the advances and retirements of 1917–18 or in the mud and pill-boxes of the Ypres salient—this apart from the question of "mustard gas." Mrs. Ayrton is very obviously sincere, but, like another distinguished civilian who has recently written on camouflage, is not quite *au fait* with the realities of the battlefield. Exaggerated attacks of this nature on the War Office are liable to defeat their own ends, and also to neutralise the efforts of others who are trying to ensure the application of scientific methods to military problems in a more systematic manner than has been the case in the past.

Attainment of High Levels in the Atmosphere.

I MUST confess that I am very sceptical as to a sounding balloon having reached 37,000 metres or a pilot balloon 39,000 metres, as mentioned in NATURE for June 3, p. 437, although such heights would be possible if sufficiently large balloons were employed.

A sounding balloon as commonly used is a small india-rubber balloon expanded by hydrogen to about twice its natural diameter, and then securely tied up. The rubber stretches as the balloon ascends, until finally it can stretch no further and the balloon bursts. Under the supposition that the pressure and temperature of the gas inside are the same as those of the air outside, and under average conditions of temperature for Europe, the following rules hold: The starting diameter is doubled at a little more than 16 km., trebled at a little more than 24 km., and quadrupled at 30 km. Since the starting diameter is about double the natural diameter, this means that at 30 km. the rubber has stretched eightfold linearly and its thickness been reduced sixty-fourfold. I do not think any rubber that will stand this treatment can be found.

On the other hand, a precise calculation of a great height is in practice impossible. We can only measure the pressure, and when the air pressure is greatly reduced a very small error in the pressure makes a large error in the height.

For a pilot balloon, if the balloon is near the zenith and the base line for the theodolites a long one, there is not so much risk of error; but if, as is usually the case, the balloon has drifted a long way, particularly if it has drifted in the direction towards which the base line points, then a small error in the setting of the theodolites or in reading the angles will make a great error in the height.

It is desirable that when the recorded height has reached an abnormal value the computer should give full details and state his reasons for believing it to be genuine, otherwise one is apt to think some mistake has crept in.

W. H. DINES.

Central Wireless Station for Astronomy.

IN the "Astronomical Column" of NATURE of May 27 it is stated that "Prof. Kobold, editor of *Astr. Nachrichten,* and director of the Centralstelle, delegated the latter work to Prof. Strömgren, Copenhagen, during the war, but has now resumed it, and announces in *Astr. Nach.,* 5044, that arrangements have been made for the distribution of astronomical information by wireless telegraphy from the Nauen station."

It will be remembered that, in pursuance of resolutions adopted by the International Scientific Academies at London and Paris in 1918, there was established at an international conference held at Brussels in July, 1919, among other Commissions, a Commission of Astronomical Telegrams, with a central bureau at the Royal Observatory of Belgium (Uccle), to replace Kiel, for the purpose of receiving, centralising, and dispatching information concerning astronomical discoveries, observations, and calculations, either by telegram or post, to the various institutions or private persons subscribing to it.

Surely with such an organisation in full working order this Commission should undertake the dispatch by wireless of astronomical information of great urgency, such as the appearance of a new star, etc., if such information is going to be distributed by wireless at all!

Practically every observatory in Western Europe now takes in the time and weather signals from the Eiffel Tower, and any news of an astronomical nature could be easily transmitted to that station from the central bureau at Uccle (or Brussels) and re-transmitted from the Eiffel Tower at, say, 10.00h. and 16.00h., the standard times of transmission of the time and weather signals.

Before the war the Central Bureau of Astronomical Telegrams was located at Kiel, but this organisation has *ceased to exist* from an international point of view. There seems no object, therefore, in reviving it at Nauen (near Berlin) purely for the sake of this wireless astronomical information, when this mode of dispatch can be as easily adopted in Western Europe for this purpose.

Prof. Kobold seems not only to ignore the existence of the new International Central Bureau in Belgium, but also assumes that the war has made "no difference."

The "Flight" of Flying-fish.

I HAVE on frequent occasions (in the Mediterranean, the Red Sea, and the Indian Ocean) carefully observed with a field-glass ($\times 8$) the supposed "flight" of flying-fish, and have always concluded that the "leap and glide" theory is the correct one, with one or two modifications. Dr. J. McNamara, in NATURE for June 3, p. 421, cites five facts in support of the theory of true flight, but I may point out that all these five facts can be otherwise interpreted. Flying-fish undoubtedly leap out of the water and gain their initial impetus by tail action, and when out of the water the pectoral fins serve as planes. While gliding the fish can not only renew its impetus to a limited extent by an occasional flick of its tail against the crest of a wave, but, as your correspondent says, can also change the direction of its glide. I have, however, never observed a fish "come back in a direction opposite to the direction in which it set out," and I am tolerably certain that it could not do this without re-immersion in the water, unless perhaps a strong wind were blowing in this opposite direction. Flying-fish can certainly rise and fall during the glide, but this, as well as change of direction, can be easily explained by assuming inclinations of the planes of the fins—a very different process from actual "wing"-flapping sufficient to cause flight. The fins can, like those of most fishes, move on their bases, but I fail to understand how, in the absence of the required musculature, it can possibly be supposed that the fins show "rapid movement, as in the case of hovering flies and humming-birds." If seagulls can glide for hundreds of yards, rise and fall, and change direction without wing-flapping, why not flying-fish? In gliding the outlines of the pectoral fins naturally appear to be indistinct, because, compared with the rest of the body, the fins are thin and irregular in outline on their posterior edge.

Granting that the body can gain fresh impetus by an occasional flick of the tail against a wave-crest (and this can be easily seen to occur, and is certainly less difficult to understand than the initial tail action which enables the fish not only to emerge from the water, but also to acquire an impetus which carries it the greater part of its glide), and that the planes of the wings can be inclined, all the movements of flying-fish which I have observed are fully intelligible.

W. N. F. WOODLAND.

"Kismet," Lock Mead, Maidenhead, June 4.

As another observer of Nature at sea I must beg to differ entirely from Dr. McNamara's conclusions on the "flight" of the flying-fish.

(1) Turning at an acute angle can be brought about by an extra puff of wind, and indicates no power on the part of the fish.

(2) It is impossible for a flying-fish to flap its pectoral fins as a bird does its wings.

(3) The rise and fall over waves are due to the forcing up or lowering of the air immediately over the surface of the water.

(4) The impetus is quite sufficient to send flying-fish up to a height of 50 ft. or even more, and to extend the soar to 300 yards. They naturally flop about on deck until dead.

(5) It is quite possible (though I have never seen it) for the tips of the fins to be vibrated by the wind during flight.

The matter has been dealt with more fully in "Nature Notes for Ocean Voyagers," by Capt. Alfred Carpenter and myself, and also in the *Nautical Magazine* for May, 1894, and in the *Shipping World* for April, 1901. The late Capt. Cromie, at my request, made a series of very careful observations from torpedo-boat destroyers and submarines, and was most emphatic that they did not "*fly*."

As in many other interesting problems, the help of a super-kinema camera fitted with a telephoto lens would be of great service. DAVID WILSON-BARKER.

Fellow-Workers.

IN NATURE for June 3, p. 416, Prof. D'Arcy Thompson refers to me and to my "fellow-workers" who helped me to bring our "hopes to fruition" in connection with the old malaria-mosquito business. My own memories remind me of seven years' almost continuous solitary labour, during which time my numerous "fellow-workers" had many opportunities, as good as mine or better, for doing the same work, but, oddly enough, did not use them; and it was not until I had solved the problem that they arrived on the scene in a body, fully armed with paper, pens, and cameras, and resolved "to join the victory group" at any cost. Prof. Thompson puts one of these gentlemen in the place of honour next to Pasteur—who, by the way, had little to do with the development of animal parasitology. The true history of the subject is given in my "Prevention of Malaria" (Murray), and still more trenchantly in Robert Koch's letter to me, dated February 10, 1901, and published in *Science Progress* for April, 1917.

But this is a detail; and I should like to thank Prof. Thompson for his kindly references to my medical verses, and for his interesting conspectus of the medical poets. Oddly enough, the day after it appeared in NATURE I lectured at the Royal Institution on "Science and Poetry," and upheld the thesis that a higher view of both will show how frequently and how closely they are connected. But honesty compels me to add that my own interest in medical matters is quite secondary, and a matter of duty rather than of predilection. RONALD ROSS.

36 Harley House, London, N.W.1, June 4.

The Approximate Evaluation of Definite Integrals between Finite Limits.

(1) THE four-ordinate rule given in my letter published in NATURE of May 20, p. 354, viz.

$$\int_0^1 F(x)dx = \tfrac{1}{4}\{F(\tfrac{1}{10})+F(\tfrac{4}{10})+F(\tfrac{6}{10})+F(\tfrac{9}{10})\},$$

is obtained by dividing the range into two and to each half applying the simple two-ordinate rule,

$$\int_0^1 F(x)dx = \tfrac{1}{2}\{F(\tfrac{1}{5})+F(\tfrac{4}{5})\},$$

the parabolic or cubic approximation for two ordinates being

$$\int_0^1 F(x)dx = \tfrac{1}{2}\left[F\left(\frac{3-\sqrt{3}}{6}\right)+F\left(\frac{3+\sqrt{3}}{6}\right)\right]$$

$$= \tfrac{1}{2}[F(0{\cdot}2113)+F(0{\cdot}7887)]. \quad . \quad . \quad (a)$$

(2) Closer approximations may be obtained by dividing the range into a greater number of parts and applying this rule to each, thus:

$$\int_0^1 F(x)dx = \int_0^{\frac{1}{3}} F(x)dx + \int_{\frac{1}{3}}^{\frac{2}{3}} F(x)dx + \int_{\frac{2}{3}}^1 F(x)dx$$

$$= \tfrac{1}{3}\left\{\int_0^1 F\left(\frac{x}{3}\right)dx + \int_0^1 F\left(\frac{1+x}{3}\right)dx + \int_0^1 F\left(\frac{2+x}{3}\right)dx\right\}$$

$$= \tfrac{1}{6}\{F(\tfrac{1}{15})+F(\tfrac{4}{15})+F(\tfrac{6}{15})+F(\tfrac{9}{15})+F(\tfrac{11}{15})+F(\tfrac{14}{15})\}$$

The following table shows for several functions the value of the integral and the approximate evaluations from two, four, six, and eight ordinates:

F(x)	$\int_0^1 F(x)dx$	Number of ordinates used. 2	4	6	8
Semicircle $(x-x^2)^{\frac{1}{2}}$	0·3927	0·4000	0·3949	0·3939	0·3934
Quadrant $(1-x^2)^{\frac{1}{2}}$	0.7854	0·7898	0·7868	0·7862	0·7859
Parabola x^2	0·3333	0·3400	0·3350	0·3341	0·3337
$\sin x$	0·4597	0·4580	0·4593	0·4596	0·4596
$\log(1+x)$	0·3863	0·3850	0·3859	0·3861	0·3862
e^x	1·7183	1·7234	1·7197	1·7187	1·7186
$\frac{1}{1+x}$	0·6931	0·6945	0·6937	0·6934	0·6933

(3) If $F(x)=a+bx+cx^2+dx^3$,

$$\int_0^1 F(x)dx=\tfrac{1}{3}\left[F\left(\frac{2-\sqrt{2}}{4}\right)+F(\tfrac{1}{2})+F\left(\frac{2+\sqrt{2}}{4}\right)\right]$$
$$=\tfrac{1}{3}[F(0{\cdot}1464)+F(\tfrac{1}{2})+F(0{\cdot}8536)]. \quad . \quad (b)$$

A simple three-ordinate rule is therefore

$$\int_0^1 F(x)dx=\tfrac{1}{3}[F(\tfrac{1}{7})+F(\tfrac{1}{2})+F(\tfrac{6}{7})].$$

In practice this is not quite so convenient as the application of the two-ordinate rule.

A. F. DUFTON.

Trinity College, Cambridge, May 20.

P.S.—I thank Mr. C. F. Merchant for pointing out in NATURE of June 3 that the four-ordinate rule is already in use, and for giving a reference to Tchebycheff's rules, with which I was unacquainted. The positions of Tchebycheff's ordinates, as in (a) and (b) above, are inconvenient, and the rules obtained by taking neighbouring ordinates attain simplicity without great loss of accuracy. A. F. D.

June 5.

The Cost of Laboratory Fittings.

IT is evident from the correspondence which has followed the publication of the letter from me on the subject of laboratory fittings that I must again ask leave to trespass on your space in order to explain that my remarks referred solely to fixed fittings, as stated, embracing working benches, lecture tables, and the like. I have no doubt that questions of actual instruments and apparatus are of much greater importance, but of these I have no right to speak.

Perhaps I may be allowed to make myself clear by reference to one or two specific directions in which research on fixed fittings might possibly prove useful. The present price of teak as bought in bulk from a merchant is 30s. per cubic foot, and if impregnated soft wood could be substituted for bench and table tops much saving would result. This impregnation might be effected by precipitation, electrolysis, oxidation (oils), or evaporation (*e.g.* silica solutions). Again, bituminous materials with perhaps barytes rolled into them might be investigated for use as a thin layer on wood or concrete. Soapstone is much used in America and *lave émaillée* in France, but not as yet in this country. There are, further, certain hard flooring plasters which should be very inert chemically. An investigation is much needed into the proper composition of bituminous materials for coating laboratory drains. Drains executed in wood thus coated are in many cases much cheaper than glazed ware drains.

For repetition work such as locker doors and even drawers pulped and stamped material might prove economical if some standard could be agreed upon. It should not be a very expensive matter to set on foot some researches of this nature, and any effective results would, I imagine, be very welcome to institutions at present faced with additions to their material equipment. ALAN E. MUNBY.

9 Old Square, Lincoln's Inn, W.C.2.

The First Act of a Young Thrush.

SINCE observations of the first acts of wild birds immediately after hatching are very difficult, the following may be worth recording. Last week I went to look at a thrush's nest which I had found a fortnight before, with four eggs in it. Two eggs were hatched and two were not. As I was watching the young birds, one of the two remaining eggs cracked right across, and I saw the bird wriggle out and toss the two halves of the shell out of the nest by a convulsive movement of its back; but the curious thing was that, before the bird was properly free from the shell, it opened its beak—as if for food. I dug up a worm near by and offered it to the bird, which swallowed it eagerly. I purposely dug for the worm in a place from which I could see the nest, and I feel sure that the parent bird did not come and feed the nestling meanwhile. A few minutes later the other egg hatched, and the bird behaved just as in the former case, opening its beak before it was out of the shell.

Now the question is: Was the opening of the bird's beak a reflex or an "instinctive" act? If it were reflex, it would presumably have been induced by sudden exposure to the new environment of open air; and, obviously, such a reflex act would serve the purpose of an "instinctive" one in this case. Moreover, is it not a question whether any "instinctive" act at so early a stage can be anything more than a reflex act thus adaptable to survival purposes —by natural selection if need be?

HONOR M. M. PERRYCOSTE.

Polperro, Cornwall, May 30.

Marat and the Deflection of Light.

CARLYLE's vivid portraiture of Marat as "horse-leech" and savage revolutionist has rather obscured the fact that this "friend of the people" was a learned doctor of medicine, a physicist, and a physiologist. It is true that Carlyle refers to him as "Renovator of Human Science, Lecturer on Optics," but the mistake about the "horse-leech" is repeated in the same passage.

In Marat's "Notions élémentaires d'optique" (1784), p. 16, the following statement is made:

"Il est hors de doute, que les rayons de lumière changent toujours de direction dans le même milieu, lorsqu'ils passent à certaine distance d'un corps. Se trouvent-ils dans la sphère d'attraction? ils se replient jusqu'à certain point à sa circonférence, et se prolongent ensuite en droite ligne."

This at first glance may appear a remarkable anticipation of recent discoveries in physics, but in reality the conclusion is based on wholly false premises, as further reading of the pamphlet will disclose. W. A. OSBORNE.

University of Melbourne, April 22.

British and Metric Systems of Weights and Measures.

ON p. 355 of NATURE of May 20 Mr. M. E. Yeatman in a letter on the above subject says: "It seems that the advantage of any given system of weights or measures lies largely in the facilities that it offers for the division of a sum or quantity into equal parts"; and I have seen "facility of factorisation" claimed before as one of the merits of the British system. As an engineer who "figures frequently," I fail to appreciate this fetish of factorisation. One uses a slide-rule and logs, and never worries about factors. Will Mr. Yeatman, or someone else, demonstrate the use of factors in practical calculations, bearing in mind the use of slide-rules, calculating machines, and logs?

The metric system seems to be gaining ground in spite of the lack of factors disclaimed for it.

ALFRED S. E. ACKERMANN.

Aircraft Photography in the Service of Science.

By H. HAMSHAW THOMAS.

AIRCRAFT photography as developed during the war possesses great potentialities as an instrument of scientific research. The value of the aeroplane in geographical and geological exploration has already been emphasised in these pages, and its employment in the reconnaissance of little-known countries need not be further mentioned; but if aeroplane exploration is valuable, its worth is greatly enhanced by systematic photographic work. For, while a trained observer notices many features, it is quite impossible for him to observe and note more than the salient points seen from a swiftly flying machine, while the camera instantly records every feature in the field of view. Again, from a safe height of, say, 10,000 ft. only the larger elevations or depressions are visible to the human eye, but if paired photographs are taken for the purpose of stereoscopic examination with a wide base of, perhaps, 500 yards, then the whole of the ground relief becomes visible in a most striking manner. But not only do photographs provide a means of obtaining and recording information; they also show the relative positions of objects, and, if taken on an organised system, provide a topographical survey for use in map construction.[1] In addition, I was frequently struck with the value for scientific purposes of material obtained in the course of the R.A.F. work in Egypt and Palestine, and the purpose of this article is to indicate some types of information which may be furnished.

Air photographs may serve either as useful illustrations of known scientific facts, or as a means of discovering new facts, and while they are mainly of geographical or geological interest, they may also assist the botanist, archæologist, and meteorologist.

Geography and Geology.—As examples of the illustration of known facts, we may mention the remarkable photographs of Vesuvius taken by Group Capt. A. E. Borton, C.M.G. One of these has already been published in the Press, and it would not be easy to find a more striking demonstration of the structure of a volcanic cone. Among the photographs taken in Palestine we had many good illustrations of erosion and river development. The soft lake-beds of the Jordan valley were shown in the process of weathering out to form what the Americans term "bad-land topography." In this region marls and clays which have been baked by the hot, rainless summer are denuded at a great rate by the heavy winter rains, and give rise to a complex system of steep-sided wadis spreading back from the main drainage channels. The sides of these wadis are bare of vegetation, but their bottoms become filled with scrub when reduced to the base level of erosion.

[1] See *Geographical Journal*, May, 1920.

The contrast between the wadi forms produced in these lacustrine or alluvial deposits and those carved out of the adjacent Cretaceous rocks is very noticeable, and we have also illustrations of the different erosion forms produced on steep or gentle slopes.

The River Jordan, which had never been very accurately surveyed before the war, has now been photographed over a considerable distance, and furnishes striking examples of some of the phenomena of river development. In its lower part it has cut down a distinct and well-marked meander-belt below the level of the surface of the lake-beds of the old valley. The river is constantly changing its course in this belt (see Fig. 1), which in most places is well covered with vegetation, and the old courses of the stream are often plainly visible where the vegetation has not yet had time to colonise the former river-bed. We see "ox-bows" and loops of the river in all stages of development, while sometimes a heavy spring flood appears to have resulted in the stream taking an entirely new course. At the sides of the flood-plain cusp-like terraces often show the stages in the cutting down of the gorge, while the presence of hard beds may produce nodes in the series of meanders.

FIG. 1.—Meander belt of the River Jordan north of Jericho, showing the formation of an "ox-bow" and the cusp-shaped terraces. The dark area near the stream is the belt of willow scrub.

The illustrations of such features as have been mentioned are often so striking and convincing that they would be valuable to teachers and students if they could be made available.

But by the study of photographs and the maps

made from them we may observe other features of research interest. The story of the earth movements in the Jordan rift is not yet clear, while there has been much discussion about the climate of the region during recent and prehistoric times. In some of the photographs taken, we have good evidence of very recent faulting, and we may distinguish a fault scarp in the lake-beds (Late Tertiary). We find that the trough faulting has resulted in the incision of many of the tributary streams, and in several places in cañon formation. When we look at the drainage system from the point of view of climatic change we find evidence of a former period of abundant precipitation, during which much of the present surface sculpture of the Judæan hills was effected; but this period was a remote one, and preceded the drying up of the Jordan lake to give the present valley. Passing up to the north of Palestine, we have good evidence from a dry gorge, terraced valleys and drainage forms, that at a former period the River Jordan originated in Central Syria; but afterwards the Syrian portion of the river was captured by the Litani. This capture was largely the result of a general uplift of the country, and several of the oblique air views of the coastal plain of Palestine, especially near Mount Carmel, show very well the plain of marine denudation stretching from the present shore to the foot of the hills.

It is in the portrayal of the geographical features in the most complete and detailed fashion, so that their developmental story can be studied and deciphered, that aeroplane photography excels. If the whole of the Palestine material could be carefully studied by the physical geologist, a great deal of information would result, for the above-mentioned deductions have been made from the study of a few small sets of photographs which had been chosen at random for other purposes.

The investigator of solid geology has naturally little to learn from photographs, but in some places, where the climate is arid and the ground almost devoid of soil, the boundaries of some of the harder beds may become visible, while in other cases the bedding is clearly seen, and the underlying structure may be brought out by surface weathering. A photograph taken during the first flight ever made from Egypt to India showed an interesting locality in western Persia, where a well-marked anticline had been laid bare by surface erosion.

Botany.—The student of vegetation who may be sufficiently fortunate to obtain aerial photographs of the ground is at once in possession of the basis of an ideal vegetation map. Different types of vegetation show up very clearly, and also, of course, the transition from desert to open and closed plant associations (see Fig. 2). It is naturally necessary to go over the ground with the photographs, but after a short time the characteristic tones and appearance of different vegetation types can be readily picked out. Even among crops it is possible to distinguish barley, wheat, and maize, besides other plants, like cotton, which have a distinct habit and growth period. Practical use of these facts was made in Mesopotamia for ascertaining the acreage under wheat cultivation, and trials have been made in India with the view of carrying out crop-surveys by aeroplane photography.

I have not had the opportunity of making many observations on this subject, but it may be of interest to mention a small point observed in connection with the distribution of the willow and tamarisk scrub of the Jordan valley. This vegetation is limited by the water supply from the river, and succeeds in following the stream right down to the Dead Sea. Here, at the mouth of the Jordan, although surrounded by salt lagoons, a narrow belt of vegetation manages to survive as a fringe to the river with its rapidly flowing stream of fresh water.

Archaeology.—The utility of aerial photography to the archæologist was strikingly illustrated in

FIG. 2.—Photograph showing the distribution of vegetation in the Sinai desert. The partial colonisation of sand-hills by dwarf scrub vegetation—the black spots—is well shown, also some small groups of date palms.

the case of the ninth-century city of Samarra,[2] in Mesopotamia, where views taken from above the apparently formless heaps of earth and rubble give the outlines and plan of streets and buildings. It may be only rarely that similar cases may arise, but experience shows that if ruins or remains exist in any regular form, their arrangement will be well depicted by the aeroplane camera. We may by this means be able to locate interesting sites which have been more or less obscured by superimposed material. A feature which was brought to light in Palestine as the result of air survey was the ancient irrigation system in the south-eastern part of the Jordan valley. An extensive series of old connected channels, now filled with scrub vegetation, was seen; this must be a relic of the days when the Jordan valley was under general cultivation,

[2] See Lt.-Col. G. A. Beazley, *Geographical Journal*, vol. liii., p. 330, 1919.

and very different from the desert condition which it possesses to-day. While nothing was found in Palestine of the same type as the Samarra ruins, the ancient Græco-Roman temples of Jupiter and Bacchus at Baalbek, in Central Syria, furnished some interesting photographs. A vertical view from about 3000 ft. gives a remarkably good ground plan of the present state of these beautiful remains (see Fig. 3).

FIG. 3.—Temples of Jupiter and Bacchus at Baalbek in Central Syria, showing the ground plan and some remains of later Saracenic building.

Meteorology.—The study of clouds by the photography from aeroplanes of their forms and features has been recently discussed by meteorologists, and need not be further mentioned.

It would be outside the scope of the present article to deal with the methods of obtaining, using, and interpreting the aerial pictures which have been referred to. It may be seldom possible for a scientific expedition to employ aeroplanes, owing to their expense; but, when it can be done, useful knowledge is bound to accrue. In other cases, however, as in Palestine, photographs may be taken for mapping or other purposes, which will also yield important scientific material to those who can make use of it; and possibly photographs taken for the purpose of training airmen may become of great value, even in this country, if certain areas are included. Sometimes the evidence furnished is clear and unmistakable, but in other cases the photographs have to be examined by a trained and experienced worker. The general public has not been very fully informed of the work of the R.A.F. photographers during the war, and to most people the air photograph is a curiosity which seems to have little value in times of peace. Though in some countries the civil importance of aerial photographic survey is realised, in England air photography is in a somewhat languishing condition. In these circumstances it is well to remember that, though the aerial camera has not been extensively employed apart from military work, it nevertheless appears to have no inconsiderable value in the domain of pure science.

The Dynamics of Shell Flight.

By R. H. FOWLER.

THE object of this article is to give a short account of some features of the motion of a spinning shell through air. Our knowledge of this phenomenon has been somewhat increased by war-time researches. To determine the motion of a shell from the equations of rigid dynamics, we require to know the complete force system which represents the reaction of the air on the moving shell; but, just as in the case of an aeroplane, the components of this reaction are utterly unknown *a priori*. The problem that arises, therefore, is that of determining these components by observation and analysis of the actual initial motion of shells. Once they have thus been determined, they can be applied, provided the essential conditions remain similar, to the calculation of the complete motion of a shell along its trajectory.

In the simplest case of all this procedure is classical. The air resistance to a shell, moving so that the directions of its axis and the velocity of its centre of gravity coincide, has long been determined thus as a function of the velocity, and trajectories have been computed assuming that this coincidence subsists throughout the motion. Under this assumption the problem is merely one of particle dynamics, of which the solution may be regarded as completely known. The comparison of calculations and observations shows good agreement in range and height when the shells are suitable and the total angle turned through by the tangent to the trajectory is less than, say, 50°. The calculated trajectory, however, is a curve lying in the vertical plane containing the original direction of projection, while the observed positions of the shells do not lie in this plane, but appreciably to the right of it when their axial spin is right-handed. This well-known departure from the original vertical plane is called *drift*, and converts the trajectory into a twisted curve. It cannot be accounted for on the original assumption

It is with these cases, in which particle dynamics fails to explain the observations—such as the drift, trajectories of large total curvature, and (as we shall see) initial motions—that we are mainly concerned here. For their study we must abandon the assumption that the direction of motion of the centre of gravity and the direction of the axis of symmetry coincide, and study the whole motion as a problem in rigid dynamics.

In order to do this we must, first of all, deter-

mine experimentally the complete reaction of the air on the moving shell when the directions of its axis and the motion of its centre of gravity no longer coincide. In such a case the angle between these two directions is called the *yaw*. Until recently the reaction on a yawed shell had never been studied experimentally. The necessary data, however, can be obtained by observation and analysis of the initial motion of the shell in the first few hundred feet after leaving the muzzle of the gun, for in this interval the axis of a shell oscillates periodically over an appreciable range of yaw.[1] The motion is a little complicated, and its interpretation is not yet completely worked out in terms of the reaction of the air. Moreover, a really satisfactory experimental method has not yet been devised. But a start has been made on the problem, and approximate values of the more important components have been determined.[2]

The somewhat crude experimental method so far used consists in firing a shell through a series of cardboard screens. The shape of the hole in the card determines the size and direction of the yaw at the instant of passing through the card. From such observations the motion of the axis can be plotted out against the time (if the velocity of the shell is known), and the period of its oscillations determined. The disturbing effect of the cards themselves can be determined by suitable control experiments and roughly estimated. Two specimen observed curves[3] traced out by a point on the axis of the shell relative to the centre of gravity are shown in Figs. 1 and 2. These two paths are strictly comparative, as the only difference between their circumstances is an alteration of the axial spin. The slowly spinning shell (Fig. 1) has oscillations of comparatively long period and large amplitude. These curves are closely analogous to the curves which represent the oscillations of a spinning top near its vertical position. They differ only in showing slight damping and variation of period.

Let us consider further this analogy between a shell and an ideal spinning top. The centre of gravity of the shell and the point of support of the top are analogous; so are the moments of inertia about these points and the axial spins. To the direction of motion in the case of the shell corresponds the vertical in the case of the top; to the disturbing couple due to the reaction of the air on a yawed shell corresponds the gravity couple on a displaced top. The analogy so far is practically exact; it is modified by the following facts:—

(1) That the centre of gravity is not a fixed point like the point of a top, for its velocity varies both in magnitude and in direction under the reaction of the air; it describes a helical curve, thus modifying the couple.

(2) That an appreciable frictional couple exists which, in conjunction with the helical motion of the centre of gravity, serves to damp out the axial oscillations completely.

(3) That, in addition to (1) above, the magnitude and direction of the velocity of the shell are steadily altered by gravity.

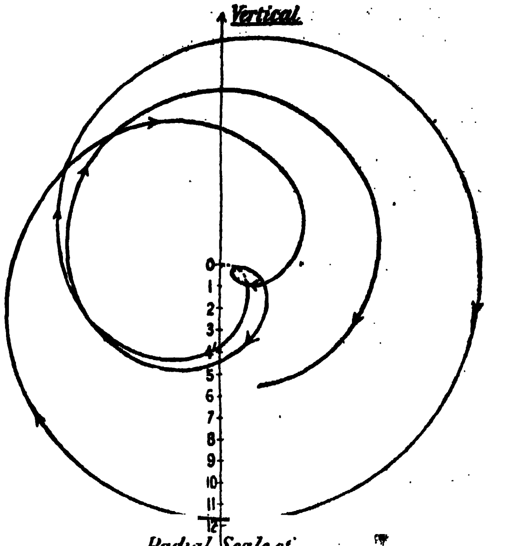

FIG. 1.—Observed path of the nose of a shell, muzzle velocity 1565 f.s. Rifling 1 turn in 40 diameters of the bore. Total time taken to describe curve shown 0.38 sec.

Experiments so far carried out have determined approximately the values of the couple analogous to the gravity couple for velocities from 900 f.s. to 2200 f.s. for two different shapes of shell, when the yaw is not too large. By determining these couples for various different positions of the centre of gravity, rough values of the resulting sideways thrust on a yawed shell were deduced.

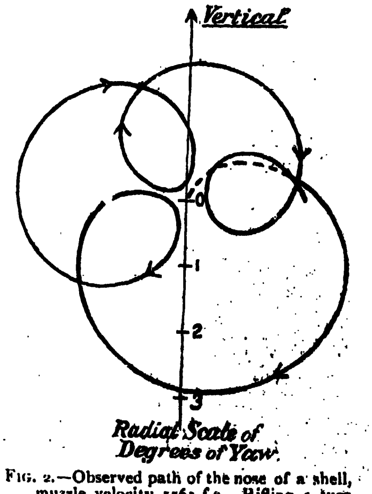

FIG. 2.—Observed path of the nose of a shell, muzzle velocity 1563 f.s. Rifling 1 turn in 30 diameters of the bore. Total time taken to describe curve shown 0.20 sec. [The scale of Fig. 2 is three times that of Fig. 1.]

[1] Such experiments are described in a forthcoming paper in the Royal Society Transactions by R. H. Fowler, E. G. Gallop, C. N. H. Lock, and H. W. Richmond.

[2] The forces on a model shell at rest in a steady current of air of low velocity can also be measured directly in a wind channel; the results are probably applicable to a shell moving at velocities up to 700 f.s.

[3] The observations were made for the Ordnance Committee at H.M.S. *Excellent*, Portsmouth.

The study of initial motions is intimately connected with the question of the *stability* of a spinning shell at zero yaw. The motion of a shell (or a top) is said to be stable if a small disturbance only produces a small maximum displacement from the position of symmetry, proportional to the disturbance. The condition of stability for small disturbances is the same in the two cases; it must be fulfilled in order that the shell may travel along its trajectory approximately at zero yaw as desired. A knowledge of the disturbing couple enables us to lay down how much spin is required to allow a reasonable margin of stability.

We have said that the usual approximation of motion at zero yaw is inadequate in the case of trajectories of large total curvature. The complete theory indicates that, under the effect of gravity (see (3) above), the yaw tends to attain a sort of equilibrium value which increases along the trajectory, and may reach 20° or more at the end of a sufficiently long arc. A study of initial motions with slightly unstable shells in which such values of the yaw can be realised experimentally will provide the material required for the proper discussion of such trajectories.

The following approximate theory accounting for the drift of a shell has long been known. Owing to the change of direction of motion due to gravity (see (3) above), a shell cannot continue to move steadily at zero yaw. The proper equilibrium state of affairs is attained when the yaw is just such as will enable the axis to keep pace with the changing direction of motion by precession about it. This equilibrium value of the yaw depends on the above-mentioned disturbing couple due to the reaction of the air, which may be determined by a study of the initial oscillations. The resulting yaw in ordinary cases is too small to alter seriously the range at any given time, and does not affect the height because the equilibrium position of the yawed axis lies in a plane which is always very nearly at right angles to the vertical plane containing the original direction of projection. It produces, however, the lateral deviation known as drift. This approximate theory leads to a formula for the drift depending on the ratio of the sideways thrust to the disturbing couple. With the values of this ratio recently roughly determined, the drift has been calculated by this classical theory, and compared with direct observations of the drift of similar shells. The observed and calculated values are in fair agreement, and there is no doubt that the classical theory is substantially correct.

In conclusion, it is perhaps worth mentioning that the interest in such investigations mainly arises from the fact that we can thus study the phenomena of motion through a compressible fluid at velocities both greater and less than the velocity of sound in the fluid. The investigation, however, has scarcely begun, and much work will be required before it is possible to describe adequately the complete reaction on a shell of given shape moving through air.

Obituary.

Prof. L. Doncaster, F.R.S.

LEONARD DONCASTER'S death from sarcoma at the age of forty-two has stopped a career of exceptional distinction. When I lately saw him, apparently in his usual health, presiding over his laboratory as the newly elected Derby professor of zoology at Liverpool, I had comfort in the thought that by his appointment a fresh centre of genetics was safely begun. Doncaster was a natural investigator. From his student days there was never a doubt as to the purpose of his life. The problems of biology were always in his mind. For him the materials were everywhere. Though circumstances led him into academic zoology, he was an excellent field entomologist and botanist, with a fair knowledge also of the domesticated forms. Latterly he became more and more drawn towards cytological methods, but he always kept in touch with the other lines, knowing that the next advance may begin anywhere.

Doncaster started at Naples with experiments on hybridisation of Echinoderm larvæ, which produced evidence of value as to the effects of temperature in modifying dominance; but many aspects of that vexed question remained, and still remain, obscure. He returned to England at the moment when the early struggles of Mendelism were acute. Though constitutionally predisposed to caution, he knew enough of the general course of variation and heredity to be in no doubt of the essential truth of the new doctrines, and undoubtedly his adhesion did much to spread confidence among his contemporaries. He at once joined in breeding work, and at various times experimented with many forms, particularly rats, cats, and pigeons. With insects of several orders he was especially successful. The seemingly more fundamental nature of microscopical work made it very congenial to him, and he always had a mass of cytological material on hand. These studies enabled him to take a prominent part in that comprehensive codification by which the confused and contradictory observations as to the sexes of parthenogenetic and other forms in the Hymenoptera and Hemiptera were ultimately reduced to order.

In the history of biology Doncaster's discovery as to the determination of sex in the currant moth (*Abraxas grossulariata*) will have a permanent place. From the Rev. G. H. Raynor, a fancier of the species, he learnt facts which suggested that the variety *lacticolor* was what we now call "sex-linked," being predominantly associated with females, as colour-blindness in man is with males. After verification and extension this mass of facts provided (1906) the first clear genetic proof of

sex-determination in the gamete, a discovery of astonishing novelty at that time, though now so familiar to us all that we have forgotten how hard it was to achieve. Being greatly struck with Wilson's cytological proof that many *male* insects are heterozygous for sex, and having himself proved that in Abraxas the female is in this condition, Doncaster devised a scheme in which both sexes are thus represented, dominance being attributed to the female gamete; but he afterwards accepted a simplifying emendation in which the male is taken to be homozygous. After this, finding a curious strain in which half the females produce daughters almost exclusively, Doncaster showed that these females generally had only fifty-five chromosomes instead of the normal fifty-six. By reasoning analogous to that afterwards used by Bridges in his famous paper on "non-disjunction," he attempted a cytological interpretation, though, as he admitted, the solution was imperfect, and the case is still mysterious.

Progress was also made with the paradox of tortoiseshell cats, known by fanciers to be almost exclusively females. Doncaster proved that tortoiseshell is the female heterozygote of orange and black, the corresponding male being orange; and in the course of wide inquiries he discovered the new fact that the rare tortoiseshell tom is often *sterile*. In his last paper he conjectured, not without probability, that, in view of Lillie's extraordinary discovery as to the free-martins of cattle, these males may owe their peculiarities to the intra-uterine influence of other embryos. Most of these subjects are discussed in his text-book, "The Determination of Sex," 1914. Just before his death Doncaster published an admirable "Introduction to the Study of Cytology," in which he declared himself with reservation a convert to the views of Morgan—a judgment which, from so critical an observer, must carry great weight.

His death will be cruelly felt. At a time when cytology is becoming a subject of primary importance, the loss first of R. P. Gregory and now of Doncaster leaves us bereft indeed.

Doncaster was one of the clearest-headed men I have known, and, being full of both enthusiasm and knowledge, he taught extraordinarily well. In Cambridge he served in various capacities, and was for four years in the University of Birmingham. As Prof. Herdman has written, his death is "nothing less than a calamity to Liverpool University." Doncaster was slight in figure and of a nervous temperament, feeling and thinking of everything with intensity, though nevertheless a fluent speaker. He came of a Quaker family, being the son of Samuel Doncaster, manufacturer, of Sheffield, in whose beautiful garden he developed his love of plants. Educated at the Friends' School at Leighton Park, Reading, he went up as a scholar to King's College, Cambridge, of which he afterwards became a fellow. He married in 1908 Dora, daughter of Walter Priestman, of Birmingham, and leaves three children.

We did not speak of such matters, but it was known to his friends that Doncaster had religious instincts strongly developed. The years of the war were to him more hateful even than to most thoughtful men. He held the Friends' attitude of the unlawfulness of war, but, feeling that alternative service was a duty, he gave up his researches and qualified as a bacteriologist, working in the 1st Eastern Hospital, Cambridge, and afterwards in the Friends' Ambulance Unit at Dunkirk.

W. BATESON.

MR. JOHN W. HYATT, of Newark, New Jersey, whose death is reported at the age of eighty-two, was the inventor of celluloid. He was a printer by trade, and was using collodion in the course of his work when he accidentally overturned a bottle, and the idea of celluloid came to him from watching the collodion solidify. He took out 250 patents in all, a large majority of which had an important bearing on manufactures. They included a billiard-ball composition, a roller bearing, a system of purifying water for domestic use, a sewing machine capable of sewing fifty rows of lock-stitches at once, a machine for extracting juice from sugar cane, and a new method of solidifying American hardwoods. In 1914 Mr. Hyatt was awarded the Perkin medal of the New York Society of Chemical Industry.

WE much regret to see the announcement in the *Times* that PROF. AUGUSTO RIGHI, For. Mem. R.S., died suddenly at Bologna on June 8 at seventy years of age.

Notes.

THE list of honours conferred in celebration of the King's Birthday includes the following names of men associated with scientific work:—*Irish Privy Councillor:* Mr. H. T. Barrie, Vice-President, Irish Department of Agriculture. *K.C.B.:* Sir A. W. Watson, president of the Institute of Actuaries. *C.B.:* Mr. A. W. Flux, Assistant Secretary, Board of Trade. *Baronet:* Mr. P. J. Mackie, who financed the Mackie Anthropological Expedition to Uganda and other expeditions. *Knights:* Prof. F. W. Andrewes, F.R.S., pathologist at St. Bartholomew's Hospital; Capt. D. Wilson-Barker, captain-superintendent of the training-ship *Worcester*, and past-president of the Royal Meteorological Society; Dr. J. C. Beattie, Principal of the University of the Cape of Good Hope; Mr. W. B. M. Bird, founder of the Salters' Institute of Industrial Chemistry; Dr. H. H. Hayden, Director of the Geological Survey of India; and Prof. J. B. Henderson, professor of applied mechanics, Royal Naval College, Greenwich. *C.I.E.:* Mr. C. M. Hutchinson, Imperial Agricultural Bacteriologist, and Mr. R. S. Pearson, Forest Economist, Research Institute, Dehra Dun. *K.B.E.:* Dr. J. Dundas-Grant, eminent aural specialist; Dr. J. C. Stamp, distinguished economist; and Col. W. Taylor, ex-president of the Royal College of Surgeons in Ireland. *Companions of the Imperial Service Order:* Mr. R. B.

Newton, assistant in the Department of Geology, British Museum (Natural History); Dr. W. Eagle Clark, keeper of Natural History Department, Royal Scottish Museum, Edinburgh; and Mr. R. Duncan, Staff Officer, Veterinary Branch, Department of Agriculture and Technical Instruction, Ireland.

THE following decorations have been conferred upon scientific workers in recognition of valuable services rendered during the war, and the King has granted permission to wear them:—Conferred by the King of Italy—Order of the Crown of Italy: *Chevalier:* Mr. H. D. Roberts, director of Public Library, Museums, and Fine Art Galleries, Brighton. Order of St. Maurice and St. Lazarus: *Officer:* Sir Douglas Mawson, Dr. T. M. Lowry, F.R.S., and Prof. P. F. Frankland, F.R.S. Conferred by the King of the Belgians—Order of the Crown: *Grand Officer:* Sir Alfred Sharpe. *Commander:* Prof. W. Somerville. *Officer:* Dr. E. J. Russell, F.R.S. *Chevalier:* Mr. C. E. Fagan, Mr. A. R. Hinks, F.R.S., secretary of the Royal Geographical Society, and Mr T. McRow. Order of Leopold II.: *Commander:* Dr. W. R. Dunstan, F.R.S., director of the Imperial Institute, and Prof. G. H. F. Nuttall, F.R.S.

IT is announced in *Science* that the U.S. National Academy of Sciences has recently elected the following foreign associates:—Frank Dawson Adams, McGill University; Marie Ennemond Camille Jordan, Collège de France; François Antoine Alfred Lacroix, Musée d'Histoire Naturelle, Paris; Heike Kamerlingh Onnes, University of Leyden; Sir David Prain, Royal Botanic Gardens, Kew; and Santiago Ramon y Cajal, University of Madrid.

MR. O. F. BROWN, assistant inspector of wireless telegraphy in the Post Office, has been appointed Technical Officer to the Radio Research Board, which has been formed recently under the chairmanship of Admiral Sir Henry Jackson, in connection with the Department of Scientific and Industrial Research.

SIR W. J. POPE, F.R.S., was elected an associate of the section for the mathematical and physical sciences of the Académie Royale de Belgique on June 5.

COL. H. G. LYONS has been appointed director and secretary to the Science Museum, South Kensington, in succession to Sir Francis Ogilvie, who has been transferred to the Department of Scientific and Industrial Research.

PROF. FLINDERS PETRIE in *Ancient Egypt* (1920, part ii.) describes a remarkable statue of ebony 27 in. high. "The pose of the standing position is more thrown back than in the Old Kingdom, from the waist upward. The head has had inlaid eyes, now missing. The expression is marvellously vigorous and full of vitality, and it differs from other Egyptian figures not only thus, but also in the type. The very wide jaw, short chin, and high cheek-bone have hardly a parallel in other statues. It is clearly one of the great masterpieces, and of a rare style of work." It is stated to have come from the Eleventh Dynasty temple at Deir-el-Bahri, and may represent one of the Mentuhetep kings, but the provenance is so uncertain that it is difficult to identify it. "When workmen are not well rewarded for the objects found, much is taken away without any record of the original place and connection. If we knew the position to which the figure belonged, the burial chamber, the royal shrine, the family shrines, or elsewhere, we might have fixed the historic value of one of the most striking portraits known from Egypt."

MR. J. BRONTÉ GATENBY, whose papers on the cytoplasmic inclusions of the germ-cells have formed such a conspicuous feature of the *Quarterly Journal of Microscopical Science* during the last few years, contributes to the last number of that journal (vol. lxiv., part 3) a valuable account of the modern technique of cytology, which, taken in conjunction with his recently published paper on "The Identification of Intra-cellular Elements" (Journal of the Royal Microscopical Society, 1919), should prove of great use to students of microscopical zoology. These papers will place within reach of all many of the numerous modern refinements of technique which are indispensable to future progress, and the use of which bids fair to increase to a very great extent our knowledge of cell morphology and development. We are glad to learn that the author has also undertaken to edit a new edition of that classical and widely appreciated work, Bolles Lee's "Microtomist's Vade Mecum."

IN sending the Report of the Curator of the Somerset County Museum, Taunton Castle, for the year ended September 30, 1919, Mr. H. St. George Gray directs our attention to three graphs showing (1) the annual increase in membership of the Somersetshire Archæological and Natural History Society since 1880; (2) receipts from entrance fees to the museum for the years of this century; (3) fluctuations in the number of visitors during the same period. We are not prepared to admit offhand that this is the first application of graphic curves to society and museum statistics, but the results are undoubtedly illuminating, and, in this case, raise interesting questions for the consideration of those directing the policy of the museum. If such charts, with more frequent time-intervals, were prepared on a consistent plan by all institutions of the kind, their comparison would bring new light to social and economic studies.

THE *Museums Journal* for April–May prints a weighty report on the relation of museums to the advanced student, presented to a British Association Committee by a strong sub-committee. It is claimed that the interests of the serious student should not be sacrificed to those of the general visitor. The needs of the researcher, university student, private student, and collector are considered, and practical recommendations are based on experience. In view of the proposed site of London University, it is interesting to find the report urging closer co-operation between universities and museums. "The student may fairly be asked to help by doing some curatorial work. . . . The museum will profit by the improved arrangement of the objects, and the student will learn how to utilise specimens and how to discover the relevant literature." The student should be supported by "a

system of scholarships, held on the double condition of carrying out in the museum research work and curatorial work satisfactory to the professor and the curator respectively.''

An interesting addition to the literature on the subject of the relationship between light and plant-growth appeared recently in the *Journal of Agricultural Research* (vol. xviii., No. 11, March, 1920). In this paper W. W. Garner and H. A. Allard discuss the effect of the relative length of day and night, and of other environmental factors, on growth and reproduction. Their results show that the relative length of the day is a factor of the first importance in plant growth, particularly with respect to sexual reproduction. The effect on sexual reproduction of environmental factors such as temperature, water-supply, etc., seems to be simply one of acceleration or retardation so long as these factors are within a normal range. The seasonal length of day, however, may actually initiate the reproductive processes or inhibit them, according as to whether the given length of day is favourable or unfavourable for the particular species. If the length of day is unfavourable to sexual reproduction, but favourable to growth, then vegetative development is continued indefinitely; but if the length of day is favourable to both reproduction and growth, then the period of sexual reproduction is extended. The seasonal range in the length of day is therefore an important factor in plant distribution, and, moreover, the relation between length of day and reproduction emphasises the great necessity for seeding crops at the proper time.

In Publication No. 295 of the Carnegie Institution of Washington, entitled "A New Type of Hereditary Brachyphalangy in Man," Messrs. Otto L. Mohr and Chr. Wriedt illustrate the heritability of a trivial character for six generations. The character is a symmetrical shortening of the second joint of the second fingers and toes which recurred without any break for six generations within a Norwegian family, some members of which emigrated to America. Without exception the peculiarity was restricted to the particular phalanx mentioned, the hands and feet being in other respects quite normal. There was no associated shortness of stature. The anomaly manifests itself under two distinctly different somatic types, one "slightly" shortened and generally overlooked by the affected individuals, the other "much" shortened and very striking. No case of an intermediate condition was observed. The brachyphalangy is inherited as a dominant, not as a sex-linked, character. The numerical ratio between the affected and unaffected individuals in the offspring of brachyphalangous members of the family is in accordance with the theoretical Mendelian expectation. All the brachyphalangous individuals are heterozygous for the gene in question, with one possible exception. The material includes a case of identical twins, both showing the same type of brachyphalangy. A genetic explanation of the occurrence of the "slightly" shortened and the "much" shortened types is suggested. The authors are to be congratulated on their careful working out of an interesting case.

On Friday, June 4, the Association of Economic Biologists and the Imperial Entomological Conference held a joint meeting at the Rothamsted Experimental Station, Harpenden. The greater part of the day was devoted to an examination of the field experiments which were demonstrated by Dr. E. J. Russell and Dr. Winifred E. Brenchley. The park grass plots have been under grass for some centuries; it is not known that seed has ever been sown, and at the beginning of the experiments (1856) the herbage on all the plots was apparently uniform. The twenty-three plots are each manured differently, the same treatment being maintained year after year, and the southern half of each plot is limed. The difference in the vegetation on the several plots is now most remarkable, and, quite apart from the great and immediate practical value of the experiments, they are an ecological demonstration of the very first importance. The Broadbalk wheat field is perhaps the most famous single field in the world. Here wheat has been grown continuously since 1843, the eighteen plots receiving different manurial treatment which has been maintained year after year. The knowledge already yielded by Broadbalk has served almost to revolutionise the earlier ideas concerning the growth and needs of the wheat-plant and the nature of the soil, and the attention now being concentrated upon it by physicist, chemist, statistician, protozoologist, entomologist, mycologist, and algologist should continue the good work begun by Lawes and Gilbert, and so ably sustained by Sir Daniel Hall and the present director. After tea Dr. A. D. Imms opened a discussion on "Tropisms," giving a brief account of his own investigations on chemotropism, and relating these to the general theory of tropisms formulated by Loeb. A paper specially contributed by the latter author was read, and Dr. Tillyard, of New Zealand, Mr. E. E. Green, Dr. Williams, Sir J. C. Bose, Mr. W. B. Brierley, and Prof. Neilson Jones took part in the discussion that followed.

An interesting case of extreme differentiation of types of igneous rock, in which the whole series is accounted for by gravitational separation, is described concisely by Mr. H. C. Cooke in "The Gabbros of East Sooke" (Canada Geol. Survey, Museum Bull. No. 30, 1919). In view of the use of the mineral name "anorthose" for soda-microcline, objection may be taken to the term "anorthosite" for rocks with felspar akin to anorthite.

Prof. G. Cesàro sends us a paper on minerals from Monte Somma and Vesuvius, which is of interest as having been prepared for issue in the Bulletin de la Classe des Sciences of the Académie royale de Belgique in 1914, and actually circulated by its author in 1919. Prof. Cesàro has meanwhile, by the stress of war, become personally known to a circle of British mineralogists, who will maintain cordial relations with him despite his return to his own country. As an appendix to the paper Prof. Cesàro describes an apatite from Cornwall as having a low birefringence, and therefore a high fluorine content, and in dealing with similar apatite from Vesuvius he quotes from his previous work the relations between the fluorine present and certain angles of the crystals.

BULLETIN No. 22, part i., of the Geological Survey of New Zealand, on the limestone resources of the country, by Mr. P. G. Morgan, is really a treatise on limestone and its uses, illustrated from occurrences in New Zealand. It is thus exactly suited to local requirements; but both it and its successor on the phosphates will be welcomed in a much wider field. Attention is well given to the use of lime and of ground limestone on the land. The literature to be consulted is wide, but we note that all the papers named as of a general character are of American origin. We thus miss the work of Messrs. Hutchinson and MacLennan at Rothamsted, published in the *Journal of Agricultural Science* in 1915. Mr. J. A. Hanley's account of his experiments with various limes in Yorkshire (Journ. Soc. Chem. Indust., 1918) is probably too recent for inclusion, since communications have been disturbed by war; but for some years past there have been indications that authors and publishing bodies in the United States have been more mindful than ourselves of libraries in the Pacific region. This should be a reminder for Britons, who are the true begetters of the enterprising island folk.

THE Executive Committee of the Advisory Council of Science and Industry of the Commonwealth of Australia has issued the third and concluding part of an exhaustive report by Dr. F. L. Stillwell upon the factors influencing gold deposition in the Bendigo goldfield. As is well known, the mode of occurrence of the gold reefs in this field is quite unique, and its peculiarities have given rise to much discussion, so that the thorough investigation here presented should be of great interest to all students of mineral deposits. The general conclusions arrived at are that the form of the reefs is due primarily to that of the original fracture through which the depositing solutions have percolated; that all the large and important reefs have been in some way associated with faults, the latter being generally contemporaneous and connected with the folding of the rocks, the faults having given rise to a network of fractures which afforded a passage to the mineralising solutions; and that the deposition of the gold from these solutions has been brought about in three ways: (1) Precipitation from the auriferous solution; (2) crystallisation from a supersaturated solution; and (3) crystallisation from solutions the supersaturation of which is due to decreasing temperature after the main portion of the gold has been precipitated. The first of these is the most important method of deposition, and appears to be closely connected with the presence of carbonaceous matter.

IN his address to the Royal Geographical Society at the anniversary meeting on May 31, Lt.-Col. Sir Francis Younghusband pleaded for a wider outlook in geography and freedom from a strictly utilitarian viewpoint. A knowledge of the beauty of the earth may be legitimately included within the scope of geographical science. Beauty of scenery in many instances is the most noteworthy characteristic of a country and its most valuable asset. Advertisements of tourist organisations, railway and steamship companies, and even emigration departments, bear constant witness to the importance of this aspect. Moreover, natural beauty is inexhaustible, while mineral wealth is limited and agricultural productivity not unbounded. Sir Francis Younghusband contended that the geographical knowledge of a country was incomplete without a knowledge of its beauty, and that by this means alone can the geographer gain a sense of the earth "as live, supple, sensitive, and active." Continuing, he pointed out that there should be less hesitation in accepting this principle when it is realised that natural beauty affects the movements of man, and that man is having an increasing effect on natural beauty, often, but not always, with disastrous results. This relationship between man and the beauty of the earth is one of which geography should take as much cognisance as it does of the relationship between man and the productivity of the earth. The knowledge of beauty must be carefully gathered. Careless snapshots and shallow rhapsodies in guide-book style are unsatisfactory. We require the best photographs as well as paintings and accurate descriptions of literary merit. The artist both in pencil and in words is essential in geographical work.

IN the *Meteorological Magazine* for May a notice is given of the circulation of forecasts by wireless telegraphy from collective weather reports for London and south-east England. Hourly reports of meteorological information prepared by the Forecast Service of the Meteorological Office are sent out from the wireless station at the Air Ministry. The message is given in a code form, which is practically the same as that prescribed in Annex G of the "Convention relating to International Air Navigation," Paris, 1919. The forecasts, which are being issued eight times a day, are based on observations taken about half an hour before the time of issue. Detailed explanation of the code can be obtained on application at the Meteorological Office. A new device is also mentioned for making the meteorological reports rapidly available to the public. A large weather map is exhibited daily at the Air Ministry in one of the front windows on the ground floor of Empire House, Kingsway. All the principal reporting stations in the British Isles, as well as a few neighbouring Continental ones, are marked on the chart, which is on the Mercator projection, and is 10 ft. high and 6 ft. wide. The information on the chart is changed at about 3h., 8h. 30m., and 14h. 30m. G.M.T., the data exhibited referring to observations made at 1h., 7h., and 13h. G.M.T. The exceptionally wet character of April is well shown in the Thames Valley Rainfall Map, where upwards of 5 in., and in places more than 6 in., of rain occurred during the month over the western portion of the valley. Districts with less than 3 in. are rare, and almost entirely confined to the neighbourhood extending from London to the mouth of the Thames. In England and Wales the general rainfall for April was 204 per cent. of the average.

FOR many years the utilisation of the water-power of the Rhone has attracted attention in France. The shortage of coal has renewed interest in the problem,

which is now on the road to solution. The Chamber of Deputies has taken the matter in hand, and agreed to proposals which now await consent by the Senate. According to an article by M. M. Fourniols published in the *Revue générale des Sciences* for May 15, the plan is to divide the river into six sections, to be managed separately or preferably by a single body. Concessions are to be for seventy-five years' duration, and will be helped by State loans. Besides the utilisation of water-power, the project embraces the improvement of navigation, the creation of river ports, and the construction of irrigation works. At present the conditions are not favourable for navigation, but the recently opened canal from Marseilles to Arles opens a new vista of possibilities in cheap river connections with the sea. It is proposed to erect a number of power stations between Genissiat, near the Swiss frontier, and Comps, near Tarascon. Genissiat with 200,000 h.p. will be the largest, and will probably supply power to Paris. Other important stations will be near Lyons, Valence, Montelimar, and Mondragon. A form of dam and locks is projected which will interfere as little as possible with navigation.

IN an article in the *Revue Scientifique* for May 22 M. A. de Gramont de Guiche, president of the council of the Institute of Optics of France, describes the arrangements made for the first session of the institute, April to July, of the present year. The institute is divided into three sections: (1) A school of higher studies intended to provide the training requisite for the specialists in the subject; (2) a laboratory for research and practical instruction; and (3) a school for the training of the workmen and craftsmen both in glass- and in instrument-making. At the opening of the course on April 12 M. Jobin, one of the members of the council, described in detail the objects of the institute and the steps that were being taken to carry out those objects, and Dr. Dunoyer gave the first lecture of a course on optical instruments. Other lecture courses are provided on "The Calculation of Optical Systems," "Spectroscopy," "Glass: Its Nature and its Applications," "The Applications of Polarised Light," "The Microscope," and "The Properties of X- and γ-Rays." The fee for the session is 150 francs, and, although no one is excluded, it is pointed out that to profit as much as possible from the course students should have a fair knowledge of mathematics.

IN a paper published in the *Mathematical Gazette* for 1919–20 Dr. S. Brodetsky, reader in applied mathematics in the University of Leeds, brings forward a graphical treatment of differential equations as of special value in certain cases which are not soluble by the usual analytical methods and as of general value for purposes of instruction. There is justice in his view that the average student of mathematics regards the usual methods of solution as a series of tricks which he learns to apply with more or less success to such equations as are presented to him. A graphical treatment cannot fail to be of great value in teaching the meaning of differential equations and in giving the student confidence in their use. The paper contains numerous examples, and illustrates the meaning of singular solutions, cusp loci, etc. Not the least interesting example is the solution of the equation

$$\frac{dy}{dx} = -\frac{x}{y} + (x^2+y^2)^{\frac{1}{2}},$$

which occurred in discussing the motion of a plane lamina moving in air under the earth's attraction—one of the simple types of aeroplane motion. The equation was insoluble by any of the standard methods, but easily soluble graphically.

DURING the war considerable quantities of acetone were prepared by the fermentation of starchy material. Hitherto, however, no investigation of the mechanism of this fermentation has been described, and Messrs. J. Reilly, W. J. Higginbottom, F. R. Henley, and A. C. Thaysen publish in the April issue of the *Biochemical Journal* an account of a quantitative examination of the process. These authors find that the fermented mash contains varying proportions of acetic and butyric acids, the ratio of the latter to the former increasing with the increase (during fermentation) in the acidity of the mash and reaching a maximum at the stage of greatest acidity. Not until the latter stage is reached are appreciable quantities of acetone and *n*-butyl alcohol produced. With the production of "oil" the ratio of butyric to acetic acid diminishes, and finally the mash contains an excess of acetic acid. During the period of the increase of acidity of the mash the rate of gas evolution rises steadily for some time, then becomes constant; and as the acidity falls the rate of gas evolution rises quickly to a maximum, and then falls rapidly until the end of the fermentation. The gas consists of hydrogen and carbon dioxide in a proportion varying from 3 : 1 at first to 2 : 3 at the latter part of the fermentation. It is extremely probable that acetic and butyric acids are not the only acids formed, and evidence is given of the presence of an acid less volatile in steam. Lactic acid results from the type of infection most frequently observed. If the fermentation is carried out in the presence of calcium carbonate it proceeds as far as the point of maximum acidity, but the production of acetone and *n*-butyl alcohol is almost entirely suppressed.

IN the *Wiener Denkschriften* (Math.-Naturwiss. Kl., Bd. 96, pp 671–750, 1919), [illegible] A. Defant continues his important researches on [illegible] in landlocked and border seas, bays, and chann[illegible] after a theoretical discussion of the influence of friction against the ocean-bed in channels, he deduces an average value of the coefficient of skin friction from a consideration of the tides in the Gulf of Suez and in certain lakes which exhibit seiches. He then enters upon a careful detailed study of the tides in the English Channel, using a step-by-step numerical method for the solution of the differential equations of the tides between successive cross-sections of the Channel. He thus succeeds in demonstrating the truth of a conjecture made long ago by Airy to the effect that the complicated tides of the Channel are governed mainly

by the definite tidal oscillations of the Atlantic Ocean and the North Sea at the two ends of the Channel; this view had been contested by Börgen, but the consequences of the view were misinterpreted by the latter. Dr. Defant shows that not only the co-tidal lines and tidal ranges, but also the phase and speed of the tidal currents in the Channel, can be explained on the basis of Airy's ideas, taking surface friction at the channel-bed into account, and also the rotation of the earth. He finds that the latter affords an explanation of why the tidal range on the French coast of the Channel is greater than that on the English coast. For the sections of the Channel near the east opening into the North Sea the calculations cannot be executed with the accuracy elsewhere obtained, owing to the approximation of the ocean-tidal period to the free period of lateral oscillation across this broad part of the Channel. But even here the chief features can be derived by interpolation, and throughout the remainder of the Channel all important features of the complex Channel tides receive satisfactory theoretical explanation.

THE paper read by Gen. Squier to the U.S. National Academy on April 27 on "Multiplex Telephony and Telegraphy over Open-circuit Bare Wires Laid in the Earth or Sea" has excited great interest amongst radio-telegraphists, who find it difficult to make out whether we are on the eve of important developments or not. Gen. Squier has established communication for a distance of three-quarters of a mile over the Potomac River by means of a bare No. 12 phosphor-bronze wire laid directly in the water. The transmitter consisted of an electron tube oscillator, which produced a current of about 270 milliamperes at a frequency of 600,000. At the receiving end of the line an electron tube and a six-stage amplifier were used without any earth connection. With this arrangement good tuning could be obtained at either end of the line, and satisfactory telegraphic and telephonic transmissions secured by means of the bare wire immersed in fresh-water. In another experiment telegraphic and telephonic transmission were obtained between two stations three-quarters of a mile apart by means of a No. 16 copper wire buried in the earth to a depth of about 8 in. It will be seen that if the method develops satisfactorily it will have commercial possibilities. The best Atlantic cable cannot operate at a frequency greater than 10 per second, and 80 volts is the highest voltage that can be applied to work it. There is scope, therefore, for development in submarine telegraphy. Gen. Squier suggests that experiments should be made with bare wires in sea-water to determine what arrangement will give the best results. He points out that with this method there will be no distortion of the signals, and so there is no limit to the distance of transmission, and the receiving apparatus will be comparatively simple. It is also possible to transmit simultaneously several signals, both telephonic and telegraphic, over the same wire by using different frequencies. The method is an attractive one, and seems to have arrived at the stage where commercial research can usefully be started.

Our Astronomical Column.

PHOTOGRAPHS OF THE BRORSEN-METCALF COMET.—The *Astrophysical Journal* for March contains some photographs of this comet taken by Prof. Barnard on 1919 October 5, 6, 20, and 22. The tail is shown as fully 6° long, composed of several narrow straight streamers forming a fan. They radiate from a point somewhat behind the centre of the head. About October 20 the comet discarded its tail, and formed a new one inclined 12° to the old. Prof. Barnard notes that similar phenomena have been observed in Borrelly's comet, 1903 July 24, in Morehouse's comet on several dates in 1908, and in Halley's comet on 1910 June 6 (probably also in April).

In each case the new tail appears to move out faster than the rear portion of the old tail. Prof. Barnard conjectures that the latter is formed of larger particles, the motion of which would be slower.

He has combined successive cometary photographs in the stereoscope in the endeavour to determine the configuration of the tail in three dimensions. Care is, of course, required to distinguish true stereoscopic effects from spurious ones. It is stated that the tail of Morehouse's comet on October 15, 1908, resembled "part of an open sack, or a partly opened scroll."

THE PLANETARY FAMILIES OF COMETS.—The report of the nineteenth meeting of the American Astronomical Society contains a paper on this subject by Prof. H. N. Russell. He notes that the orbits of the six comets of the Neptune group all pass considerably closer to the orbits of Jupiter and Saturn than they do to that of Neptune. His first conclusion was that these comets had been captured not by Neptune, but by Jupiter. He analysed the orbits of the periodic comets with the following result:—

Thirty-six comets on his list have periods of less than ten years. The orbits of all these, except Encke's, pass within 0·65 of Jupiter's orbit, while seventeen of them pass within 0·15 of it.

Thirty-one comets have periods between ten and one thousand years. Of these, seven pass within 0·5 of Jupiter's orbit, five within the same distance from Saturn's orbit, and two within this distance from Uranus's orbit, the nearest approach to Neptune's orbit being 1·22.

Prof. Russell has calculated the proportion of the thirty-one comets that would pass within 0·5 of each orbit on the hypothesis of chance approach, and finds that it is six for Jupiter, three for Saturn, one and a half for Uranus, and one for Neptune. Hence he concludes that the observed figures give little evidence of capture by any of the planets.

There is, however, a point not noticed by Prof. Russell, which is that the periods under a century range themselves into four definite groups, the mean period of each group being about 0·4 of that of one of the giant planets. This gives strong ground for postulating a connection with these planets. Since Halley's comet has been observed for more than two thousand years, there is no difficulty in assigning to it a life dating back to the time when its orbit intersected that of Neptune. The longer the period of a comet the less frequent are the occasions when it is subject to serious disruptive influences, and consequently its disintegration is likely to be less rapid. It appears to the writer of this note that Proctor's suggestion that the periodic comets are the products of eruptions from the giant planets deserves more attention than it has generally received.

The Thunderstorms of May 29 and the Louth Disaster.

THE last week of May was marked by hot weather all over the country and by numerous thunderstorms, which culminated in the notable downpours of rain which occurred on Saturday, May 29. The highest temperatures were reported on Tuesday, May 25, when 82° F. was reached in London and the Thames Valley. In London the magnificent cumulus clouds made a fine spectacle, but it was further north, in the neighbourhood of Luton, that thunderstorms occurred. Paris suffered from a severe storm on the same day.

On Wednesday, May 26, when an area of comparatively low pressure extended across England and Ireland, there were thunderstorms in London and in other parts of the country during the afternoon. The rainfall in the west of London was exceptionally heavy. The area affected was somewhat sharply outlined on the west. At Hammersmith the roads were flooded and wood pavements burst up by the water, but at the Meteorological Office, a couple of miles away, only 2 mm. of rain fell. At Uxbridge 33 mm. fell in half an hour.

The distribution of pressure remained irregular, but lower over the British Isles than over neighbouring countries, and on Friday evening a "low," which appears to have originated over the South of France, began to deepen and to move northward. The map for 7h. G.M.T. on Saturday, May 29, indicates the depression by the isobar 1012·5 mb. over the Bristol Channel. At 13h. pressure was below 1012 mb. over the Midlands. By 18h. it had fallen to 1009 mb. in the same region. On Sunday morning the depression was over the North Sea, and by the evening, when it had deepened to 1004 mb., it was centred at the Shetlands.

The rainfall on May 29 was insignificant in the South of England, but falls of half an inch or more were general from Nottingham northwards. The exceptional falls in Lincolnshire and Lancashire occurred before the northward passage of the trough of lowest pressure. As to the downpour in Lincolnshire, to which the damage and loss of life at Louth are to be attributed, records are available from Hallington, in the valley west-south-west of the town, and from Elkington Hall, on the hills to the north-west. In each case the measurement was about 120 mm. in two hours, giving a mean rate of fall of 1 mm. per minute. According to newspaper reports, 100 mm. fell at Horncastle, twelve miles south-south-west of Louth.

The area with an exceptionally heavy rainfall included Bucknall, sixteen miles south-west of Louth, with a total fall of 54 mm.; at Lincoln, twenty-four miles away, the fall was 52 mm.; and at Spurn Head, to the north, it was 35 mm. The boundary of the area of heavy rain is marked by 34 mm. at Cranwell and 12 mm. at Fulbeck, these places being about four miles apart on either side of the Ermine Street, south of Lincoln. At Skegness only 12 mm. fell. There were two thunderstorms in the afternoon, both carried westward by the wind on the north side of the cyclone. One was [illegible] Skegness at 13.15 G.M.T., and at Lincoln at 14.30. The other, which was the more severe, moved m[illegible] slowly, passing Skegness at 16h. and Lincoln [illegible] 18.30 and 19h.

The [illegible] disaster seems to have been associated with [illegible]er storm. From the evidence at the inquest [illegible] witness from Benniworth, a village on the far [illegible] of the Wolds, in the Bain Valley, it appears that after a little rain between 13h. and 14.15 the weather cleared, but that at 14.30 the rain suddenly poured so fast that the house-pipe could not carry it. "In a moment the fields were at least 8 in. deep in water. I saw a huge cloud in the shape of an egg which kept twisting round. There were three flashes of lightning, very vivid and very shocking. One seemed to pierce through the cloud, and immediately afterwards the cloud seemed to come earthward."

Examination of the ground by the deputy coroner indicated that the heavier rainfall had been on the north side of the line from Louth to Lincoln, and that it was more severe higher up the valley than at Hallington, where the rain-gauge, which measured 120 mm., was situated. It is likely that the 120 mm. is a fair average for the fall over the basin of the Lud above Louth. This basin contains three or four brooks which unite above the town and drain an area of about 20,000 acres. The Wolds are chalk hills, however, and no doubt the greater part of the normal drainage is underground. This may account for the absence of any provision for the passage of flood-water, but much of the ground slopes at about 100 ft. to the mile, so that water would run off rapidly. Rainfall at the rate [illegible] mm. per minute over an area of 80 sq. km. would feed a stream 5 metres deep and 100 metres wide rushing along at 160 metres a minute, and the Lud does not appear to have reached such a magnitude as this. The town seems to have been singularly fortunate in escaping floods in the past, as a rainfall of even one-quarter of that on the present occasion could scarcely have found its way through the narrow bridges of the town.

With regard to the heavy falls in Lancashire, we are so fortunate as to have the autographic record from the rain-gauge at Leyland, to the south of Preston. The total fall for the twenty-four hours, 9h.–9h. May 30–31, is about 80 mm., "the like of which the proverbial oldest inhabitant cannot remember." The heaviest downpours were from 16.30 to 17h. and from 17.55 to 18.15. In the latter interval of twenty minutes no less than 40 mm. were recorded. The more dramatic exploits of the flood-water due to this storm appear to have been to the north of Preston, where the main line of the London and North-Western Railway was interrupted by the destruction of the embankment near the crossing of the River Brock. In spite of the long duration of the rain at Preston, the fall at Blackpool, fifteen miles to the west, amounted to only 5 mm. in the twenty-four hours.

Annual Meeting of the British Science Guild.

THE annual meeting of the British Science Guild was held in the Goldsmiths' Hall on Tuesday, June 8, the chair being taken by Lord Sydenham, president of the guild.

In his address on "Science and the Nation" the president referred to the strike evil as one of the great industrial problems of the day. The moulders' strike had seriously affected many industries; loss in coal had reached 50,000,000 tons a year as compared with 1913, with serious consequences to the export trade. The evil was due partly to an abnormal state of mind arising from the war, but was originally fostered by the industrial changes of the last century, namely, the general use of machinery, rendering labour monotonous and leaving less room for the individual skill of the craftsman, and the formation of large companies, whereby the personal touch between master and man was lost. Capital unduly concentrated in a few hands might lead to tyranny. This country needed a wider distribution of capital. Labour and capital must be reconciled, and science must find an

antidote for the deadening influence of the machine. In the latter portion of his address Lord Sydenham emphasised the importance of a more general knowledge of science, especially amongst members of the Government and the Civil Service, and alluded to the efforts made by the Guild in the dissemination of scientific knowledge and methods. He concluded by quoting Goethe's saying that "there is no more dreadful sight than ignorance in action."

Lord Sydenham then introduced the president-elect, Lord Montagu of Beaulieu, who delivered an address on "Some National Aspects of Transport," and afterwards occupied the chair. Lord Montagu remarked upon the growing difficulties of railways, which, although subsidised by the State, were working with a diminishing margin of profit owing to the vast increases in cost of materials and in wages. Some of the largest tramway systems, such as the L.C.C. in London, were incurring actual loss, and a general increase in fares and rates seemed inevitable. Some economies might be achieved by more scientific methods of handling traffic and the elimination of competition, but the saving from this source appeared relatively small. The possibilities of road transport, therefore, assumed importance. Already the comparative cheapness of short-distance road-borne traffic had deprived the railways of much revenue. Existing roads, however, were unfitted to bear very heavy mechanical traffic. On a tar-macadam road the tractive force was 40–45 lb. per ton, three times the force on rails, and on bad roads up to 100 lb. per ton may be needed. In the pre-railway period roads carrying metal tracks 2 ft. wide were constructed for carts carrying coal, minerals, etc. It might be feasible to lay such a plateway from London to Birmingham with a tractive force of only 20 lb. per ton. The cost of a double track would be about the same as for a single line of railway, as gradients up to 30 : 1 could be used. The cost of operation would be on a smaller scale than on railways, and goods could be delivered direct from door to door. The idea could be extended to other large towns, and it was conceivable that overhead roadways, for the exclusive use of fast-running vehicles, might be made from the suburbs. The creation of such routes would lead to a material increase in the value of property through which they passed, and part of the cost might be met by a local transport benefit tax, applied in such cases.

Lord Montagu also referred briefly to other possible developments, such as the use of the airship for long distances and aeroplanes for shorter services, and the possible use of gas suction plant for propelling locomotives, motor-lorries, and ships, and of benzol and alcohol in the internal-combustion engine.

In view of the national importance of these problems, the creation of a chair of transport at one of the leading universities would be a deserving object for private beneficence. The two Institutions of Civil Engineers and Mechanical Engineers should be more frequently consulted by the Government in regard to road transport, and the National Physical Laboratory had done excellent work. The problem, however, was so vast as to demand continuous research at a special establishment.

The adoption of the annual report of the Executive Committee was proposed by Lord Bledisloe, and seconded by Sir Gilbert Parker, both of whom are vice-presidents of the Guild. A cordial tribute was paid to the valuable services Lord Sydenham had rendered to the Guild during his tenure of office, and both speakers expressed the general appreciation of Lord Montagu's acceptance of office as the new president.

The report, summarised by Lord Bledisloe, dealt with various aspects of the work of the Guild. The second British Scientific Products Exhibition, held in 1919, was honoured by a visit from both King George and Queen Mary, accompanied by Prince Henry and Princess Mary, and demonstrated the growing appreciation by British manufacturers of the value of applied science. During the present year it is hoped to arrange a conference on science and labour in association with the Labour Party. A representative committee is being set up to collect full data on the utilisation of science, not only in the Civil Services, but also in all Government Departments, and the Parliamentary Committee, which has already intervened with good effect in the Forestry Bill, will watch all prospective legislation involving scientific and technical issues. The Education Committee of the Guild is still pressing for a real survey of the existing provision of university and higher technical education in the country, considering that the new Standing Committee on University Grants, acting under the Board of Education, is inadequate as regards composition and reference. The revised specifications of the Technical Optics Committee in regard to microscopes have already been adopted by two British firms.

The adoption of the report having been carried unanimously, the proceedings were terminated by a vote of thanks to the Master and Wardens of the Goldsmiths' Company for permission to hold the meeting in their hall.

Annual Visitation of the Royal Observatory, Greenwich.

DURING the war this annual function was restricted to the official visit of the members of the Board. It has now returned to the conditions that prevailed many years ago, a large and representative gathering of astronomers and their friends being present on Saturday, June 5, to take part in the inspection of the observatory and instruments.

The return of many members of the staff who had been at the Front has naturally brought about a large increase in the number of observations. Those made with the transit circle exceed eight thousand in each element. In addition to the customary observations of sun, moon, planets, and clock-stars, the observing list now includes the stars selected by Backlund and Hough as secondary standards distributed with fair uniformity over the sky. Observations for this catalogue will be completed at the end of 1921.

The error of the moon's place in longitude for 1919, as predicted in the Nautical Almanac, was $-12{\cdot}26''$, showing a notable diminution of nearly $2''$ from the value for the three preceding years. The Astronomer Royal explains that this change is due to the omission in Hansen's tables of several sensible planetary terms. In view of the imperfections of these tables, it is satisfactory to note that Brown's new lunar tables have now been printed and are used in the Nautical Almanac, starting with the year 1923.

Two of the equatorials are now out of use. The 28-in., the mounting of which dates from 1851, requires renewal of the upper pivot; this work has been entrusted to Messrs. T. Cooke and Sons. The driving clock of the astrographic equatorial was sent to Sir H. Grubb for repairs, which are still in progress. The observations of double-stars made with the 28-in. since its erection have been discussed by Mr. Jackson, who has published more than twenty new orbits in the Monthly Notices for March and April last. Fuller details of these and other systems will be printed in the Greenwich annual volumes. There are many systems for which orbits cannot yet be deduced, but where relative motion is shown; hypo-

thetical parallaxes are being deduced in these cases, recent research having proved that such parallaxes are of considerable value for statistical purposes; they are, indeed, as trustworthy as those directly measured when the latter are of the order of 0·02″.

The photographic determination of parallaxes with the 26-in. photographic equatorial has been resumed, and twenty new parallaxes have been determined with an average probable error of 0·008″. It is anticipated that in future forty new parallaxes will be determined annually. The plan adopted for the measurement of the star images on the eclipse plates (that is, the preparation of a key plate with reversed images, which is placed film to film with the plates to be measured) is now being adopted for the parallax plates. Instead of producing the key plate by photography, short lines will be ruled on a glass plate in a north-and-south direction corresponding with the positions of the stars on each set of parallax plates.

A few photometry plates of the Kapteyn selected areas in N. decl. 30° have also been taken.

Two Star Catalogues are in process of being printed, viz. the zone catalogue of stars down to the 9th magnitude in N. decl. 24° to 32°, and the proper-motion catalogue of stars near the North Pole (vol. iii of the Greenwich Astrographic Catalogue).

The proper motions of the stars in both these catalogues have already been discussed in several papers in the Monthly Notices.

The reduction of the solar photographs fell into arrears owing to the impossibility of transmitting plates from India and the Cape to fill the gaps in the Greenwich series. Work is now being pushed on as rapidly as possible, and has been brought up to the middle of 1917. There were considerable solar outbursts in August and March last, both accompanied by magnetic storms, but the general spot activity is now on the decline.

The Astronomer Royal makes allusion in his report to the successful result of the eclipse expeditions of 1919. Transparencies from the plates secured then were on view, and showed both the star images and the splendid prominence 300,000 miles in length which was on the sun's eastern limb.

It is proposed to repeat the investigation of the star-shift at the eclipse of 1922 September 20. According to present plans, Messrs. Jones and Melotte will observe it from Christmas Island, Indian Ocean. They will use the astrographic, mounted equatorially, discarding the cœlostat, which is a source of trouble in work where great refinement is needed. Plans have been mooted for utilising the presence of the instrument in low latitudes to take a series of plates with the view of linking together the northern and southern magnitude scales.

The mean magnetic declination for 1919 is 14° 18·2′, it is diminishing about 9·6′ annually, so that it should reach zero about the end of the century.

As regards the weather of the twelve months ended on April 30 last, it is interesting to note that the period October–November was the coldest for eighty years, while the period December–April was the warmest for eighty years. This accounts for the exceptionally early appearance of the blossoms, which was three weeks in advance of the average.

The daily sunshine register has been supplemented since last January by a small fixed camera pointing to the pole, which records trails of circumpolar stars throughout the night, forming a gauge of the clearness of the sky.

The reception of wireless time-signals from Paris, Nauen, Lyons, and Annapolis now forms part of the daily routine. The times of their reception will be printed in the Greenwich volumes, and will be available for longitude determinations. It has lately been announced that the Lyons signals can be read at Adelaide, so that it is hoped that improved values of the Australian longitudes will shortly be available.

The Astronomer Royal notes the loss that the observatory has sustained in the recent retirement of Messrs. Maunder, Thackeray, and Hollis, and expresses warm appreciation of their long and zealous services.

Applied Statistics.

IT is only twenty-five years since Prof. Karl Pearson gave at University College, London, his first course of lectures on the mathematical theory of statistics, and the opening at University College, London, on Friday, June 4, of the handsome building provided by the generosity of Sir Herbert Bartlett, Bart., for the Department of Applied Statistics, including the Galton Laboratory and the Drapers' Company Biometric Laboratory, marks another stage in the progress of what is more than a new branch of science, for there is scarcely a single field of scientific work in which the fundamental importance of the methods of research which have been developed by Prof. Pearson and his pupils has not been recognised.

The Drapers' Company in 1902 was the first to provide funds to carry on research work in what was then known as the Biometric Laboratory, and is now appropriately called the Drapers' Company Laboratory, and its annual grants have been continued up to the present time; while nine years later Sir Francis Galton bequeathed the residue of his estate to the University of London for the establishment of the Galton professorship of eugenics. Sir Francis expressed the wish, however, that so far as possible the capital of the endowment should be preserved intact, and the University accordingly issued an appeal for the building and equipment of a Francis Galton laboratory. Immediately afterwards Sir Herbert Bartlett offered to provide a building for both the Galton and Biometric Laboratories.

The building was nearly ready for occupation when, on the outbreak of war, not only had it to be given up for use as a military hospital, but also the voluntary services of the staff of the laboratories were offered to and accepted by the Government. In the early days of the war hundreds of diagrams were prepared weekly of the extent of unemployment in all the important towns of Great Britain, and when unemployment ceased to be a serious problem the laboratories were engaged in statistical inquiries into the seasonal use of shipping and rates of exchange and in investigations into aeroplane propeller stresses and ballistics. The computation of sights for various types of machine-guns to be used against low-flying German aeroplanes was carried out by very strenuous and continuous labour in six weeks.

One result of the delay in completing the equipment of the building is that funds which were insufficient in 1914 are now wholly inadequate, and this splendid building can only be partly used. Equally essential is the provision of funds for the salaries of the staff, and it is estimated that to complete and maintain the equipment of the new building and to carry on and develop the work of the laboratories in accordance with the intentions of its founders there is required an additional income of 5000l. a year. The Senate of the University of London has accordingly authorised an appeal for this endowment.

At the opening ceremony, at which Dr. Russell Wells, the Vice-Chancellor of the University of London, presided, Dr. Addison, Minister of Health said that his work in the Ministry of Munitions had

been hindered by the constant struggles to find out what we had and what we wanted, and it was only when they obtained the services of trustworthy statisticians that the Department got into clear order. In the field of public health trustworthy statistics were of equal importance, and he therefore recommended to the public the appeal which had been made for additional funds, and promised to do all he could to help on the work of the laboratories. D. H.

The Imperial College

CLAIM TO UNIVERSITY STATUS

A MEETING in support of the claim of the Imperial College of Science and Technology for power to confer degrees and for university status was held at the Central Hall, Westminster, on Friday, June 4. Lord Morris, who presided, stated that the meeting was not called in hostility to any university or Government Department, or in disparagement of the atmosphere created by the universities. The governing body, the professorial staff, and the students, now numbering 1300, were unanimous in support of the claim of the Imperial College for power to confer degrees in its own subjects or faculties. The students were seriously handicapped by having to go to an external body for a degree, because of the current preference in the industrial and professional worlds for a degree to a diploma. Lord Morris moved a resolution urging the Prime Minister, the Lord President of the Council, and the President of the Board of Education to take the matter into serious consideration. The resolution also declared that any further delay would cause a growing sense of injustice.

Prof. W. W. Watts, who seconded the motion, pointed out that the report of the Departmental Committee, the recommendations of which in 1906 led directly to the establishment of the Imperial College, was based on a vision of a vast technological and Imperial institution, not confined to mere technical instruction, but devoted to the highest education and training in research in both pure science and technology. The Departmental Committee had stated clearly the reasons against incorporating the Imperial College in the University of London, pointing out that if the college was to be able to adapt itself to the ever-changing conditions of industry it must be free from the academic trammels of an education regulated, and rightly regulated, by other aims.

Mr. H. G. Wells, speaking in support of the motion, warned the meeting that in approaching the Lord President of the Council and the President of the Board of Education the delegates would have to combat the suspicion that their proposal involved a system of education and training likely to turn out men and women of narrow culture, mere technical experts without broad views. The curse of education in London had been the grandiose ideas of people who could not distinguish between the Universities of Oxford and Cambridge and the university conditions of London. It was almost impossible to conceive the widely separated college units in London co-operating successfully to form a single efficient university.

Sir Ernest Rutherford, speaking as a representative on the governing body of the Imperial College of the Dominion of New Zealand, said it was not generally recognised how much energy is spent in developing the pure science side of the Imperial College. It was only right and proper that the students, and particularly the oversea students, should have a degree where degree-work had been done, and the degree should be conferred by the teachers, and not by any outside body. Surely we might broaden our ideas of university education in general. We had never before had an institution teaching technology on such a vast scale and to such a high standard as the Imperial College does. There was no precedent for the college, and therefore there could be no precedent against its claim to confer its own degrees. Subsequent speakers included Mr. J. A. Spender, Sir Richard Redmayne, and the Rector of the Imperial College, Sir Alfred Keogh. The resolution, modified slightly in accordance with suggestions made by Mr. H. G. Wells and others, was carried with one dissentient.

The Smoke Nuisance.

THE Manchester City Council is one of the few local authorities which have gone out of their way not only to put the smoke clauses of the old Public Health Act into force, but also to investigate the cost to the community of the smoke nuisance. With true wisdom it has realised that the æsthetic sense of the average man is controlled by his pocket, and that the direct road to reform is to make him understand how much he might save by a clean atmosphere.

We have received from the Air Pollution Advisory Board of the Manchester City Council a pamphlet entitled "The Black Smoke Tax," and although it deals mainly with an elaborate investigation into the relative cost in fuel, soap, and starch in an industrial and a residential centre, there is an introduction which reviews in brief but expressive language other causes of loss and damage which follow in the train of black smoke. The Board says:—"The damage is both æsthetic and economic. The look of things suffers. The value of things suffers. Everybody suffers and, since everybody suffers, it is a long time before anybody protests. If the damage were done suddenly there would be a general outcry, but it is done gradually. Thousands of Manchester people live their lives from start to finish in the midst of black smoke and have come to regard it as a normal condition of life. It is only in modern times that we have realised that the nuisance is preventable and that public economy, public health, and happiness alike call for its prevention."

The investigation has been conducted on the lines adopted in Pittsburgh, U.S.A., which showed an annual loss amounting to 4*l*. a head of the population. A large number of different classes of houses in Manchester (industrial) and Harrogate (residential) were personally visited and the weekly washing bill as nearly as possible ascertained. The net result was an additional expenditure in Manchester of more than 242,000*l*. annually on this item alone. The committee employed on this investigation concludes its report as follows: "As a result of years of patient investigation, coupled with strict rejection of all doubtful evidence, they can state emphatically that it would well repay Manchester to expend a large amount of thought and money on any measures that would help to reduce its enormous yearly smoke tax of at least three-quarters of a million pounds per annum."

The Ministry of Health has now taken the matter in hand and appointed a Smoke Abatement Committee to consider ways and means of abolishing smoke. The report of this committee will no doubt contain recommendations which will give local authorities greater facilities and stronger inducements for dealing with this pest of industrial towns. Coal smoke is opposed to every principle of economy, health, comfort, and cleanliness. It is a national scourge which has been too long tolerated.

J. B. C.

The Molecular Energy in Gases.

BY request of the council of the Royal Society of Edinburgh, an address on "Molecular Energy in Gases" was delivered on May 3 by Principal Sir Alfred Ewing, who began by referring to a series of papers on the foundations of the kinetic theory which were communicated to the society thirty years ago by a great teacher and a great master of the subject, Prof. Tait. Since those days the kinetic theory had received what might be called ocular demonstration through Perrin's investigation of the Brownian movements, which exhibited the buffeting of visible bodies by the blows of the molecules. Much had come to be known regarding the probable structure of the atom. There had been substantial advances in the study of specific heats of gases and of their absorption and emission of heat in the form of infra-red rays. But the difficulty referred to by Tait of reconciling the known facts about specific heat with the theory of the equipartition of energy, as developed by Maxwell and Boltzmann, still remained, and had led to various applications or extensions of Planck's quantum theory, not only to the vibrations of gaseous molecules, but also to their rotations.

Some of these applications of the quantum theory appeared to the lecturer to be highly artificial, and also unnecessary. He proceeded to discuss the correspondence between the observed values of the specific heats and those that might be expected by applying ordinary dynamics to the translations and rotations of the molecules of a gas, and pointed out that the results presented a consistent scheme, which had, however, to be supplemented by taking account of the energy of vibration, especially at high temperatures. Vibratory energy became developed in a manner which was clearly not consistent with the principle of equipartition. It was now known that in all except monatomic gases the specific heat became notably increased at high temperatures, when the vibrations within the molecules began to be an important part of the whole energy. The experimental facts as to this increase were no doubt well expressed by means of Planck's quantum formula, but the type of curve which it gave was one that was found in other departments of physics. It was therefore open to question whether, if the nature of the constraints were understood, the development of vibratory energy in the molecules might not be interpreted in terms of other ideas than those of quanta, and without disturbing the old-fashioned principles of Newtonian dynamics.

University and Educational Intelligence.

BIRMINGHAM.—In common with other universities, that of Birmingham has been overcrowded with students during the past session, and, in order that the necessary arrangements may be made to accommodate the maximum number for the ensuing year, public notice has been given that intending students should make application for entry not later than June 30. Already temporary buildings are being erected to cope with the certain increase in number of second-year students. The problem of adapting the number to be admitted to the available accommodation is undoubtedly difficult, but any method of restriction adopted will be devised with the object of securing admission to the fittest.

CAMBRIDGE.—Announcement is made in the *Times* that the directors of the Commercial Union Assurance Co. have allotted the sum of 165,000*l.* for a building of biochemistry, on a site provided by the University, for the provision of adequate incomes for the professor and his staff and for the endowment of research.

LIVERPOOL.—At a meeting of the Senate of the University held on June 2 the following resolution was passed:—"The Senate records with profound regret the death of Prof. Leonard Doncaster, F.R.S., Derby professor of zoology in the University. But a short time in Liverpool, Prof. Doncaster had taken a prominent place in the University, serving on the University Council as representative of his faculty, and had added to the reputation of the University by his contributions to science, and notably by his text-book upon cytology, published within the last few weeks. As colleague and friend he will be mourned by all members of the University. To Mrs. Doncaster and the members of his family the Senate would offer its most sincere sympathy."

THE Ramsay Memorial Trustees will proceed to the election of not more than three fellows at the end of this month. Applications must be received not later than June 15. Application forms, containing full particulars of the award, can be obtained from the Organising Secretary of the Ramsay Memorial Fund, University College, London. The fellowships are of the value of 300*l.* a year each, and tenable for two years. They are for the advancement of chemical research.

THE annual vacation course in Snowdonia for field-work in geography, geology, botany, map-making, and regional survey methods is being held under the auspices of the Geographical Association on August 7–21, with Llanberis as a centre. Particulars of the arrangements may be obtained by sending a stamped addressed envelope to Mr. H. Valentine Davis, "Noddfa," Wistaston, Crewe. The course is primarily intended for teachers of geography in public and other secondary schools.

LORD ERNLE presided at a meeting held last week at Chelsea House, Cadogan Square, to establish the training of women as skilled scientific cultivators on a national basis. In recognition of the magnificent work achieved, especially during the war, by Swanley Horticultural College in increasing every class of home-grown foods, and also in food preservation, the Ministry of Agriculture proposes to allot a Treasury grant of 10,000*l.* for the re-equipment and further development of this unique training college, provided the public contributes an equal sum. Never has the national need for scientific food production on one hand, and for remunerative and healthy employment for educated women on the other, been greater. Swanley has full capacities for carrying out both these works of national importance once the ravages of five years of war-shortages have been repaired, and the urgently needed new laboratories, lecture-rooms, library, and students' hostels have been erected and equipped. The great demand for women workers in agriculture and horticulture is proved by the fact that the applications from employers for Swanley students rose from 130 in 1914 to 618 in 1918. Prof. Keeble, of Oxford University, pointed out that the future cultivation of England would become more and more intensive, and that this intensive cultivation is now of the greatest national value, significance, and economic justification. Plans for the new science buildings at Swanley are now ready and the site is selected. It only remains for the public to provide the 10,000*l.* required to secure the Treasury grant for this urgent work of national utility. The appeal recently issued is signed by Lord Ernle, late President of the Board of Agriculture and Fisheries; Lord Lambourne,

president of the Royal Horticultural Society; Prof. J. Bretland Farmer; Prof. Keeble; Lady Northcliffe; and Viscountess Falmouth, chairman of the governing body, Swanley College. Donations may be sent to Messrs. Child and Co., 1 Fleet Street, London, E.C.4. Ten thousand pounds is needed at once, and 50,000*l.* for the complete installation of the science department and for the reconstruction of the college and of the intensive training grounds.

Societies and Academies.

LONDON.

Physical Society, May 14.—Sir W. H. Bragg, president, in the chair.—Dr. F. Lloyd **Hopwood**: Experiments on the thermionic properties of hot filaments. The experiments shown were some of those described by Dr. Hopwood in the *Philosophical Magazine* for March, 1915, p. 362, in which the glowing filament of a carbon lamp and glowing filaments of nichrome and platinum in air are made to move under the influence of positively and negatively charged rods brought into or withdrawn from their vicinity, the character of the effects observed being such as to give a qualitative indication of the thermionic emission from the filaments. In addition, he showed a type of tilted electroscope in which the gold-leaf was replaced by a narrow loop of Wollaston wire. When a current is passed through the wire so as to make it glow, it forms an electroscope of different sensitivity for +ve and −ve charges.—G. D. **West**: A modified theory of the Crookes radiometer. The paper gives a short account of a theory of the Crookes radiometer worked out by Sutherland in 1896, but, unfortunately, much neglected. The theory as it stands will not explain many radiometric phenomena, but it is shown that when modifications depending on the modern knowledge of thermal surface conditions are made, such explanations become possible. Radiometer action, especially at the higher gas pressures, would appear to depend essentially on the formation of gas currents near the radiometer vane. These currents are distinct from convection currents, but are closely associated with the phenomena of thermal transpiration.—A. **Campbell**: The magnetic properties of silicon iron (stalloy) in alternating magnetic fields of low value. Measurements are described of the hysteresis losses in silicon iron sheet and wires in very low alternating magnetic fields at low and telephonic frequencies, using an alternating-current method described in a former paper. The equations giving the hysteresis losses as a function of $B_{max.}$ are deduced in the case of the sheet material at low frequencies for ranges of $H_{max.}$ from 0·0002 to 0·02. Comparisons are made between sheet material and wires of different diameters, and curves are given showing the great improvement in the permeability of wires when they are annealed. The behaviour of the material is studied, both by ballistic tests and at telephonic frequencies, as regards the alternating field when direct-current fields of various values are applied at the same time.—T. **Smith**: Tracing rays through an optical system. Equations for tracing rays in an axial plane through an optical system have the normal refraction terms separated from those representing aberrations. By expressing the latter as a fraction with the first-order aberration as the numerator and a correcting factor, which may take various forms, as the denominator, rays may be traced exactly through the system, using a short table of cosines in terms of sines in place of the extensive tables, giving sines in terms of angles generally employed. A considerable saving of time is effected in the calculations, and the estimation, without calculation, of the aberrations of other rays is facilitated.

Geological Society, May 19.—Mr. R. D. Oldham, president, in the chair.—Dr. H. H. **Thomas**, with chemical analyses by E. G. **Radley**: Certain xenolithic Tertiary minor intrusions in the Island of Mull (Argyllshire). The paper deals with a series of minor intrusions, generally tholeiitic but occasionally composite in character, which are well represented in the western peninsula of Mull, lying between Loch Scridain and Loch Buie, and are remarkable for the number and mineralogical peculiarities of the xenoliths that they contain. Xenoliths of a highly siliceous nature (quartzites, sandstones, etc.) are met with, but more commonly the inclusions are of a type rich in alumina (shales and clays). Cognate xenoliths of noritic and gabbroic affinities occur in several of the intrusions, and these, together with the accidental siliceous xenoliths, are briefly described; but the communication deals more particularly with the aluminous inclusions which are crowded together in most of the intrusions, range up to several feet in diameter, and are characterised by well-crystallised minerals such as sapphire, spinel, sillimanite, cordierite, and anorthite. These xenoliths offer the clearest evidence of the modification of a more or less pure aluminous sediment by permeation of magmatic matter, more particularly by the diffusion of lime, ferrous iron, and magnesia. It is held from the evidence afforded by the xenoliths that the metamorphism is of a deep-seated character, and has been effected by a tholeiitic magma on the walls of its basin, which were composed mainly of aluminous sedimentary rocks.

CAMBRIDGE.

Philosophical Society, May 3.—Sir Ernest Rutherford, vice-president, in the chair.—W. J. **Harrison**: Notes on the theory of vibrations. (1) Vibrations of finite amplitude. (2) A theorem due to Routh. Rayleigh determined, in trigonometric form, the approximate effect of small terms varying as the square and cube of the displacement in the equation of simple harmonic motion. In the former of these notes exact Fourier series are determined by the theory of elliptic functions, and tables are computed. The latter note relates to the theorem that an increase of inertia of any part of a vibrating system increases all the periods in such a way that the new periods are separated by the original periods. If the effect of the increased inertia be represented by an addition to the kinetic energy of the square of a linear function of the velocities, it is pointed out that the theorem does not hold unless this linear function involves all the velocities.—W. **Burnside**: On cyclical octosection. The complete solution of the problem of cyclical quartisection was first given by V. A. Le Besgue in *Comptes rendus*, vol. li., 1860, without proof; he forms the quartic equation satisfied by the sum of $\frac{1}{4}(p-1)$ distinct primitive pth roots of unity, p being a prime number of the form $4n+1$. If $p=L^2+4M^2$, where $L\equiv 1 \pmod{4}$, the equation involves p and L, being

$$\{y^2+p[2(-1)^{\frac{p-1}{4}}-1]\}^2=4p\{y-L\}^2,$$

where y is one more than four times the sum in question. The only proof as yet published appears unnecessarily long. The present paper deals with the case when p is a prime of the form $8n+1$; it forms and solves the equation satisfied by the sum of $\frac{1}{8}(p-1)$ distinct primitive p roots of unity, which is capable of eight values, by a method capable of extended application. Expressing p in both the forms a^2+b^2, $a'^2+2b'^2$, this equation involves p, a, and a'.—Dr. G. F. C. **Searle**: (1) A bifilar method of measuring the rigidity of wires. The upper ends A, C of two equal

wires are attached to two torsion heads, and the lower ends B, D to a bar loaded with a considerable mass. When the wires are free from torsion, they are in a vertical plane. The distances $AC=2a_1$, $BD=2a_2$, are nearly equal. If the torsion heads are turned through ϕ from their zeros, the bar will turn through θ in the same direction, until the bifilar couple balances the couple due to the torsion of the wires. Then $\sin\theta=C(\phi-\theta)$, where C is, for practical purposes, independent of ϕ and θ. By observing θ and ϕ, C is found. Then, if r is the mean radius of the wires and M the load supported by them, the rigidity, n, is given by

$$n=\frac{ga_1a_2}{\pi r^4}\cdot MC.$$

A damping device is provided so that steady readings can be obtained in a room subject to vibration. Bends in the wires near the upper ends have the same effect as if the points A, C described small horizontal circles. Errors due to this cause are eliminated by a rough harmonic analysis. (2) An experiment on a piece of common string. When a mass M is suspended by a piece of common string from a fixed support, it begins, when set free, to rotate about the axis of the string. The string, therefore, exerts a couple, G, on the body, and the relation of this couple to M is studied in the experiment. If, starting from rest, the body makes n revolutions in time t, the angular acceleration α, assumed constant, is given by $\frac{1}{2}\alpha t^2=2\pi n$. If K is the moment of inertia of the body, $G=K\alpha$. If the length of the string is of the order of 2 metres, the angular acceleration is approximately uniform for at least the first 10 or 20 revolutions. The load is supplied in the form of a number of equal inertia bars which can be threaded on a light rod carried by the string. Then K is practically proportional to M. It is found that the time for, say, 10 revolutions from rest is nearly constant. Hence G is nearly proportional to M. (3) Experiments with a plane diffraction grating, using convergent light. A lens forms a real image B of a vertical slit S illuminated by sodium light. A plane diffraction grating, with its rulings vertical, is placed between the lens and B, so that the vertical central plane of the beam, which cuts the grating in O, makes an angle θ with the normal to the grating, and $BO=u$. If C is one of the "real" diffracted images of order p, and if CO or v makes an angle ϕ with the normal, then

$$u\sec^2\theta=v\sec^2\phi \quad . \quad . \quad . \quad . \quad (1)$$

If the grating interval is d, the wave-length is given by

$$p\lambda=d(\sin\phi-\sin\theta) \quad . \quad . \quad . \quad . \quad (2)$$

In the experiment the relation (1) is tested, and the wave-length is found by (2). The images are received on a glass scale moving along an optical bench, the length of the scale being horizontal and perpendicular to the bench.—Major P. A. **MacMahon**: Congruences with respect to composite moduli. This paper deals with the primitive roots of the binomial congruence the exponent of which is any divisor of the totient of a composite modulus. Numbers being divided into categories according to the number of their different prime divisors, tables of primitive roots are given for the cases of the second and third categories.—A. **Kienast**: Equivalence of different mean values. This is a continuation of a former paper by the author, and deals with the equivalence of conditions for the existence of the limit of the mean sum of a continually increasing number of terms.—Prof. H. F. **Baker**: Construction of the ninth intersection of two cubic curves passing through eight given coplanar points. Let A, B, C, M, N and P, Q, R be the given points; take T external to their plane; let TP, TQ, TR meet a quadric containing A, B, C and the lines TM, TN, in further points P′, Q′, R′; let the twisted cubic curve through T, A, P′, Q′, R′ which has BC for chord meet the quadric again in O′; then TO passes through the required ninth point.—W. E. H. **Berwick**: Quintic transformations and singular invariants. This paper deals with the arithmetical solution of a certain sextic equation arising in the theory of modular functions, the coefficients of which are functions of a certain algebraical number. The arithmetical character of the number of fields which arise is determined in detail.

MANCHESTER.

Literary and Philosophical Society, May 4.—Mr. William Thomson, vice-president, in the chair.—Major T. **Cherry**: The origin of agriculture. The annual flood-cycle of the Nile provided perfect conditions for the growth of cereals. Since none other of the great rivers on the banks of which civilisation first appeared afforded such natural possibilities for the growth of cereals, it was claimed that man must have learned in Egypt irrigation and the cultivation of cereals. The author, in discussing the origins of wheat and barley, claimed that the originals of our cultivated barley probably evolved in the Nile Valley, and those of our wheat on one of the islands of the Ægean Archipelago.

Literary and Philosophical Society (Chemical Section), April 30.—Mr. J. H. Lester, chairman, in the chair.—Dr. J. A. R. **Henderson**: Alchemy and chemistry among the Chinese. The early objects of the alchemists were discussed, and their discoveries in metallurgy, mineralogy, and botany detailed. The latter included the manufacture of pigments, lacquers, porcelain, paper, and the early discovery of the explosive properties of gunpowder. The exploitation of vast coal deposits and of iron and other metallic ores, and the production of oils and medicinal substances, are taking place.

May 14.—Mr. J. H. Lester, chairman, in the chair.—Prof. F. L. **Pyman**: The relation between chemical constitution and physiological action.

DUBLIN.

Royal Irish Academy, May 10.—The Most Rev. the Right Hon. J. H. Bernard, president, in the chair.—J. N. **Halbert**: Acarina of the Intertidal Zone. The various forms, several of which are new to science, were studied in their relation to the well-known zones, or belts, of the orange lichen, Pelvelia, and Fucus usually present, where there is sufficient foothold for them, on the sea-shore. Excluding the families Halacaridæ and Hydrachnidæ, the species are distributed in the four terrestrial families as follows: Gamasidæ 28, Oribatidæ 17, Tyroglyphidæ 2, and Trombidiidæ 18.—Miss Jane **Stephens**: The freshwater sponges of Ireland. The fresh-water sponges of Ireland number only five species. Their habitat, mode of growth, and distribution are discussed. Among the points of interest are the following: It has been found that the sponges do not occur in mountain streams, unless there is a lake, however small, in the course of the stream, and that, on the other hand, they occur most luxuriantly in a stream just below its exit from a lake. One species avoids the limestone areas. The variations of the commoner species are traced at some length. The paper is illustrated by numerous drawings of spicules and by maps showing the distribution of the species.—T. A. **Stephenson**: The genus Corallimorphus. *Corallimorphus* is a genus of deep-sea Actiniaria, first described by Moseley in 1870, and later by Hertwig in 1882 and 1888. There are two specimens of *C. rigidus* in the collection of anemones made by the Fisheries Branch

of the Department of Agriculture and Technical Instruction for Ireland from 1899 to 1913. These specimens are described externally and anatomically in the paper, and compared with the eight other specimens described by Moseley and Hertwig. The possibility of all these specimens belonging to one species is suggested and discussed, with the conclusion that it is quite likely that the genus contains one variable species only. On the other hand, further material is required for a final decision, and if the three species, *C. rigidus, profundus*, and *abtectus*, should prove valid, the Irish specimens would probably require a fourth species. It is further pointed out that the thick and rigid body of the anemones in question seems to be correlated with deep-sea life, and that although the genus has sometimes been regarded as a primitive one, it has a number of characteristics which it would seem can be considered only as specialisations or advanced features.

PARIS.

Academy of Sciences, May 25.—M. Henri Deslandres in the chair.—E. **Goursat**: Some transformations of partial differential equations of the second order.—G. **Bigourdan**: The instruments and work of the Sainte-Geneviève Observatory. Historical account of the work of Pingré and of Lechevalier done between 1755 and 1836.—J. **Bossert**: Catalogue of the proper motion of 5671 stars, annotated and published by L. Schulhof.—J. **Baillaud**: The method of the scale of tints in photographic photometry.—C. **Guichard**: Congruences belonging to a linear complex such that the lines of curvature correspond on the two focal surfaces.—G. **Julia**: Families of functions of several variables.—M. **Janet**: Systems of partial differential equations and systems of algebraic forms.—G. **Sagnac**: The real relativity of the energy of the elements of radiation and the motion of waves in the æther.—F. **Vlès**: Ultra-violet spectrophotometry of the nitrophenols. Seventeen nitro-derivatives were examined and the spectra found to be, in general, constituted of three elements: a constant band, due to the NO_2 group; a band related to the presence of the benzene ring; and a third band the origin of which is doubtful.—M. **de Broglie**: The fine structure of X-ray spectra. Details of a doublet given by rhodium, and comparison with the K spectrum of tungsten.—J. L. **Pech**: Phenomena of antagonism between various radiations (ultra-violet, visible spectrum, and infrared).—L. **Thielemans**: Regulation of cables for the transport of electrical energy to long distances.—P. **Bunet**: The transport of energy to great distances. Remarks on a recent communication by M. Brylinski on the same subject.—M. **Toporescu**: The lime and magnesia carried down by precipitates of ferric oxide. Varying weights of ferric oxide were precipitated in presence of constant quantities of calcium and magnesium salts, and the proportions of lime and magnesia carried down were determined. A second precipitation of the ferric oxide is sufficient to remove calcium salts, but this is not the case with magnesia.—L. **Guillet** and M. **Gasnier**: The plating with nickel of aluminium and its alloys. The aluminium or alloy is cleaned and roughened by sand-blasting, and then takes a satisfactory deposit of nickel. The influence of the size of the sand grains and the time elapsed between the sand-blasting and the deposit have been examined, and results are given.—A. C. **Vournazos**: A new series of complex combinations: the antimony oxyiodides. The mercury compound may be taken as a type of these substances; it has the composition $Hg(SbIO_2)_2$.—R. **Cornubert**: The constitution of some dialkylcyclohexanones. A study of the ketones obtained by treating cyclohexanone with sodium and then with alkyl halides.—C. **Dufraisse**: The stereo-isomeric forms of benzoylphenylacetylene di-iodide. The conditions under which either of the two isomers can be isolated are given.—A. **Mailhe**: The catalytic hydrogenation of the ketazines.—L. **Moret**: The tectonic of the eastern bank of Lake Annecy.—A. **Brives**: Some results of a new journey in Morocco. A completion of geological work commenced in 1919.—P. **Bonnet**: The Permo-Triassic limit in the Himalayan-Armenian geosynclinal.—L. **Dunoyer** and G. **Reboul**: The prediction of the weather.—G. **Truffaut** and H. **Bezssonoff**: The influence of partial sterilisation on the composition of the microbial flora of the soil.—R. **Souèges**: The embryogeny of the Solanaceæ. Development of the embryo in Hyoscyamus and Atropa.—P. **Bertrand**: The constitution of the vascular system in ferns, in Pteridosperms, and in all ancient Phanerogams.—L. **Blaringhem**: The stability and fertility of the hybrid *Geum urbanum* × *G. rivale*. From the morphological point of view the descent of this hybrid is uniform and regularly fertile. Its mixed characters are sufficiently distinct from those of its parents to give a precise diagnosis, and as it propagates without variation in the wild state it can be described as a good systematic species.—J. **Feytaud**: The kings and queens of *Leucotermes lucifugus*.—A. **Mayer**, A. **Guieysse**, and E. **Fauré-Fremiet**: Pulmonary lesions determined by suffocating gases.—A. **Trillat** and M. **Mallein**: The projection of micro-organisms into the air. The influence of humidity.

Diary of Societies.

THURSDAY, JUNE 10.

INSTITUTION OF MINING ENGINEERS (at Geological Society), from 11 a.m. to 5.—(General Meeting.)—Prof. H. Louis: Compensation for Subsidences.—W. Maurice: The Fleissner Singing-flame Lamp.—W. Maurice: The Wolf-Pokorny and Wiede Acetylene Safety-lamps.—G. Oldham: The "Oldham" Cap Type Miner's Electric Safety-lamp.—Discussion on First Report of the Committee on "The Control of Atmospheric Conditions in Hot and Deep Mines."—D. S. Newey: A New Method of Working Thick Seams of Coal at Baggeridge Colliery.—T. G. Bocking: Protractors.—T. G. Bocking: Magnetic Meridian Observations; A Method of Utilising the Kew Observatory Records.

ROYAL SOCIETY, at 4.30.—Prof. A. V. Hill and W. Hartree: The Thermo-Elastic Properties of Muscle.—Sir James Dobbie and J. J. Fox: The Absorption of Light by Elements in the State of Vapour: (1) Selenium and

Tellurium; (2) Mercury, Cadmium, Zinc, Phosphorus, Arsenic, Antimony.—Dr. A. E. H. Tutton: Monoclinic Double Selenates of the Copper Group.—H. G. Cannon: Production and Transmission of an Environmental Effect in *Simocephalus vetulus*.—E. C. Grey: The Enzymes of *B. coli communis* which are Concerned in the Decomposition of Glucose and Manitol. Part IV. The Fermentation of Glucose in the Presence of Formic Acid.—L. T. Hogben: Studies on Synapsis. II. Parallel Conjugation and the Prophase Complex in Periplaneta, with Special Reference to the Premeiotic Telophase.

LONDON MATHEMATICAL SOCIETY, at 5.—G. I. Taylor: (1) Tidal Oscillations in Gulfs and Rectangular Basins. (2) Diffusion by Continuous Movements.—H. B. C. Darling: Proofs of certain Identities and Congruences enunciated by Mr. S. Ramanujan.—M. J. M. Hill: The irreducibility of the Solution f an Algebraic Differential Equation.—F. B. Pidduck: Functions of Limiting Matrices.—W. P. Milne: The Relation between Apolarity and a certain Porism of the Cubic Curve.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. F. Hurst: The Psychology of the Special Senses and their Hysterical Disorders (Croonian Lecture).

CONCRETE INSTITUTE, at 7.30.—E. L. Joseph: Ventilation and Air-Purification as applied to Modern Concrete Buildings.

OPTICAL SOCIETY, at 7.30.—Miss A. B. Dale: Accuracy of Setting.—Dr. J. S. Anderson: A New Method of Immersion Refractometry.

INSTITUTE OF METALS (at Institution of Mechanical Engineers), at 8.—Prof. C. A. F. Benedicks: Recent Progress in Thermo-Electricity (Annual May Lecture).

SOCIETY OF ANTIQUARIES, at 8.30.

FRIDAY, JUNE 11.

INSTITUTION OF MINING ENGINEERS (at Geological Society), from 11 a.m. to 5.

ROYAL ASTRONOMICAL SOCIETY, at 5.—E. E. Barnard: Nova Persei No. 2 (Anderson).—A. S. Eddington: Radiation-pressure in Solar Phenomena.—R. A. Sampson: Geophysical Discussions, 1920 May 7: Determination of Longitude by Wireless Telegraphy.—Gén. Ferrié: Note sur les procédés actuels d'emploi de la télégraphie sans fil dans la détermination des Longitudes.—R. A. Fisher: A Mathematical Examination of the Methods of Determining the Accuracy of an Observation by the Mean Error and by the Square Mean Error.—H. S. Plaskett: The Intensity Distribution in the Continuous Spectrum and the Intensity of the Hydrogen Lines in γ Cassiopeiæ.—J. Lunt: The Spectra of Nova Aquilæ No. 3. Third Paper.

PHYSICAL SOCIETY OF LONDON, at 5.—Dr. T. Barratt and A. J. Scott: Radiation and Convection from Heated Surfaces.—J. S. G. Thomas: An Electrical Hot-Wire Inclinometer.—L. F. Richardson: Convective Cooling and the Theory of Dimensions.—J. W. T. Walsh: The Radiation from a Perfectly Diffusing Circular Disc.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

MONDAY, JUNE 14.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—Very Rev. Dean Inge: Freedom and Discipline (Annual Address).

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Central House, Finsbury Square), at 5.—(Annual Meeting.)

SOCIETY OF ENGINEERS (at Geological Society), Special Summer Meeting, at 5.30.—E. Cressy: Great Engineering Adventures.

FARADAY SOCIETY (at Chemical Society), at 8.—Dr. A. Fleck and T. Wallace: Conduction of Electricity through Fused Sodium Hydrate.—Dr. H. F. Haworth: The Measurement of Electrolytic Resistance using Alternating Currents.—J. L. Haughton: The Measurement of Electrical Conductivity in Metals and Alloys at High Temperatures.—N. V. S. Knibbs and H. Palfreeman: The Theory of Electrochemical Chlorate and Perchlorate Formation.—J. B. Firth: The Sorption of Iodine by Carbon.—F. H. Jeffery: The Electrolysis of Solutions of Sodium Nitrate using a Copper Anode.—Dr. A. M. Williams: The Pressure Variation of the Equilibrium Constant in Dilute Solution.—Miss Nina Hosali: Description of Models illustrating Crystalline Form and Symmetry.

TUESDAY, JUNE 15.

ROYAL HORTICULTURAL SOCIETY, at 3.—Dr. A. B. Rendle: Plants of Interest in the Day's Exhibition.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. F. Hurst: The Psychology of the Special Senses and their Hysterical Disorders (Croonian Lecture).

ROYAL STATISTICAL SOCIETY, at 5.15.—G. F. Shirras: Some Effects of the War on Gold and Silver.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—W. A. Richardson: The Fibrous Gypsum of Nottinghamshire.—F. P. Mennell: Rare Zinc-Copper Minerals from the Rhodesian Broken Hill Mine, Northern Rhodesia.—Prof. R. Ohashi: The Plumbiferous Barytes from Shibukuro, Prefecture of Akita, Japan.—W. A. Richardson: A New Model Rotating Stage Petrological Microscope.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. P. Chalmers Mitchell: Report on the Additions to the Society's Menagerie during the Month of May, 1920.—Prof. J. E. Duerden: Exhibition of, and Remark on, Ostrich Eggs.—Miss Joan B. Procter: (1) A Collection of Tailless Batrachians from East Africa made by Mr. A. Loveridge in the Years 1914–19. (2) The Type-specimen of *Rana holsti*, Boulenger.—R. I. Pocock: The External and Cranial Characters of the European Badger (Meles) and the American Badger (Taxidea).—Dr. R. J. Tillyard: The Life-history of the Dragon-fly.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—Prof. F. G. Parsons: Distribution of Hair and Eye Colour in the British Isles.

WEDNESDAY, JUNE 16.

ROYAL METEOROLOGICAL SOCIETY (at the Royal Astronomical Society), at 5.—W. H. Dines: The Ether Differential Radiometer.—Prof. S. Chapman and E. A. Milne: The Composition, Ionisation, and Viscosity of the Atmosphere at Great Heights.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Mechanical Engineers), at 6.—Discussion on paper read by Sir Dugald Clerk before the Royal Society of Arts, entitled Distribution of Heat, Light, and Motive Power by Gas and Electricity.—Sir Dugald Clerk, Prof. A. Smithells, and Prof. J. W. Cobb: The Report on the Coal Gas and Electrical Supply Industries of the United Kingdom to the President of the Institution of Gas Engineers.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Sir Horace Darwin and W. G. Collins: A Universal Microtome.—L. Hogben: The Problem of Synapsis.

THURSDAY, JUNE 17.

ROYAL SOCIETY, at 4.30.—Prof. W. Bateson: Genetic Segregation (Croonian Lecture).

LINNEAN SOCIETY, at 5.—Celebration of the Centenary of Sir Joseph Banks, Bart. (1743–1820).—Dr. B. Daydon Jackson: Banks as a Traveller.—Dr. A. B. Rendle: Banks as a Patron of Science.—J. Britten: Banks as a Botanist.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. A. F. Hurst: The Psychology of the Special Senses and their Hysterical Disorders (Croonian Lecture).

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Prof J. C. McLennan: Helium.

FRIDAY, JUNE 18.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir Valentine Chirol: The Enduring Power of Hinduism (Sir George Birdwood Memorial Lecture).

GEOPHYSICAL COMMITTEE (at Royal Astronomical Society), at 5.—Commander H. D. Warburg, Prof. H. Lamb, Dr. J. Proudman, Prof. A. F. Dodson, Major A. J. Wolff, and H. L. P. Jolly: Discussion on Tides.

SATURDAY, JUNE 19.

BRITISH PSYCHOLOGICAL SOCIETY (at University College, Gower Street), at 3.30.—Dr. J. Drever: The Emotional Phases of Affective Experience.

PHYSIOLOGICAL SOCIETY (at Physiological Laboratory, University of London, South Kensington), at 4.30.—G. Aured and C. Lovatt Evans: The Mode of Action of Vaso-dilator Nerves.—C. Lovatt Evans: The Lactic Acid Content of Plain Muscle.

University Stipends and Pensions.

NO one disputes that "there is no organised intellectual unit higher or more comprehensive than a University," and few, on reflection, would differ from Sir John Seeley in affirming that the education in England is what the Universities choose to make it. Not only are the Universities and institutions of University rank the highest product of our educational system, but they also have the power of influencing the trend of thought and ideals in education to an incalculable degree. To a large extent, therefore, the advance to a higher plane of civilisation is dependent upon their free and untrammelled development. In pursuit of truth, whether in philosophy, or science, or technology, independent of material considerations, they are pioneers of research, blazing the trail for industry, commerce, and those human efforts which add to the sum of life's happiness. Anything which acts as an impediment or hindrance to this development cannot be viewed simply as an injury to the institutions themselves; it is an injury to the community, to the nation, and to civilisation. If this be true, one or two facts of capital importance require to be considered in the light of a few principles. For the moment, however, let us examine the broad relations of the State to the University.

The State can no more dispense with the co-operation of the Universities than the Universities with the co-operation and assistance of the State. Their interests are mutual and their services reciprocal. The influence of the University ramifies through the whole of the administration of the country, its great Departments of State and its two legislative Houses, its local governing bodies and its courts of justice. Obviously the State cannot afford to see the Universities or the University colleges wilt under economic pressure. Now this is precisely what will happen if it does not take a clearer view of its responsibilities and their logical implications. The University grant, demonstrably insufficient in pre-war times, is absurdly inadequate now. Not merely have money values changed to an extraordinary extent, but the demands upon the Universities in regard to accommodation, equipment, and facilities for research have increased to an almost equal degree. If to these be added the necessary adjustments in salaries of the staffs, the inadequacy is still more apparent.

The State will have to recognise these facts and, if for no other reason than that of enlightened self-interest, to assume heavier financial responsibilities. As matters stand at present, those borne by the State are altogether disproportionate to the services rendered by the Universities to the nation. In consequence, the statement is as true to-day as it was when made ten years ago that our newer Universities are "a composite figure in which progress and poverty are the prevailing hues." But such increased financial responsibility should not absolve the State from preserving in its traditional integrity that freedom which is the life-blood of an institution coeval in origin with Parliament itself. It is platitudinous to say that no one wishes to see the Universities, new or old, in any sort of intellectual subjection. Unfortunately, however, intellectual subjection is too often the outcome of material subjection. A wise State will show its wisdom in preserving in all its integrity that from which it derives, indirectly though it be, its vital energy, and through which it renews its spiritual life from generation to generation.

On broad and general grounds we have argued that the State has responsibilities to the institutions of higher learning of which it cannot divest itself, and that these responsibilities are such as can be fulfilled only by much more generous financial support than is given at present. It is necessary, therefore, to indicate how seriously these institutions are affected by the lack of this support. The question of stipends and pensions alone will be considered. Too often a university is conceived in terms of stone and mortar; essentially, however, it is a corporation, a society of human beings, a body of teachers and students. To say that an efficient and highly qualified staff is fundamental is simply to express a truism. Such a staff is the product of many years of patient and unremitting study. If by any mischance or lack of vision the flow of able and gifted students to this higher teaching is checked, the loss will be irreparable. That such a result

is not a remote possibility is becoming sufficiently obvious to those who are watching the present trend of University affairs. A teacher does not enter on his career in the hope of amassing riches. With such an ambition the teaching profession is among the last to which he would resort. Debarred from the financial prizes possible to a business career, he has the right to expect emoluments which will enable him to live decently and to move in a social circle to which his education and training entitle him. This is especially true of the University teacher.

Now, as a matter of fact, the stipends of University teachers in this country at the present time, particularly in the non-professorial staff, do not conform to this standard, but fall miserably short of it. A large proportion of assistant lecturers and demonstrators, full-time teachers, receive no more, and some much less, than 250*l.* a year—a salary or wage which, under present conditions, would be accepted by no self-respecting mason or miner. The grade of lecturer, comprising as it does a great number of men and women who can never hope to attain professorial rank, however well qualified for it by ability and experience, fares little better. The average salary of this class ranks somewhere near 400*l.* a year, and one may take it that the pre-war value of this sum is approximately equal to 200*l.* a year. If the average rate of remuneration of such posts remains at these figures, it requires no gift of prophecy to predict that the flow of talent to the teaching staffs of the Universities and University colleges will inevitably be checked.

The question of the remuneration of the non-professorial element is most important. The numbers are great, the aggregate hardships intolerable. But the stipends of professors as a whole also show little relation to the emoluments in corresponding positions outside the University. A large number of professors receive less than 800*l.* a year, and considerably more than 80 per cent. less than the professorial salary indicated by the Association of University Teachers as a minimum—viz. 1100*l.* a year. Obviously, again, the gift of prophecy need not be conjured up to predict the result. Already the professorial ranks have been, and are being, depleted by the superior inducements offered in industrial, scientific, and commercial business organisations. It is futile to argue that public benefactions should make good these pressing needs. One cannot dragoon public benefactions. It is too much to expect the local authorities and the students to make good the deficiencies. Generally speaking, both contribute reasonable proportions. The matter is a State affair, and the State must implement to the full its responsibilities.

The present position regarding superannuation is very unsatisfactory. As a general principle, it may be laid down that anything which restricts the field from which the University recruits its staff is inimical to University interests, and hence, in the long run, to education in general. Now the effect of the School Teachers (Superannuation) Act, 1918, is to restrict this field. Any school teacher eligible for its benefits cannot accept an appointment in a University without sacrificing pension rights, in whole or in part. Thus it interposes a barrier—in some cases insurmountable—between the University on one hand, and the technical colleges, the training colleges outside the University, and the schools on the other. The free transfer of teachers to the University is hampered. Already cases are on record of candidates refusing University appointments on finding that acceptance would entail a loss of pension benefits accruing from the Act. It would be most unfortunate if service in schools—a most useful experience for a future University teacher—is to be a bar to later service in the University.

Another effect of the Act is to draw an invidious distinction between existing University teachers and other teachers. Ninety-five per cent. of the whole teaching profession are now eligible for pension benefits incomparably superior to any previous teachers' scheme; while 5 per cent., the University teachers, are excluded, and excluded without any compensation. The position is illogical, unjustifiable, and detrimental to education. One or two illustrations will make this clear. In the University of London some schools of the University come within the provisions of the Act; the rest do not. Thus transfers from one school to another within the same University are made difficult or even impossible. The principal of the Government School of Art attached to a certain University college is said to be the only principal of such a school who is not qualified under the Act—this solely because his school forms part of the University college. In other districts neighbouring institutions engaged in the training of teachers are distinguished from one another in the matter of superannuation, because one forms a department of a University and the other does not. This is in spite of the fact that the two institutions are doing the same kind of work, for the same purpose, under the same authority (the

Board of Education), and that their students do their teaching practice in the same kind of schools under the same local education authority. These facts would be highly diverting were their consequences not so serious.

This anomalous state of affairs has provoked much criticism in University circles. What complicates matters is the fact that there exists a contributory pension scheme in the Universities—the federated superannuation scheme—which is thought by some to be superior to the Teachers Act in certain respects, such as in cases of death during service and of retirement before the age of sixty, and in the form of benefit on retiral. As against these the Teachers Act is non-contributory, it is retrospective, and its benefits are calculated upon the average salary in the last five years of service. The whole question has been considered by a conference of representatives from the Universities of England and Wales, at which it was unanimously resolved to lay the case before the Chancellor of the Exchequer in terms of the following resolutions:—

"(1) That this Conference is of opinion that the interests of English and Welsh education as a whole demand the institution of a scheme of superannuation for University teachers and administrative officials conferring benefits not inferior to those granted under the School Teachers (Superannuation) Act, 1918, and of a like retrospective character; (2) that such a scheme should make due provision (*a*) for the superannuation of persons who enter the service of a University or University college so late in life as to be unable to acquire the service qualification necessary under the School Teachers Act; (*b*) for meeting the case of persons who retire before the normal age of retirement; and (*c*) for meeting the case of persons who die on service. (3) That any scheme of superannuation for University teachers and administrative officials should be of such a nature as to allow (without loss in respect of superannuation) the transfer of a person employed at a University or University college to another approved educational or scientific institution in Great Britain or *vice versa*."

The term "institution," of course, includes schools. These resolutions have been accepted by the Association of University Teachers. Whatever be the result, it is a great step forward to have secured unanimity on essentials. The resolutions have clearly demonstrated the present absolute inadequacy of the federated superannuation system and the difficulty of patching up its deficiencies as regards retrospective benefits, interchangeability of teachers, and the amount of retiral allowances or annuities.

Aerography.

The Principles of Aërography. By Prof A. McAdie. Pp. xii+318. (London: G. G. Harrap and Co., Ltd., 1917.) Price 21s. net.

FROM time to time it has been a subject of remark by the learned that a book on meteorology has to be a collection of essays, because the available material does not lend itself to exposition in a connected treatise. The substitution of the new name aerography for the older meteorology has not changed the leopard's spots. Indeed, Prof. McAdie has made the peculiarities of the subject more remarkable by presenting a work which is partly a collection of meteorological essays, and partly the note-book of a physicist interested in the study of the atmosphere.

Out of eighteen chapters, the first four are a recitation of the physical meteorologist's "credo," which includes absolute units as a theme with variations, preceded by a brief history. There follow nine chapters, which are partly note-book and partly essay; then the essay gradually extends its claim in chapters on atmospheric electricity, precipitation, floods, and notable storms, until it fully asserts itself in a chapter on frosts. Finally, a couple of pages of solar influences lead us to an appendix of conversion-tables and an excellent index.

It is the characteristic of the note-book which will appeal most to the reader. We find a summary of references to the results of modern aerological research which are frequently wanted and not elsewhere at hand. Very useful information about investigations with kites, pilot balloons, and sounding balloons is put in an attractive form. It includes, on p. 19, a table of extreme elevations reached by various means, and much other information of like character. The whole is well illustrated by photographs, maps, and diagrams. It is rather discursive. It begins with the troposphere and stratosphere; winds follow the "major circulation" and the "minor circulation." Ocean currents get a "look in" with the major circulation.

The "credo" is interesting; it shows how careful one has to be in choosing words to express one's meaning. The student has to think when he reads: "The gas constant for the air is not constant. It varies . . . owing to the non-adiabatic character of the atmosphere." "It should be remembered that a gram of ice is by weight a little more than a cubic centimetre, and if pure ice is used only 73 calories are needed" (for liquefaction). Very little unorthodoxy is

allowed to escape through the meshes of the author's critical net, but he is apparently not concerned with the prevalent yet distracting use of the word "gradient" to mean rate of loss per unit length either in the vertical or horizontal direction when speaking of temperature. In this country we are becoming accustomed to confine the word "gradient" to what is commonly understood when it is used with pressure, and to use "lapse" for vertical changes, which are normally losses, with increasing height.

As readers of NATURE already know, it is part of Prof. McAdie's "credo" that pressure should be expressed in "kilobars," which are now commonly known as "millibars," and that temperature should be expressed in new absolute units of which 1000 go to 273 degrees of the Centigrade scale. In the reviewer's experience of units the whole world is divided into three very unequal parts. By far the largest part is made up of persons who think that absolute units for practical concerns are obviously impossible because the man in the street does not "understand" them at all; the next largest of those who think that absolute units in practice are quite unnecessary because any competent man of science fully understands them and can make the transition whenever he requires them; and the third is a small body of persons who are devoted to their use because the scientific future of meteorology lies that way. To change once more the already changed in order to remove an apparent historical inconsistency conveys no promise of ranging the well-informed minority on the side of progressive action, but would hand us over helpless to the judgment of the great majority who do not "understand," and who are obsessed with the idea that scientific results are naught if they cannot be used without thinking.

Among the excellent illustrations of the book are some photographs of cloud-forms. Its author is very insistent that Luke Howard's classification of cloud-forms on the basis of appearance, as extended by the international conferences, is wrong in principle. He thinks they should be classified according to origin. Unfortunately, the appearance is all that an observer can record, and to ask the ordinary observer to differentiate between similar appearances according to some general instruction as to origin would add materially to the difficulties of the student. What is most wanted is some effective means for the individual observer to ascertain the height of the cloud which he sees. Some simple form of range-finder for clouds suitable for the chief observatories ought not to be beyond the limit of possibility.

The book comes from Blue Hill Observatory, now a part of Harvard University, and contains much incidental information as to the great services which that establishment has rendered to meteorology. Its many friends and admirers in this country will welcome the attempt of its present chief to set out the leading principles of aerography which the observatory has done so much to elucidate.

Paper-making and its Machinery.

Paper-making and its Machinery: Including Chapters on the Tub-sizing of Paper, the Coating and Finishing of Art Paper, and the Coating of Photographic Paper. By T. W. Chalmers. (The *Engineer* Series.) Pp. xi + 178 + vi plates. (London: Constable and Co., Ltd., 1920.) Price 26s. net.

THE author in his preface has rightly stated that the chemist interested in paper-making finds ample technical literature at his disposal, whereas the engineer is not provided with any books dealing with the peculiar mechanical problems of his industry. Since the publication of Hofmann's treatise on "The Manufacture of Paper" in 1873 no serious attempt has been made to supply the paper-maker with an intelligent and comprehensive text-book devoted to a study of the economic and efficient control of the machinery peculiar to the manufacture of paper.

Mr. Chalmers's effort in this direction, admirable as it is, regarded in its proper aspect as a pioneer to some such technical treatise, falls far short of our expectations in this direction. It is doubtful whether a really practical and useful text-book on the engineering problems of the paper industry will ever be written. The utility of the book we have in mind will depend on a free and frank *exposé*, by an engineer thoroughly acquainted with the art and practice of paper-making, of conditions, methods, economics, power costs, capacities, output, means for overcoming difficulties, and the hundred "wrinkles" born of long apprenticeship. The description of paper-machines and subsidiary appliances, essential as it certainly is, constitutes only one part, and that the minor part, of an ideal manual.

The causes which have contributed to this lack of information may be traced to the somewhat natural reluctance on the part of a practical engineer to "give away" his knowledge. Every engineer fondly believes he has a monopoly of this kind, and the difficulty of shaking him from such an idea may fully account for the absence of a text-book which would be gladly welcomed by the trade. We may therefore reasonably hope that the present work will inspire some paper-maker to write a supplement.

Mr. Chalmers has done good service in showing that the processes involved are so many as to justify the issue of a book giving detailed descriptions of the special machinery.

After a brief introductory chapter dealing with sundry historical facts the author proceeds to classify the machinery and apparatus under the several processes of manufacture, beginning with rag-choppers and dusters, as required for cleaning material preparatory to chemical treatment. The well-known types of cutters and dusters are clearly illustrated.

The section devoted to the boiling of fibrous material is incomplete owing to the omission of multiple-effect evaporators, the rotary incinerator furnace, causticising pans, and the plant necessary for the recovery and causticising of spent liquors. This is to be regretted.

The processes for washing, breaking, and bleaching the boiled materials are next described, being accompanied by drawings of machinery in common use. Masson and Scott's bleaching-tower system is shown as dependent for its efficiency on the continual circulation of bleached stock. Experience has proved that intermittent circulation gives good results with economy in power. Plant used for pulping is well represented by the Kollergang and various kneading machines.

The important and difficult subject of beating is fairly handled, the temptation to describe "freak" beating engines being avoided. The merits of beaters with separate circulating devices are discussed, and the special functions of refiners clearly described. The value of this section of the book would have been greatly enhanced by the inclusion of precise details as to power consumption, capacity, output, and costs of maintenance. The author appears to have confined his attention to the description and illustrations of the machinery.

Chaps. vii. to xi. are devoted to the production of an endless sheet of paper, and give an excellent account of the Fourdrinier machine used for this purpose. The illustrations are mainly produced from the machine in operation at the *Daily Telegraph* paper-mills, Dartford.

The wear-and-tear of the machine wire is amply shown by the statement that the load on a 100-in. machine wire may be 1½ tons, due to the vacuum at the suction-boxes. No reference is made to the much-advertised suction-roll which came into prominence some years ago.

The importance of a stuff-catcher, or economiser, for saving the fine fibres and loading in the backwater is referred to, and Füllner's save-all stands as the typical machine for the purpose. This appliance is now almost entirely superseded by the vat-mould type of save-all with large, hollow cylinder and endless felt.

The many designs of pulp-strainers are fully illustrated, from the original flat type of early days to the circular, oscillating forms of modern times. The finishing processes of paper-making are illustrated by tub-sizing machines, calenders, and cutters.

Chap. xiv. is devoted to a description of wood-pulp and its manufacture, necessarily brief because very little wood-pulp is made in this country. Only one or two mills are seriously occupied with its manufacture.

The two most interesting chapters in the book are those dealing with "The Coating of Art Paper" and "The Coating of Photographic Paper." The author is probably correct, so far as our memory serves us, in saying that the information given in this connection is in many respects quite new, and much fuller than any previously published.

A full description of a plant for coating art paper, manufactured by Messrs. Mather and Platt, Ltd., is illustrated with excellent drawings and diagrams. It is, of course, well known to our readers that the paper when coated is formed up into long loops, or festoons, which are carried along on endless chains, being gradually dried by warm air. A long room is used for the purpose. In some cases the trackway has to be made longer by bending, so that the festoons can be carried to and fro in a short room. This is effected by the use of "bends" in the trackway, and a complete lay-out of an installation of this kind made by Messrs. Masson, Scott, and Co. is given in the text.

We should not be surprised if many readers interested in paper-making were to obtain a copy of this book on account of the last sections, devoted to the coating of photographic paper. The author rightly emphasises the absolute importance of the body paper, its cleanliness and freedom from iron and metallic particles. The use of baryta, or barium sulphate, is described, and also the special machinery for imparting the sensitised emulsion.

Taking the book as a whole, we are glad to recommend it to those associated with the paper industry. The average engineer of experience may not find much with which he is not already familiar, but to a large class of readers a book of this type must be welcome. It is copiously illustrated by drawings and diagrams, most of which have been supplied or lent by two Scottish engineering firms who understand the value of being obliging and courteous.

R. W. SINDALL.

The Structure of the Nucleus.

Cytology: With Special Reference to the Metazoan Nucleus. By Prof. W. E. Agar. Pp. xii+224. (London: Macmillan and Co., Ltd., 1920.) Price 12s. net.

CYTOLOGY as a science is of relatively recent growth, and its development was made possible only by improvements in the microscope. Yet the study of the details of cell structure and activity is now fundamental to almost every phase of biology. Nevertheless, biologists are too frequently content with a superficial or second-hand acquaintance with this fascinating field.

Previous to 1900 the process of mitosis had been investigated, the general constancy of the chromosomes from one cell generation to another was recognised, and their relations to fertilisation and reduction were understood in a general way, through the studies particularly of Strasburger and Hertwig: the foundations of the present cytology were laid. Synapsis had been recognised by Moore as a unique phase of the nucleus, and this led to a decade of active research by Farmer, Moore, Wilson, Strasburger, Grégoire, and a host of other plant and animal cytologists to elucidate the intricate course of events during the meiotic or reduction period.

But it is during the present century that improvements in method and increasing accuracy of observation have made possible the remarkable series of discoveries which have led to the present outlook on cytological problems. Particularly noteworthy has been the intimate linking up of the chromosomes with the problems of heredity, sex, mutation, and morphogenesis. This era of work began with the discovery of Montgomery in 1901 that the chromosomes in the nuclei of certain animals were in pairs, the members of which are respectively of maternal and paternal origin. Sutton in 1903 clearly established this relationship in an insect in which the chromosomes were of different sizes, and it is now a commonplace of observation in a large number of animals and plants. Several writers had already, shortly before the Mendelian phenomena became known, pointed out the theoretical possibilities for heredity which lie in the reduction division where the pairs of chromosomes are separated to enter different germ-cells. In the following two decades of research, the chain of evidence connecting the chromosomes with heredity and also with variation has drawn ever closer, until now the relationship must be regarded as definitely established.

One of the earlier stages in this proof was the discovery of the sex chromosomes in insects and afterwards in other animals. The initial suggestion of McClung, linking a particular chromosome with sex, was followed by notable discoveries by Wilson, Morgan, Doncaster, and a host of other investigators. Then a constant relationship between chromosome numbers and external characters was shown in the case of the Œnothera mutations; and still more recently the work of Morgan and Bridges on the non-disjunction of chromosomes and its relation to inheritance in Drosophila, combined with an enormous contemporary accumulation of collateral evidence of many kinds, has added the final link in the chain of evidence.

Recent work tends more and more not only to analyse the chromosomes themselves into their visible microscopic elements, but also to show the relationships which these bear to the hereditary Mendelian units. The chromatin morphology in related species is also being compared, and even chromosome phylogeny is no longer a visionary hypothesis.

All these and other recent developments in the field of cytology are admirably set forth in the work before us by Prof. Agar, who has thereby placed all biologists in his debt. The book will be chiefly useful to cytologists as a summary of the facts and the literature connected with a particular field—the nucleus in animals above the Protozoa. Within this purview are discussed many of the problems connected with nuclear structure. The author deals with mitosis and meiosis, syngamy and parthenogenesis, with a detailed discussion of these phenomena in various animal forms. He points out that the fundamental fact of meiosis is the segregation of the members of each pair of homologous chromosomes, and compares the parasynaptic and telosynaptic methods of meiotic pairing. We cannot agree with him that the telosynaptic method has been definitely disposed of, as it is still the best authenticated account in a number of plants and animals. Nor can we find any difficulty in the belief that both methods may exist in different organisms, a view first expressed ten years ago.

The account of meiosis in parthenogenetic eggs is welcome, but the discussion of the germ track in animals might have included a greater variety of forms.

The later chapters give a useful account of the sex chromosomes, theories of chromosome individuality and structure, and variations in chromosome number. An interesting chapter on heredity and morphogenesis considers the chromosome behaviour and sterility in hybrids, the cytological basis of mutation, and general questions

relating to the *rôle* of the nucleus and the chromosomes in development. Another section gives a short account of the chondriosomes, while the final chapter is concerned with the nucleus in the Protista and the nuclear relationships in plants.

The book is well illustrated and excellently produced. While it can scarcely appeal to a wide circle of readers, it will be of great service to all those who wish to be informed concerning the results arising out of the work of the last twenty years on this subject. The cytologist will find it indispensable for reference, and biologists generally will turn to it for the more recent work relating to these problems. R. R. G.

Our Bookshelf.

Aircraft in Peace and the Law. By Dr. J. M. Spaight. Pp. viii+233. (London: Macmillan and Co., Ltd., 1919.) Price 8*s*. 6*d*. net.

THIS is a useful attempt to put before the public the main issues of international law relating to the air. In every new development of modern invention, law-making authorities are faced with the difficult task of applying old principles to developments not contemplated when those principles were formulated, and with such a revolutionary departure as the modern aircraft there is a grave risk of deception by a false analogy. The British method has been to apply as far as possible the principles of the Merchant Shipping Acts to aircraft. The idea is lacking in boldness and imagination, for there is little parallel between the two forms of navigation in relation either to the problems of the navigators themselves, or to the rights and liabilities of the public at large. Generally speaking, however, a wise caution has been exercised by those who framed the International Convention. From another point of view the fundamental issue in aerial navigation is the sovereignty of the air, and on this England reserved her opinion. Continental Powers, without exception, clearly realising the serious military problems before them if all comers were allowed unrestricted flight above their territories, maintained in full their dominion in the air above their lands and territorial waters. England, on the other hand, had a different problem to face. No aerial highway of any importance crosses her frontiers in any part of the world, but nearly all the aerial routes which link up her scattered dominions do almost invariably cross the territories of other nations; she ought, therefore, her aerial experts maintained, to hold out for free flight.

It would seem that this view exaggerated the difficulties put in the way of innocent traffic by the maintenance of sovereignty, and minimised the dangers of sudden invasion. We must not forget that the economic interests of Great Britain are just as dependent on military security as they are on theoretical freedom of transport, and therefore Dr. Spaight would seem to be quite correct in urging the maintenance of the doctrine of the sovereignty of the air. Popular panic is a disaster only less serious than actual assault. The book is well arranged and indexed, while the writer's comments on what is as yet almost an untested department of law of exceptional difficulty, are acute, unprejudiced, and well-informed. W. B. F.

Wireless Telegraphy and Telephony: First Principles, Present Practice, and Testing. By H. M. Dowsett. Pp. xxxi+331. (London: The Wireless Press, Ltd., 1920.) Price 9*s*.

THE object of this work is to provide a connecting link between the various elementary textbooks, intended for those taking up the study of wireless telegraphy, and advanced treatises dealing with particular aspects or branches of the subject. It does not aim at completeness, but usefully develops certain parts of the theory and practice involved. The author insists upon an adequate appreciation of the structure of the atom and the part played by its constituents for a clear understanding of the phenomena met with in wireless working, and puts forward conceptions which, if not presenting a perfectly true scale model of the atom, at any rate are helpful in fixing the ideas. Another theoretical chapter leads up to explanations of some of the methods used in spark and continuous-wave transmission; and perhaps the most important sections of the book deal with the thermo-ionic valve and the modern methods of its employment for both reception and transmission, upon which so much of the recent advances depends. Other developments dealt with are high-speed automatic transmission and direction finding. A considerable portion of the book is devoted to systems of measurement of electrical quantities adapted to wireless telegraph testing. The author concerns himself only with up-to-date methods, and historical matter does not form part of his scheme.

Chimica delle Sostanze Esplosive. By Prof. Michele Giua. Pp. xvi+557. (Milano: Ulrico Hoepli, 1919.) Price 28 lire.

THIS treatise is written from the point of view of the laboratory chemist, and contains a very full account of the chemistry of explosive compounds. The author bases his work on that of Berthelot, and develops the theoretical treatment of explosive reactions on thermochemical lines. When dealing with the propagation of explosions through gases, the work of British investigators is practically unnoticed, and although a few references to papers do indeed appear in a table, they are omitted from the index. The treatment of this part of the subject thus appears to be rather superficial. The explosive compounds are described fully, and brief, but clear, accounts are given of the plant used in their manufacture. This section, with its numerous references to the litera-

ture, should prove of value to the organic chemist, but there is little attempt to compare the relative advantages of the compounds so described as constituents of technical explosives, and a comprehensive review of the whole subject is lacking. A later section contains the compositions of a large number of explosive mixtures, drawn mainly from the patent literature. It may be noted that, whilst many complex mixtures containing ammonium nitrate as their principal constituent are cited, there is no mention of the simple amatol mixtures which were so extensively employed during the war. The closing chapter describes the usual methods of testing explosives, and of performing the analysis of the raw materials and finished products. The illustrations include numerous photomicrographs of crystalline compounds, nitrated fibres, and prepared mixtures.

C. H. D.

Lad: A Dog. By Albert Payson Terhune. Pp. 309. (London and Toronto: J. M. Dent and Sons, Ltd., 1920.) Price 6s. net.

THOSE who like dogs will find this tribute very interesting, and will, we think, be able to confirm much of it from personal experience. Those who begin the book with a prejudice in the other direction are, we think, likely to change their position. The story is told enthusiastically, but there is no nonsense about it, and the anthropomorphism is restrained. Some comparative psychologists of the severer sort have said that the fatal thing is a personal interest in the creature observed, and the danger of mingling emotion with inference, and inference with observation, is well known. We might admit this, and yet hold that comparative psychology is likely to be advanced by intimate studies such as Mr. Terhune has given us of "Lad." There may be glimpses of reality to be got in this way which the analytic method does not reveal. In any case, the author has told, in a very delightful way, the story of a charming companion endowed with considerable complexity of character which nurture enhanced. For "Lad" was a "real" dog, and the chief happenings in nearly all the stories about him are "absolutely true." He lived out a full span of sixteen years, and his epitaph reads "Thoroughbred in Body and Soul."

A Theory of the Mechanism of Survival: The Fourth Dimension and its Applications. By W. Whately Smith. Pp. xi+196. (London: Kegan Paul, Trench, Trubner, and Co., Ltd.; New York: E. P. Dutton and Co., 1920.) Price 5s. net.

THERE is nothing striking or new in this argument, neither is there anything extravagant in its application. The author expounds in a clear and easy manner the familiar notions of flatland and of a possible fourth dimension, and suggests that a hypothesis is necessary to explain the somewhat doubtful phenomena with which psychical research deals. These notions, he thinks, afford the basis of a hypothesis.

London University Site and Needs.

I HAVE been surprised that no word of protest has been raised against the scheme of locating the University of London on a limited plot of land in the centre of the city. If the site were for administration purposes alone, combined, perhaps, with lecture-rooms for those subjects which require no practical instruction, the area offered might be adequate, but could only be rendered suitable for its purpose at such an enormous cost for site, removal of existing buildings, and erection of new edifices, that nothing but the most urgent necessity could justify; nor would the new position be one whit better or more convenient than South Kensington. It is, however, understood that the buildings to be erected are not only for administration purposes and lectures, but also to meet all requirements of the scientific departments.

Now it can be easily shown that provision for scientific subjects will require a far greater area of land than the amount suggested in the Government's offer. For the population of London one thousand would be a moderate estimate for the number of students who might be expected to need instruction in any one of the great departments of science, of which not fewer than twenty would need to be provided. Taking into consideration passages, staircases, preparation rooms, and assistants' rooms, for every working place in any practical department a floor area of at least ten square yards is wanted. Therefore, for each of the twenty subjects not less than ten thousand square yards of floor-space would be necessary. In addition to this, each will require lecture theatres, demonstration rooms, and research rooms; and for this, on a moderate estimate, we must add 50 per cent. to the above figure. This gives a total requirement for the twenty practical departments of not less than fifty acres of floor-space, in addition to the area wanted for administration purposes, libraries, museums, and for the subjects which do not need accommodation for practical work. Unless, therefore, the "skyscraper" system is to be utilised for university buildings, the 11½-acre plot proposed to be given up for the purposes of the University of London is absurdly inadequate, especially since not more than 8 acres of such a site could possibly be covered by actual buildings.

The problem is, however, much more complex than is represented by a mere computation of floor area. Anyone who has experience of a practical department knows the supreme importance of placing it in an entirely separate, self-contained building or institute, thereby allowing abundance of light for all rooms and furnishing space for any necessary future extension. Such institutes cannot be erected on a limited site. They require far more land than can ever be provided in the centre of a town. It is, therefore, certain that a single university adequate for the needs of London cannot be established in the situation proposed by the Government; and it is not too much to assert that its purchase and the cost of erecting buildings upon it would be a most wasteful expenditure, involving at the lowest estimate a total of five millions sterling!

The alternative is to decentralise the teaching by placing several university centres—say four to begin

with—on the outskirts of London in places where each could be furnished with at least one hundred acres of land at a total cost of no more than is asked for the 11½ acres now proffered.

The advantages of such outlying centres would be: (1) The students could live in the neighbourhood of the institution, either at home or in hostels, and would not be compelled to take a long journey twice a day. (2) There would be abundance of room for all purposes, including recreation. (3) Each subject would be able to have its own area of ground for the erection of a suitable institute, and for permitting future extension. (4) Temporary buildings might be put up until experience has shown what character of permanent buildings ought to be erected. (5) The classes would not be of an unwieldy size; for we might assume for each of the four centres two hundred and fifty students, instead of the one thousand assumed for the central institute, *i.e.* for each practical subject.

American experience has shown that one hundred acres is not too much land to provide for the buildings of a modern university, and a scheme which assumes that a single university for a city the size of London can be accommodated in a space of ten, or even twenty, acres is self-condemned at the outset.

University New Buildings, Edinburgh, June 7.

High Rates of Ascent of Pilot-Balloons.

ABNORMAL rates of ascent shown by pilot-balloons have in recent years aroused considerable interest amongst aerologists. These digressions were mostly ascribed to the occurrence of vertical air-currents, but three years ago Wenger (*Annalen der Hydrographie*, 1917, Hamburg) suggested[1] that, for the greater part, the observations did not permit of such an explanation. He advanced the theory that these abnormal rates were chiefly caused by increased turbulence of the air; and he stated, making use of the Lindenberg material, that the rates observed depended on different conditions of the air, as wind, friction, etc., which, no doubt, must have a notable influence on its turbulence.

In the same journal, however, it was shown that a large number of observations made at Sofia (Bulgaria) gave strong evidence that actually large vertical air-currents had occurred, and that the high and low rate should, without doubt, be ascribed to upward and downward movements of the air.

Between 1912 and 1917 much material regarding these rates was gathered by the Batavia Observatory, and peculiar circumstances make this material of critical value, for it consists of three series taken in three localities differing in character, the ascents being made at various hours during the day and night.

The first series was taken at Batavia during the dry, sunny season, when land- and sea-breezes are developed strongly; and the second at Bandung, a town situated on a plateau 700 m. above sea-level, surrounded by mountains. Insolation in the latter case did not differ much from that at Batavia; the mountain- and valley-breezes were only slight.

The third series was taken by Dr. Boerema on a small coral islet in the Java Sea at the end of the west monsoon. There the influence of insolation and of land- and sea-breezes is practically nothing.

Most of the balloons were observed from two points; also, up to 1 or 1½ km., half-minute readings were taken between the usual observations made every minute. Balloons of different weight and pattern were used; those for the night carried a second balloon filled with acetylene and a burner. For each kind I calculated the average rate observed at the level of 3 or 4 km., and derived from it the rate for the layers beneath by applying the formula

$$v = ad^{-\frac{1}{3}} \ (d = \text{air density}).$$

For the light balloons there remained, of course, a change of rate with height, which, however, I was unable to calculate, but I surmise was small.

The accompanying diagram (Fig. 1) gives for the lowest layers up to 3 km. the departures of the mean rates observed from those at 3 or 4 km. Evidently it displays the contrast between the land and the sea influence, *i.e.* on land the rates are increased by day, but are normal by night, while at sea there is no distinct increase in the average rate.

At Batavia the positive digression runs parallel with the strength of the sea-breeze and with the change of

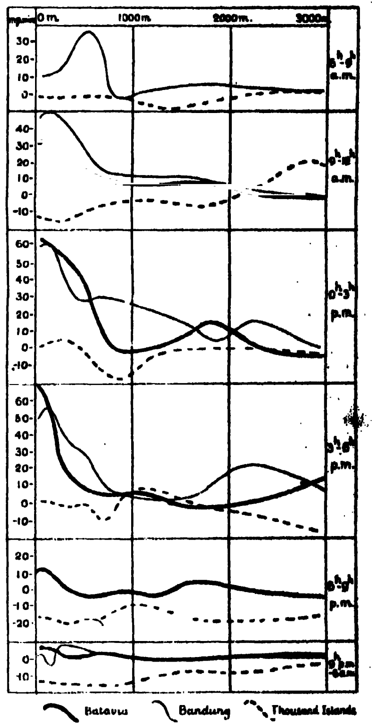

FIG. 1.

wind velocity caused by the Espy-Köppen effect. At Bandung also this parallelism seems to exist.

Consequently, at first sight, the explanation proposed by Wenger might be given: During the day turbulence is enhanced on land by increase of wind velocity, by friction with the surface, and by insolation; at sea, on the contrary, these causes are not present. However, on more detailed examination this explanation is not confirmed. Thus the rate of ascent did not prove to depend on wind velocity, as the following figures clearly show:

Batavia.

9 a.m.–noon		Noon–3 p.m.		3–6 p.m.	
Δ Rate of ascent m. p. min.	Wind velocity m. p. sec.	Δ Rate of ascent m. p. min.	Wind velocity m. p. sec.	Δ Rate of ascent m. p. min.	Wind velocity m. p. sec.
3	3·8	−4	8·7	4	8·0
63	4·0	−64	7·5	56	5·6
—	—	136	6·4	133	6·9

[1] It came under my notice only a few months ago.

Bandung.

Δ Rate of ascent m. p. min.	Wind velocity m. p. sec.
	9 a.m.–6 p.m.
10	2·9
39	3·7
103	2·3

Also, the wind velocity scarcely ever reached the values (>15 m. per sec.) at which, according to Wenger, the influence of wind velocity begins to increase turbulence, so that a notable increase in the rate of ascent is to be expected.

Moreover, insolation is strongest between 9 a.m. and noon; afterwards, clouds mostly weaken it or prevent further increase. On the other hand, the rate of ascent at Batavia between noon and 3 p.m. considerably exceeds that between 9 a.m. and noon.

Thus an explanation of the observed rates by Wenger's theory practically fails; on the contrary, the supposition of vertical air movement is tenable.

For some years I supposed that the air had to rise in columns, and, the surrounding air being sucked in, the balloon in most cases would also be sucked in, and afterwards would not leave the ascending air-columns. Later I read that J. S. Dines was inclined to this conception. The criticism of this view offered by Wenger must be accepted; but why should not both causes co-operate in the lowest strata?

Indeed, I have found that my results and those of Wenger coincide regarding the change of rate of ascent when, passing upwards, wind velocity varies.

Denoting this change by $10^2 \frac{dv}{dz}$ (v = wind velocity in m. per sec., and z = height in m.), I found:

Batavia.

$10^2\frac{dv}{dz}$	Δ Rate of ascent m. p. sec.	No. of cases
1·2	0·7	22
−1·1	−1·0	42
−2·2	−0·6	20

Thousand Islands.

$10^2\frac{dv}{dz}$	Δ Rate of ascent m. p. sec.	No. of cases
0·7	1·3	28
−0·4	−1·1	38

As these values show, the change of rate with wind velocity is not developed strongly, the percentage of cases in which dv/dz and Δ rate were of the same sign being respectively for Batavia and the Thousand Islands 63 and 68 only.

Finally, we are obliged to accept the view that in the sea-breeze the air must rise as the breeze dies out at a moderate distance from the coast. Also, the air seems to rise no higher than the sea-breeze itself, the rate of rise diminishing with its horizontal velocity.

Moreover, I think the material collected on and near Java is not favourable to the idea of such a preponderating influence of turbulence as Wenger accepts; on the contrary, it corroborates the assumption of ascending columns.

The formation of the fine-weather cumuli, to be observed every sunny day in the tropics, is clear evidence of the general occurrence of these ascending air columns.

W. VAN BEMMELEN.

A New Method for Approximate Evaluation of Definite Integrals between Finite Limits.

GAUSS, I believe, gave a very large number of forms for approximate evaluation of definite integrals between finite limits. His formulæ are all based, like Tchebycheff's rules, on the assumption that the integrand is expressible approximately by a finite number of terms of the series $a+bx+cx^2+dx^3+\ldots$. His plan was to use a minimum number of suitably weighted ordinates to give him the exact value of the integral for a specified number of terms.

Taking the range of integration to be from −1 to +1, which can be done without any loss of generality, his simplest integral is

$$\int_{-1}^{+1} f(x)dx = f(-x_1)+f(x_1),$$

where

$$x_1 = \sqrt{\tfrac{1}{3}}.$$

This formula with two ordinates gives *exact* values for

$$\int_{-1}^{+1}(a+bx+cx^2+dx^3)dx,$$

and is in that respect on a par with Simpson's formula, which has three ordinates weighted in the proportions 1, 4, 1, and situated at the ends and middle of the range.

The next Gauss formula is

$$\int_{-1}^{+1} f(x)dx = \tfrac{1}{9}\{5f(-x_1)+8f(0)+5f(x_1)\},$$

where

$$x_1 = \sqrt{\tfrac{3}{5}}.$$

This is exact up to and including the term in x^5 in the series. Put in the same form as Mr. Merchant's formula (which is also exact up to the x^5 term) in NATURE of June 3, it becomes

$$\int_0^1 f(x)dx = \tfrac{1}{18}\{5f(x_1)+8f(x_2)+5f(x_3)\},$$

where

$$x_1 = 0{\cdot}1127, \quad x_2 = 0{\cdot}5, \quad x_3 = 0{\cdot}8873.$$

The third formula is

$$\int_{-1}^{+1} f(x)dx = \frac{1}{(A+B)}\Big[Af(-x_1)+Bf(-x_2)+Bf(x_2)+Af(x_1)\Big]$$

where

$$A = \tfrac{1}{2}-\tfrac{1}{6}\sqrt{\tfrac{5}{6}}, \qquad B = \tfrac{1}{2}+\tfrac{1}{6}\sqrt{\tfrac{5}{6}},$$
$$x_1^2 = \tfrac{3}{7}+\tfrac{2}{7}\sqrt{\tfrac{6}{5}}, \qquad x_2^2 = \tfrac{3}{7}-\tfrac{2}{7}\sqrt{\tfrac{6}{5}}.$$

Transferred to the other form, this becomes

$$\int_0^1 f(x)dx = 0{\cdot}1739f(x_1)+0{\cdot}3261f(x_2)+0{\cdot}3261f(x_3)+0{\cdot}1739f(x_4)$$

where

$$x_1 = 0{\cdot}0694, \quad x_2 = 0{\cdot}3300, \quad x_3 = 0{\cdot}6700, \quad x_4 = 0{\cdot}9306.$$

This formula is exact up to and including the term in x^7.

It may be noticed that although the weight factors are now incommensurate, they can be written with a very close degree of approximation as $\frac{4}{23}$ and $\frac{15}{46}$, and the integral then takes the form

$$\int_0^1 f(x)dx = \tfrac{1}{46}[8f(x_1)+15f(x_2)+15f(x_3)+8f(x_4)].$$

Possibly Mr. Merchant might find that this form would be useful in ship design. The positions of the ordinates is not sufficiently close to even tenths to permit of such further modifications being made, but if the ship's half-length were divided into fifteen sections, the ordinates would come very near the first, fifth, tenth, and fourteenth. Some of the higher Gauss integrals might be found to fit in even more conveniently.

THOS. Y. BAKER.

Admiralty Compass Observatory, Slough, Bucks, June 10.

The Royal Military Academy.

SIR GEORGE GREENHILL, in an article in NATURE of April 29, entitled "Artillery Science," passes severe strictures on the Royal Military Academy—"The Shop." These reflect on the whole staff, especially the military staff, and as the officers are not permitted

to defend themselves in public journals, I ask permission as a civilian to say a few words in defence.

War is the best test of a military establishment. During the war the R.M.A. worked continuously, and turned out more than two thousand young officers who were able to proceed, either direct or after a short additional course, straight to the battlefields and take their full share of the work with their batteries or field companies. Courses in field telephony were also given to an equal number of officers, n.c.o.'s and men of the new armies at a critical period when there were few instructors elsewhere. There were many other activities. Owing to the seclusion in which the Academy works, there were few except those immediately connected with it who had any idea of the great amount of work actually done.

Science was encouraged by all three of the Commandants during this period, and dealt with all military applications up to date. The teaching of wireless was commenced in the R.M.A. eighteen years ago, and that it was not used at a much earlier period of the war was certainly no fault of the R.M.A. During the war an opportunity was given for the study in detail of the course given to French artillery officers. In science there was nothing to be learnt from it, and the same was reported in other subjects. There is no reason to believe that the German schools were any better.

The R.M.A. has been submitted to inquiry from outside three times in the past twenty years: First, by Lord Esher's Committee shortly after the Boer War; next, in 1911, an inspection by specialists from the Board of Education; and thirdly, an inspection by the Board of Education in February last. The first two reports were entirely favourable, and no doubt can still be obtained. The latest, which is not yet permitted to be published, gives a fair picture of the place and its work. It also contains criticisms and recommendations which, if adopted by the War Office, would improve the establishment, and consequently the Army. I understood from the inspectors that they had come to the same conclusion as those on a former occasion, viz. "The Academy is very efficient."

The academy is not perfect, but its improvement, not its abolition, is what is desirable. Merely to move it to a new situation while retaining the old system would do no good; and to amalgamate it with Sandhurst would, in my opinion, in these specialising days, be a mistake.

Improvements must commence at Whitehall, for it is at the War Office that all decisions as to courses of study, staffs, etc., are made. Scientific advisers from the learned societies would help, for it is scarcely to be expected that the officers there can be in touch with scientific progress. There are still some who do not yet believe in the importance of science, and are under the impression that any R.E. officer can teach all that is necessary.

The half-dozen civilians mentioned in the article are responsible for mathematics and science. They must now be almost alone amongst those engaged in education in the public service in having no security of tenure and no retiring allowance. Their numbers, now reduced below pre-war level, might be increased with advantage, but I understand that it has been decided to dispense with civilians in science altogether in a year or so, and no doubt the mathematical staff will follow. Their places will be filled by officers. I think that most of those who have an intimate knowledge of these subjects will agree that this is a retrograde step.

Mathematics and science should have adequate civilian staffs of properly trained men. Appointments should be permanent and emoluments correspond to those of the military staff, with retiring allowances on the Civil Service scale. Members of the civilian staff could then, without anxiety, devote themselves to the work, which necessarily takes a different direction from that at a civil institution, and even the best civilians require a considerable time before becoming familiar with military requirements and military apparatus.

Accommodation for research by the staff should be provided. Officer instructors, in science at least, should be students as much as instructors, so that at the end of their appointments they would rejoin the Army reasonably up-to-date in their subjects. Cadets with a special bent should be given opportunities so far as possible to do extra work, to assist them in deciding on their future course and to prepare them for it. The present two years' course is too short to do much in any direction, as it has to be divided between many subjects. An increase of length would be an advantage.

The R.M.A. is a cadet school, and aims at producing the useful regimental officer, but it cannot produce experts. For the artillery there should be a further selection of young officers, who should receive additional training at the Ordnance College, which should be a genuine artillery university, and not merely a training place for officers desirous of semi-civil appointments. It should be the function of this establishment to turn out the artillery expert, and if it were not done the blame would lie there. The R.E. would probably require a similar establishment or an extension of the "School of Military Engineering." Co-operation between the various military schools is advisable, but, above all, there should be some system established for the regular distribution of information on military matters amongst the departments concerned. At present it is exceedingly difficult for those engaged in one department or school to find out what is happening elsewhere.

The equalisation of pay will now enable cadets to make a free choice between the R.A. and the R.E., but those scientifically inclined will still probably choose the latter.

I do not believe much is to be gained by imitating foreign institutions. In the four years and a half of the war we succeeded in overtaking the German in every direction, in spite of his long preparation. Our aim now should be to avoid retrogression; for that is our chief danger.

J. YOUNG.

Science Department, Royal Military Academy,
Woolwich, S.E.18, June 3.

The Separation of the Isotopes of Chlorine.

ON certain plausible assumptions concerning the nature of chemical equilibria and the properties of isotopes, it should be possible to separate the isotopic varieties of an element like chlorine by means of a reversible chemical change in the gaseous state, provided that the number of atoms of chlorine in the reacting compound is unequal to the number of atoms in the resulting compound.

Thus, for the sake of argument, assume that chlorine contains two isotopes the atoms of which can be represented by Cl and Cl′, then there would be three classes of molecules, namely, Cl_2, Cl_2', and ClCl′, of which the corresponding liquids and solids would have the very nearly same vapour pressure at the same temperature. Accordingly, if it may be assumed that 2 mols. of ClCl′ can be converted into 1 mol. of Cl_2, and 1 mol. of Cl_2' in the liquid forms at the same temperature without the expenditure of work,

$$[Cl_2][Cl_2'] = [ClCl']^2, \quad \ldots \quad \text{(i.)}$$

where the square bracket has the usual significance of concentration.

Now in Deacon's process, which is represented by the chemical equation

$$4HCl + O_2 = 2H_2O + 2Cl_2,$$

we should have

$$\frac{[Cl_2]}{[Cl_2']} = \frac{[HCl]^2}{[HCl']^2}, \quad . \quad . \quad . \quad . \quad \text{(ii)}$$

Taking $\frac{[HCl]}{[HCl']}$ as 3, $\frac{[Cl_2]}{[Cl_2']}$ is 9, provided that the temperature and concentration of the oxygen are selected so that the concentration of the chlorine is small at equilibrium.

But the ratio of the atoms of the two varieties of chlorine is given by

$$\frac{[Cl_2] + \frac{1}{2}[ClCl']}{[Cl_2'] + \frac{1}{2}[ClCl']},$$

and this, by equations (i.) and (ii.), is equal to $\frac{10 \cdot 5}{2 \cdot 5}$, which differs appreciably from 3.

Deacon's process is selected merely for the purpose of illustration.

If the isotopic varieties of chlorine are inseparable by the method above indicated, it is clear that

$$\frac{[Cl_2] + \frac{1}{2}[ClCl']}{[Cl_2'] + \frac{1}{2}[ClCl']} = \frac{[HCl]}{[HCl']} = \frac{[Cl_2]^{\frac{1}{2}}}{[Cl_2']^{\frac{1}{2}}}, \quad \text{(iii.)}$$

whence

$$2[Cl_2]^{\frac{1}{2}}[Cl_2']^{\frac{1}{2}} = [ClCl'] \quad . \quad . \quad . \quad . \quad \text{(iv.)}$$

Now consider two solids composed entirely of Cl_2 and Cl_2' molecules respectively. The vapour pressures of the two solids will be very nearly (if not exactly) the same—say p—at the same temperature t.

Evaporate a gram-molecule of both the solids. Reduce the pressure of the Cl_2 isotope to p_1, and that of the Cl_2' isotope to p_2, and then introduce both unsaturated vapours into a van't Hoff's equilibrium box. The total work done in these operation is

$$Rt \log_e \frac{p^2}{p_1 p_2}.$$

Now remove 2 gram-molecules of the ClCl' variety (which from equation (iv.) will obviously be at the pressure $2\sqrt{p_1 p_2}$) from the equilibrium box. Increase the pressure to p, and finally condense at this pressure to the solid form. The work done during this series of operations will be

$$Rt \log_e \frac{4p_1 p_2}{p^2}.$$

Therefore the total work performed in effecting the change represented by the equation

$$Cl_2 \text{ (solid)} + Cl_2' \text{ (solid)} = 2ClCl \text{ (solid)}$$

is $Rt \log 4 = A$.

But it is difficult to understand how the free energy A could differ appreciably from zero if the molecular heats of the three varieties of chlorine are nearly the same—as they are generally supposed to be—and if the entropy of the reactants Cl_2 and Cl_2' is equal to that of the resultant 2ClCl' at the absolute zero temperature, as Nernst postulates in his heat theorem.

An attempt is being made in the Jesus College Laboratory to separate the isotopes of chlorine by a method similar to that given above. A negative result would be difficult to reconcile with Nernst's theorem that $\frac{dA}{dt} = 0$ at the absolute zero.

D. L. CHAPMAN.

Jesus College, Oxford.

A Note on Telephotography.

HAVING examined a number of formulæ for the circle of illumination in telephotography, and found them all to be inapplicable in certain cases, I propose the following, which seem reasonable and are applicable in all cases. These formulæ are particularly vital in the line along which telephotography is at present developing.

Let C_F = Full circle of illumination.
C_E = Circle of equal „
C_M = Mean circle of „
M = Magnification.
f_1 = Focus of positive lens.
f_2 = „ negative
b = Diameter of positive lens.
c = „ negative „

Then

$$C_F = \frac{M^2(f_1 c + f_2 b) - Mf_2 b}{M(f_1 - f_2) + f_2} \quad . \quad . \quad . \quad (1)$$

$$C_E = \frac{M^2(f_1 c - f_2 b) + Mf_2 b}{M(f_1 - f_2) + f_2} \quad . \quad . \quad . \quad (2)$$

$$\frac{M^2 f_1 c}{M(f_1 - f_2) + f_2} \quad (3)$$

The last formula (3) is not only the simplest, but it is also the accurate value for the circle when the aperture (b) of the positive lens is small. It is the mean between the full (1) circle and the evenly illuminated (2) circle. The first (1) is the most usually used. It gives the diagonal of the largest plate that can be employed. The second (2) gives the circle that is equally illuminated. If it is possible to make the aperture (b) of the positive lens equal to the diameter (c) of the negative lens, this formula becomes the simplest.

$$C_E = Mc.$$

I have received an opinion on the above from a distinguished authority upon geometric optics. He is of the opinion that it is necessary to add that certain assumptions have been made in deciding these formulæ. These assumptions are (α) that the lenses are thin, (β) that the aberrations may be neglected, and (γ) that the focal lengths of both lenses, f_1 and f_2, are definite quantities.

(α) Photographic positive lenses are usually not thin. Negative telephoto lenses, except some high-power lenses, are always thin. With a thick lens the "equivalent planes" for the two sides (the "object space" and the "image space") are different. As all measurements in the above formulæ are made from the back of the positive lens and the front of the negative lens, no confusion can arise between the equivalent planes.

(β) The aberrations of a photographic lens are negligible.

(γ) The positions of the equivalent planes of the negative lens move over a small space with a change of magnification. This quantity is negligible in deciding the circle of illumination, which does not need to be known exactly.

The position of the equivalent plane of the whole varies greatly with a change of distance of object. This can be completely corrected by substituting the "back conjugate focus" of the positive lens for the distance, in place of the "principal" focus (f_1) in the above formulæ. In telephotography the object is usually "at infinity," and this correction is not necessary.

In a short note it is not possible to do more than indicate the conditions in which these formulæ may be used. Consult Lan-Davis on "Telephotography" and Beck and Andrews's "A Simple Treatise on Photographic Lenses" (Appendix) for "equivalent planes."

A. B.

Recent Researches on Nebulæ.[1]

By MAJOR WILLIAM J. S. LOCKYER.

THE latest volume (No. xiii.) in the series of Publications of the Lick Observatory, situated on Mount Hamilton, California, is completely devoted to a series of well-laid-out investigations of the study of the forms, distribution, velocities, and spectra of the nebulæ. The volume is one of extreme interest and importance, and will become a classic for a considerable time on those interesting objects scattered throughout the heavens.

In these days, when the study of the evolution of the stars is occupying a position in the front rank, the more detailed information of the nebulæ, their composition, structure, and movements, is of fundamental importance, for these bodies are criteria in the evolutionary stages of stars.

Considerations of space will not permit here more than an outline of the contents of this substantial volume, which includes six separate contributions, each devoted to a special research, and a large number of beautifully reproduced plates.

Part i. is contributed by Mr. H. D. Curtis (pp. 11–42), and deals with the descriptions of 762 nebulæ and clusters photographed with the Crossley reflector. It comprises all photographs of these objects which have been taken with this instrument since the year 1898, when systematic work was commenced, forming, therefore, a valuable homogeneous research.

It is interesting to note the types of the 762 entries, which Mr. Curtis divides as follows: 513 spiral, 56 diffuse, 36 globular, 24 sparse, 78 planetary, 8 dark, and 47 unclassified. Mr. Curtis is led to believe that all the many thousands of nebulæ not definitely to be classed as diffuse or planetary are true spirals, and that "the very minute spiral nebulæ appear as textureless discs or ovals solely because of their size."

In estimating the probable total number of the spiral nebulæ, Mr. Curtis concludes that at least 700,000, and very probably 1,000,000, small spirals are within the reach of large reflecting telescopes. A chart showing the distribution of regions on which small nebulæ were counted indicates also the position of the galactic plane, and the paper concludes with reproductions of a few typical nebulæ.

The second part, by the same author, is devoted to a study of occulting matter in the spiral nebulæ (pp. 45–54), and its object is to show that the occurrence of such dark bands running down the length of spiral nebulæ seen edgewise is a relatively common feature. While a description of these appearances is not necessarily satisfactory to those who have not had occasion to observe them or to see the original photographs, Mr. Curtis includes seventy-seven reproductions. By the kindness of Prof. W. W. Campbell, reproductions of some of these spirals are here given (Figs. 1, 2, and 3).

References are made to other evidences of occulting matter in the sky, such as the cutting off in the number of stars round a nebula, "coal sacks" or starless regions, dark nebulæ, etc. (see Fig. 4). The fact that many spectroscopic binaries indicate a constant radial velocity for the H and K lines, different from the periodic shift of the other lines in the spectrum, suggests, according to the author, the interposition between us and the binary of a cloud of non-luminous matter, though, as he says, there are some difficulties in this hypothesis. The subject of the peculiar grouping of the

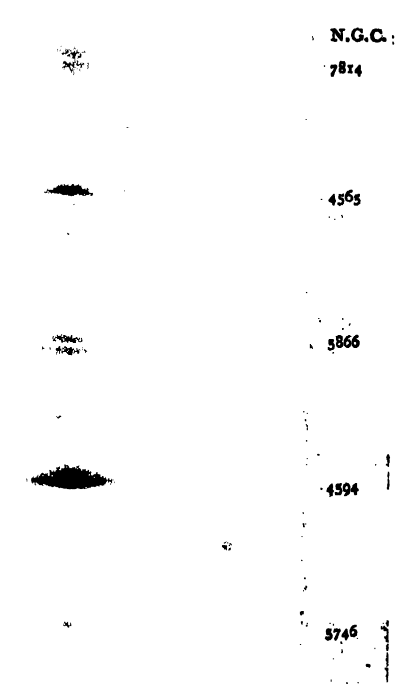

FIG. 1.—Spiral nebulæ seen almost exactly edgewise and showing indubitable evidence of dark lanes. (H. D. Curtis.)

spiral nebulæ about the galactic poles is also mentioned.

Part iii. is entitled "The Planetary Nebulæ," and in it Mr. Curtis brings together the results of a research on a series of photographs of all the planetary nebulæ north of 34° S. declination. Seventy-eight of these objects are dealt with, and they are all reproduced either by photographs or by drawings (with scale). Drawings were resorted to only when the objects were so small that they could not be reproduced by the process of photo-engraving, or when great differences in brightness between the central and the faint outlying portions were encountered, which

[1] University of California Publications. Publications of the Lick Observatory. Vol. xiii. Pp. 268+50 plates. (Berkeley: University of California Press, 1918.)

prevented an adequate representation of all the details of the nebula (Fig. 5). This collection of illustrations, showing the forms assumed by the planetary nebulæ, will throw considerable light upon the structure and life-history of these bodies. An important addition to the illustrations is that the exposure for recording a selected portion of the Orion nebula has been used as a standard, and the time necessary for recording the brightest portion of a planetary nebula is given in relation to that standard. Thus an approximation to the relative brightness of the planetary nebulæ is secured.

With regard to the distribution of these nebulæ in space, an interesting diagram of which is given, Mr. Curtis finds that the smallest objects are almost invariably in, or very close to, the Milky Way, while the larger planetaries, "the giants of the class," somewhat more frequent in the vicinity of the galactic plane, are, "on the whole, fairly uniformly distributed over the entire sky." It is concluded, therefore, that these giants may be in the Galaxy, but the nearest to us, and, therefore, would only appear outside, and he suggests their inclusion in parallax programmes, as many of them have central stars sufficiently bright for that purpose.

Further reference cannot be made here to this interesting paper except to add that the author classifies the planetary nebulæ according to their appearances, and then discusses these forms in relation to homogeneous oblate spheroidal or homogeneous truncated spheroidal shells under various conditions.

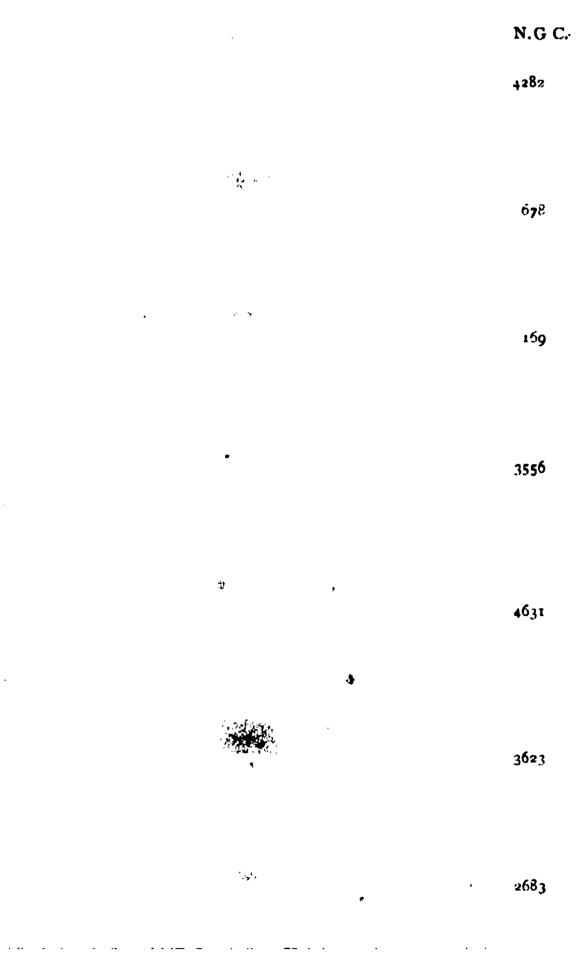

FIG. 2.—Spiral nebulæ seen almost, but not exactly, edgewise, and some the planes of which make a small but appreciable angle with the line of sight, showing clear evidence of dark lanes. (H. D. Curtis.)

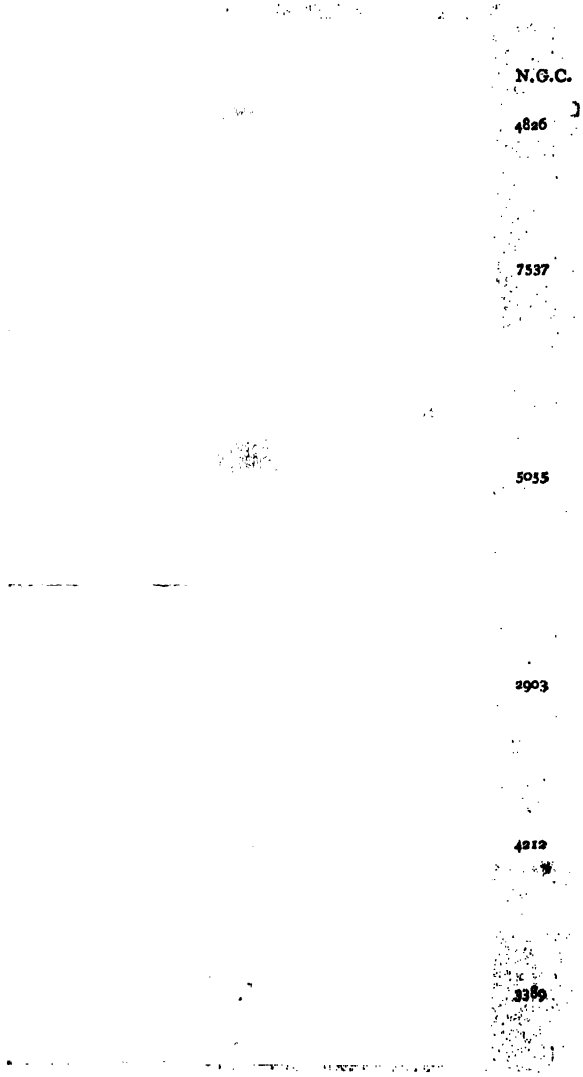

FIG. 3.—Spiral nebulæ making a much greater angle with the line of sight, showing clear-cut dark lanes (2903, 4212), and a line absolutely black and cutting across, a whorl at the right end (4826). (H. D. Curtis.)

Prof. W. W. Campbell and Mr. J. H. Moore are the authors of part iv., which is devoted to the spectrographic velocities of the bright-line nebulæ (pp. 77–183). The observations are a combination of those made with the 36-in.

refractor at Mount Hamilton and with the 37-in. Mills reflector at Santiago, Chile, and they were commenced in the year 1913. The list includes 138

FIG. 4.—A "dark nebula" (17h. 57m., −27°50′) visible through its projection upon the background of stars, and not considered to be "a hole" in the Milky Way. Note the circular protuberance at the south-west corner, as clear-cut as an ink-drop and perfectly dark. (H. D. Curtis.)

nebulæ with bright lines in their spectra. In the earlier part details are given with respect to the spectroscopes employed, the probable errors of the results, and a description of the observations made at the two stations.

The detailed results of each object are then given in the order of right ascension. Attention may be directed to the fact that the lengths of the slits of the spectroscopes employed were in most cases more than sufficient to cover the width of the images of the objects photographed, so that the spectra of the central and outlying portions of the nebulæ should both be recorded.

In a further table the final deduced radial velocities of each object observed are given. The observations recorded are evidence of most extensive and arduous work, and the numerous observations of each object considerably emphasise

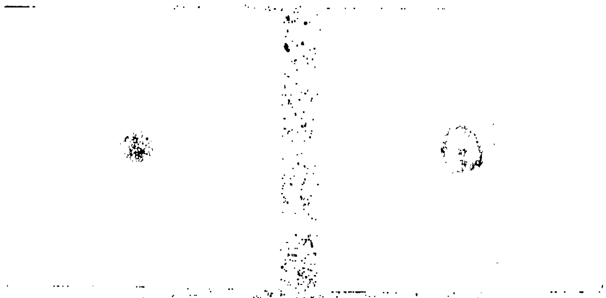

FIG. 5.—On the left a photograph of N.G.C. 2392, a double-ring planetary nebula; and on the right a composite drawing of the same made from several photographs to show details of the structure not attainable from any single photograph. (H. D. Curtis.)

this fact. The accompanying illustration (Fig. 6) shows a photograph of the chief nebular line in N.G.C. 2392, and exhibits the kind of structure displayed from which the internal motion of the nebula was deduced.

The average magnitudes of the derived values for the velocities are as follows:—Calling the nebulæ less than 5 secs. in diameter "stellar," and those greater than 5 secs. "non-stellar," the mean velocity for thirty-one "stellar" nebulæ is 28 km. per sec., and for sixty-five non-stellar nebulæ 31 km. per sec. with reference to the stellar system. For evidence of rotation or internal motion in the planetary nebulæ, the lines in the spectra of forty-six such objects have been examined in detail and are here discussed. Of these, twenty-five gave evidence of internal effects, while nineteen, and possibly two more, indicated rotations about axes roughly perpendicular to the line of sight. It is worthy of note that the most elongated planetary nebulæ showed the highest rotational speeds.

The study of the radial velocities of numerous parts of the Orion nebula shows a range in velocities from +9·7 km. to +24·9 km., and, as the authors state, the results do not favour the hypothesis of a rotation as a whole, but the observed differences appear to be local or regional in character.

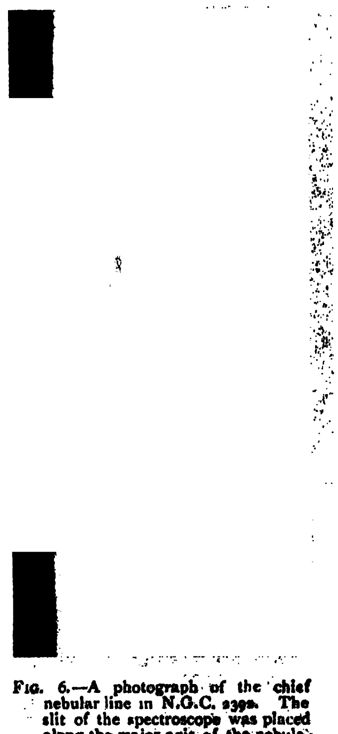

FIG. 6.—A photograph of the chief nebular line in N.G.C. 2392. The slit of the spectroscope was placed along the major axis of the nebula. (W. W. Campbell and J. H. Moore.)

Mr. R. E. Wilson contributes part v. of this volume (pp. 187–90), which deals with the radial velocity of the greater Magellanic cloud. In 1914 it was pointed out that several gaseous nebulæ in this region exhibited very large and approximately equal radial velocities, so Mr. Wilson presents the results of his study of the cloud as a whole. The author upholds this view after his survey, for he finds that, observing seventeen planetary nebulæ in this region, the radial velocities lie between +251 km. and +309 km., an average of +276 km. Correcting this mean for solar motion, the mean velocity is +261 km. per sec. This average, compared with the mean velocity deduced in part iv. for other planetary nebulæ, points to

exceptional conditions in this region. Mr. Wilson refers to the spiral appearance of this great cloud and to the high velocities observed in spiral nebulæ, nebulæ which may be considered as isolated island universes similar to our Milky Way system, suggesting that the great cloud may afford an opportunity for the study of detailed characteristics of spiral nebulæ.

Part vi., the last of the series of the important contents of this volume, is contributed by Mr. W. H. Wright, and deals with the subject of the wave-lengths of the nebular lines and general observations of the spectra of the gaseous nebulæ (pp. 193–268). The matter falls under three headings: (1) The measurement of wave-lengths and the intensities of the nebular lines; (2) the study of the nebular nuclei; and (3) the investigation of the distribution of nebular radiations throughout the nebulæ; and is accompanied by a series of plates, which demonstrate, more than text can do, the fine definition and great scale of the photographs of the spectra of the nebulæ which served as his data. Fig. 7 is an illustration of the spectrum of N.G.C. 6818, taken with the slitless spectrograph with an exposure of four hours. It does not seem that the statement could be contradicted that the wave-lengths and intensities of the nebular lines deduced will be used as a standard in this branch of physical astronomy for some time.

This research is very opportune, because more detailed facts were required to help in the unravelling of the relationships between nebulæ as such, nuclei of nebulæ, and bright-line stars such as Wolf-Rayet stars. As the whole problem of the nature of stellar evolution is that of the solution of the relationship between nebulæ and stars, the study of the question is of vital importance. The idea of a falling temperature continuing throughout the whole life-history of a star has more recently given place to the hypothesis, apparently a very natural one, of a star in its early career increasing in temperature, reaching a maximum of development and temperature, and afterwards cooling until the invisible stage is reached. In the light of these hypotheses Mr. Wright, as the result of his research, expresses his view as follows:—

There are at present two general conceptions as to the nature of stellar evolution, one of which assumes a falling temperature throughout the period of a star's development, while the other predicates a rise to maximum and a subsequent decline; both of these views assume the nebula as the primordial state. As between these two hypotheses, the present observations undoubtedly favour the first, since they add to the proof that the gaseous nebulæ are associated only with the hot stars.

While the above is one of the main conclusions derived by Mr. Wright from this research, there are many other points of particular interest to which limitations of space forbid reference in this article.

It is interesting to compare a direct photograph of a nebula with its spectrum taken with a slitless spectrograph. Nebulæ when photographed with the latter instrument present remarkable varieties of form and size corresponding to different nebular lines in the spectrum, while the direct photograph shows only a form resulting from the integration or the fitting together of the component images of the different forms and sizes. The prismatic images afford a means, therefore, of detecting the differences in distribution of the component gases of the nebula, and indicate that the view of a nebula in a telescope or on a direct photograph is not the best means of studying the complex structure of these bodies.

In conclusion, it may be stated that this addition to the University of California Publications is a valuable contribution, and sustains the high standard of the researches which emanate from the Lick Observatory under the able directorship of Prof. W. W. Campbell.

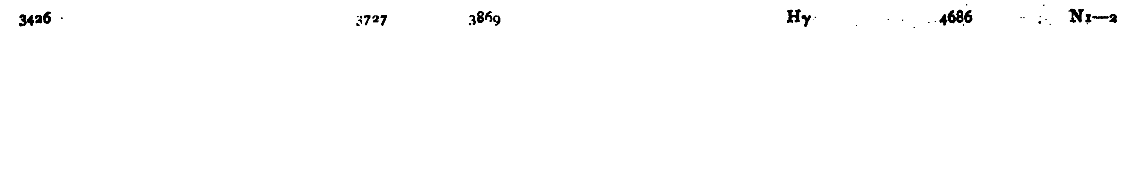

FIG. 7.—The spectrum of N.G.C. 6818, which records images of a variety of shapes and sizes, most of them having the appearance of a horse-shoe, the open end of the shoe lying to the north. Some of the images show mottlings or condensations scattered along the shoe or ring. (W. H. Wright.)

The Importance of Meteorology in Gunnery.

By DR. E. M. WEDDERBURN.

AT the commencement of the war the knowledge of the effect of wind and of the density of the air on the flight of a shell was elementary. It was assumed by the gunners that the wind was of the same direction and strength at all heights reached by the projectile, and that the density of the air decreased with altitude according to an artificial convention. The corrections for wind and density which the gunner was taught to apply were supposed to be referable to the meteorological conditions observed by him at the battery, but he was not taught how

these conditions should be observed, nor that the observation of surface air temperature was an exceedingly difficult matter.

When an Army Meteorological Service was established in 1915 it was a small unit which had to justify its existence, and in the course of exploring fields of usefulness it found the artillery ready and anxious for improved meteorological information. The shell from a high-velocity gun may rise to a height of 20,000 ft. or more, and surface conditions may be a very misleading guide. But to ask the gunner to use detailed observations of wind and of atmospheric pressure and temperature at different heights up to 20,000 ft. under active service conditions, and without previous training, was useless. The meteorologist, having found a sphere of usefulness, had to put his information in a form in which it could be used with the existing artillery organisation. It is already suggested in some quarters that the meteorological service adequately met the artillery's requirements during the war without any peace-time organisation, and that therefore it is unnecessary now to keep any close *liaison* between the gunner and the meteorologist. In the writer's view this is a great mistake. The meteorological service was able to help the gunner by doing work which the gunner could have done if he had received the proper training, and it is necessary that he should do this work for himself in order to make the best use for his particular gun of data supplied to him by the meteorologist.

The artillery organisation for meteorological corrections consisted in the supply to gunners of tables of variations in line and range produced by winds constant in velocity and direction at all heights and of variations in range produced by changes in surface temperature and pressure, based on the assumption that the ratio between the actual air density and that assumed in the construction of the range table was the same at all heights. It was a fairly obvious first step to suggest that the gunner should be supplied with a fictitious wind such that, when used with the usual table of variations, the proper correction was applied for the cumulative effect on the projectile before reaching the target of a wind varying with height. Such a wind came to be called the equivalent constant wind, or the ballistic wind, and methods of estimating it were investigated simultaneously by the Meteorological Section, R.E., and the Anti-Aircraft Experimental Section (A.A.E.S.) of the Munitions Inventions Department (M.I.D.). At first the investigations were entirely independent and from different points of view, but later they were continued in close cooperation under the sympathetic guidance of the Ordnance Committee.

An initial difficulty of great importance was that the ballistic wind is not the same for any two trajectories, even for the same wind distribution. But, fortunately, the height to which a projectile rises when fired on the flat is nearly the same for all projectiles which have the same time of flight, and also the length of time which such projectiles spend in any particular stratum of the atmosphere is nearly the same. Thus, though the range of a high-velocity gun may be double that of a howitzer for the same time of flight, yet the projectiles in each case rise to nearly the same height, and are affected by the same winds for nearly the same length of time. To a first approximation, therefore, the ballistic wind is the same for every projectile having the same time of flight, and if a selection of such winds for different times of flight is given to the gunner, he can choose the one most nearly suited to the conditions under which a shoot is taking place.

As a first approximation, in the calculation of the ballistic wind it was assumed that the atmosphere was stratified into several layers, and that in each layer the wind was constant in velocity and direction, though varying from layer to layer. It was further assumed that the effect of the wind in any layer on a projectile was proportional to the time spent by the projectile in that layer and to the density of the air. "Weighting factors" for the portion of the total displacement of the projectile caused by unit wind in any layer were thus determined. Subsequent mathematical analysis showed that the "weighting factors" varied materially for each different trajectory, and also differed for winds across and along the line of fire. Considerable refinements were introduced for the analysis of experimental shoots on which the construction of range tables was based. The researches of the A.A.E.S., M.I.D., though principally directed towards anti-aircraft gunnery, included careful and detailed discussions of variations in the trajectory of a shell produced by varying wind and density, and made the careful analysis of such experimental shoots possible. For a considerable period, however, the facilities afforded by the field meteorological service in the different theatres of war made possible much greater accuracy of correction than had been aimed at in the experimental shoots from which range tables were compiled. Ultimately average weighting factors, deduced from theoretical factors computed in a large number of cases, were adopted for different times of flight, and the method of constructing the ballistic wind for use in the field became standardised.

The second step was the introduction of the idea of ballistic density—a fictitious density such that when used with the usual tables of variations the proper correction is applied for the effect of an abnormal vertical distribution of density. Fortunately, the pressure and temperature which practically determine the air's density may be considered separately. If it is assumed that the vertical temperature distribution is known and remains unchanged while changes in pressure are registered at the surface of the earth, it is easily shown that there are proportional changes in pressure, and therefore in density, at all heights. Thus the surface barometer reading affords a real,

though partial, index of the density of the air at any height. From this the third step followed—the idea of a ballistic temperature such that when used in conjunction with surface pressure the ballistic density was arrived at. Methods of computing density weighting factors were developed by the A.A.E.S., M.I.D., and by using these factors temperature weighting factors were computed (which allowed for the variations in the vertical pressure distribution consequent on any variation in the temperature distribution). Here, again, the factors vary for each trajectory, but the differences between trajectories are considerably less than in the case of winds, and there was little difficulty in arriving at the best average factors to employ for field use.

By the employment of wind and temperature weighting factors, very numerous meteorological observations were made available for the use of gunners in the most convenient form. Ballistic winds and temperatures for several selected times of flight were telegraphed to the batteries at frequent intervals, and the information given in the meteorological telegrams, in conjunction with the barometric pressure measured at the battery, gave the gunner data which required no reduction, but could be used directly for applying corrections from the range table. It is, of course, essential that the results of meteorological observations should be provided "red hot" to the gunners, and methods of computation were so perfected, and so high a degree of skill was attained, that the calculation of ballistic winds from pilot-balloon observations kept pace with the observation of the balloon itself, and no time was lost in putting the information in the form in which it was readily usable by the gunner.

A single concrete example may suffice to illustrate the importance of the methods which were introduced by the meteorologists.

If a projectile were fired due south, with a time of flight of 50 sec. (*i.e.* rising to a height of about 10,000 ft.), under the following weather conditions, viz. :—

Height in ft.	Wind Velocity f.s.	Wind Direction °	Temperature ° F.	Barometer
Surface	8	110	50	
2,000	40	175	40	30·00 in. (Normal)
4,000	45	185	30	
6,000	50	190	19	
8,000	45	190	8	
10,000	60	185	−2	

Then, if surface conditions are used for arriving at the appropriate corrections to apply, we have for a certain gun that the wind will reduce the range of the gun by 13 yards and deflect the projectile towards the west 60 yards. The surface temperature being 10° F. below the range table normal of 60° F., the range will be further reduced by 42 yards—a total loss in range of 55 yards.

But the ballistic wind for the above conditions is a wind of 44 f.s. from direction 185°, and the ballistic temperature is 36° F. For the same gun and projectile this wind would produce a deflection towards the east of 35 yards, a decrease in range due to wind of 600 yards and to abnormal temperature (and density) of 407 yards—in all more than 1000 yards. Thus the corrections applied by pre-war methods would have entailed in this case an error in range of about 1000 yards, and in line of about 100 yards.

Instead of anti-aircraft gunnery being considered as a special department of gunnery, it is more logical to consider fire on the flat as a specially simple case of the more general science of gunnery. In a very real way the development of the science was due to the researches of the A.A.E.S., M.I.D., and to the methods employed by that department in the analysis of fuse trials and in the calibration of guns. For anti-aircraft fire under active service conditions the application of meteorological corrections did not reach the same degree of organisation as for fire on the flat, for the application of corrections is a much simpler problem in the latter case. But in experimental work full account was taken of all the meteorological information available. Thus one of the main sources of errors in shooting was eliminated, and the investigation of many ballistic problems made possible.

Obituary.

S. RAMANUJAN, F.R.S.

SRINIVASA RAMANUJAN, whose death was announced in NATURE of June 3, was born in 1888, in the neighbourhood of Madras, the son of poor parents, and a Brahmin by caste. I know very little of his early history or education, but he became a student in Madras University, and passed certain examinations, though he did not complete the course for a degree. Later he was employed by the Madras Port Trust as a clerk at a salary equivalent to about 25*l.* a year. By this time, however, reports of his unusual abilities had begun to spread, and, I believe owing to the intervention of Dr. G. T. Walker, he obtained a small scholarship which relieved him from the necessity of office work and set him free for research.

I first heard of Ramanujan in 1913. The first letter which he sent me was certainly the most remarkable that I have ever received. There was a short personal introduction written, as he told me later, by a friend. The body of the letter consisted of the enunciations of a hundred or more mathematical theorems. Some of the formulæ were familiar, and others seemed scarcely possible to believe. A few (concerning the distribution of primes) could be said to be definitely false. There were no proofs, and the explanations were often inadequate. In many cases, too, some curious specialisation of a constant or a parameter made

the real meaning of a formula difficult to grasp. It was natural enough that Ramanujan should feel a little hesitation in giving away his secrets to a mathematician of an alien race. Whatever reservations had to be made, one thing was obvious, that the writer was a mathematician of the highest quality, a man of altogether exceptional originality and power.

It seemed plain, too, that Ramanujan ought to come to England. There was no difficulty in securing the necessary funds, his own University and Trinity College, Cambridge, meeting an unusual situation with admirable generosity and imagination. The difficulties of caste and religion were more serious; but, owing to the enterprise of Prof. E. H. Neville, who happened fortunately to be lecturing in Madras in the winter of 1913–14, these difficulties were ultimately overcome, and Ramanujan arrived in England in April, 1914.

The experiment has ended in disaster, for after three years in England Ramanujan contracted the illness from which he never recovered. But for these three years it was a triumphant success. In a really comfortable position for the first time in his life, with complete leisure assured to him, and in contact with mathematicians of the modern school, Ramanujan developed rapidly. He published some twenty papers, which, even in wartime, attracted wide attention. In the spring of 1918 he became the first Indian fellow of the Royal Society, and in the autumn the first Indian fellow of Trinity. Madras University endowed him with a research studentship in addition, and early in 1919, still unwell, but apparently considerably better, he returned to India. It was difficult to get news from him, but I heard at intervals. He appeared to be working actively again, and I was quite unprepared for the news of his death.

Ramanujan's activities lay primarily in fields known only to a small minority even among pure mathematicians—the applications of elliptic functions to the theory of numbers, the theory of continued fractions, and perhaps above all the theory of partitions. His insight into formulæ was quite amazing, and altogether beyond anything I have met with in any European mathematician. It is perhaps useless to speculate as to his history had he been introduced to modern ideas and methods at sixteen instead of at twenty-six. It is not extravagant to suppose that he might have become the greatest mathematician of his time. What he did actually is wonderful enough. Twenty years hence, when the researches which his work has suggested have been completed, it will probably seem a good deal more wonderful than it does to-day.

G. H. HARDY.

PRINCIPAL SIR JOHN HERKLESS, D.D., LL.D.

SIR JOHN HERKLESS, whose death we regret to announce, was the son of an engineer in Glasgow; he was born on August 9, 1855, and educated in the High School before entering the University of his native city. His career as a student was varied, and his fellow-students did not think it outstanding. He not only studied arts, but also attended medical classes. Like some men who have afterwards made their mark in life, he disliked mathematics, but was fond of philosophy, and finally he decided to study for the Ministry, and was duly licensed, though he obtained no degree from his *Alma Mater*. For a short time he lectured on English literature at Queen Margaret College, then became an assistant-minister until 1883, when he was appointed to the parish of Tannadice in Forfarshire.

The death of the eloquent Principal Cunningham made a vacancy in St. Mary's College, St. Andrews, and it was rumoured that Dr. Herkless would be appointed to the post (divinity). Prof. Mitchell, however, resigned his chair of Church history, and he was appointed, whilst Prof. Stewart, of Aberdeen, was made principal. About this time the strained relations with Dundee in regard to the medical school, and the claims of St. Leonard's Parish in connection with the College Chapel, gave the forceful new professor of Church history an ample field for polemics. He took the side of Dundee, and opposed the parish. Besides stray papers, he afterwards published two books, viz. "Francis and Dominic" and "Richard Cameron," whilst, along with Mr. (now Prof.) R. K. Hannay, he edited a volume of documents pertaining to St. Leonard's College, and four volumes on the archbishops of St. Andrews. He was chairman of the St. Andrews School for Girls Company. He was appointed principal of the University by Mr. Asquith on the death of the distinguished educationist, Sir James Donaldson.

Though not a man of original cast of intellect, Sir John Herkless had great versatility and shrewdness, and was not devoid of ambition (as he himself stated), his main field for advancement being politics. He was diligent in his duties as principal, but he had little time to make noteworthy advances. His lamented death on June 11 occurred after an operation, and whilst he was in the midst of plans for the improvement of the University.

THE death of MR. CHARLES E. RHODES is announced in *Engineering* for June 11, and will be regretted by a large circle who knew him through his activity in colliery developments. Mr. Rhodes was born in 1849, and died on June 7 last. Since December, 1873, he held the position of engineering manager for Messrs. John Brown and Co., Ltd., for whom he sank several shafts and developed a number of pits. He became a member of the Institution of Civil Engineers in 1890, and at various times was president of different institutions connected with mining. He was appointed a member of the Standing Committee on Mining in 1916, and joined the Coal Conservation Committee in the same year.

WE regret to note that the death of MR. WILLIAM SHELDON is recorded in *Engineering* for June 11 as having occurred on May 20. Mr. Sheldon was in his sixty-ninth year, and had been connected with the steam plough works belonging to Messrs. Fowler since 1879. He was president of the Leeds Association of Engineers in 1898–99

Notes.

THE Linnean Society will be engaged to-day, June 17, in celebrating the centenary of Sir Joseph Banks, Bart., who died on June 19, 1820. On the death of Carl von Linné in 1778, Banks endeavoured to buy his herbarium, but that was acquired by Linné's son for the remainder of his short life. Five years later, when the herbarium was again for disposal upon the death of the younger Linné, Banks had changed his mind, for when the collections were offered he passed the offer to Dr. J. E. Smith, recommending the purchase, as it would be of great value to him as a young naturalist. On getting the herbarium Smith spent the winter of 1784–85 in collating his new acquisition with the Banksian collection, with the invaluable help of Jonas Dryander, Banks's factotum; then, after a tour abroad, Smith took counsel with his friends, and the Linnean Society came into being. Banks was chosen as honorary member immediately, and retained that position until his death. Besides continual gifts of books, the cast from Inlander's relief of Linné, which was the model for Wedgewood's plaque, and objects of natural history, he paid for the entire cost of illustration for the first volume of the Transactions. It is well that such liberal actions should be recalled to the memory of the present generation.

WE have received from the secretary of the Rubber Growers' Association particulars of a competition which has been organised by the association with the view of extending the industrial uses of rubber. A sum of 5000*l.* is offered for ideas and suggestions in this connection, the amount to be divided into the following awards, viz. one prize of 1000*l.*, three prizes of 500*l.* each, ten prizes of 100*l.* each, and a sum not exceeding 1500*l.* to be divided amongst the remaining competitors whose suggestions are considered to be practical, according to the relative value of the proposals. Among the conditions of the competition it is noted that special value will be attached to ideas of a thoroughly practical nature, supported by detailed information likely to make them effective; and that the relative value of the suggestions which are deemed practical will depend upon the quantity of raw rubber which their adoption would absorb, special consideration being given to proposals likely to utilise rubber in large quantities. The most important condition, however, is that relating to the protection by letters patent of any process, method, or apparatus submitted by competitors; this regulation is too long to quote in detail here. Full particulars of the competition may be obtained from the Rubber Growers' Association (Department C), 38 Eastcheap, E.C.3; the closing date of the competition is December 31 next.

THE Albert medal of the Royal Society of Arts for 1920 has been awarded to Prof. A. A. Michelson, For.Mem.R.S., professor of physics in the University of Chicago, and Nobel laureate for physics in 1907.

THE enterprise of the Royal Horticultural Society in holding a three-days' show at Cardiff on July 6–8 marks a new departure in the society's history. Not in the present generation has it held such a meeting in the provinces, and it has now taken this step to foster the interest in gardening and the production of home-grown produce that it did so much to develop during the war period. The scientific section will contain exhibits showing how to identify and overcome the various garden pests, as well as displays of the various appliances used in repelling their attacks.

THE David Syme prize, with medal, for the year 1920 has been awarded to Mr. Frederick Chapman, palæontologist to the National Museum and lecturer in palæontology in the University of Melbourne. Mr. Chapman, before his first appointment in Australia, was known to a wide circle in London through his work under Prof. Judd and his association with Prof. T. Rupert Jones in the investigation of fossil Foraminifera. Foraminifera have always remained his special object of research, but he has published a large number of papers in all branches of palæontology, including a revision of the fossil fish-remains of New Zealand. Few men have rendered the results of their observations available with such zeal and regularity, and Mr. Chapman, from the date of his earliest papers, when he described the preparation of thin sections of minute objects for the microscope, has brought to his painstaking studies the enjoyment of an artist in his work.

AT the anniversary meeting of the Linnean Society on May 27, the following officers and members of council were elected:—*President:* Dr. A. Smith Woodward. *Treasurer:* Mr. H. W. Monckton. *Secretaries:* Dr. B. Daydon Jackson, Prof. E. S. Goodrich, and Dr. A. B. Rendle. *Council:* Mr. E. G. Baker, Mr. H. Bury, Prof. Margaret Benson, Mr. E. T. Browne, Mr. Stanley Edwards, Prof. J. B. Farmer, Prof. E. S. Goodrich, Capt. A. W. Hill, Dr. B. Daydon Jackson, Mr. C. C. Lacaita, Mr. G. W. E. Loder, Mr. H. W. Monckton, Mr. R. I. Pocock, Dr. A. B. Rendle, the Rt. Hon. Lionel Walter, Baron Rothschild, Dr. E. J. Salisbury, Mr. C. E. Salmon, Miss A. Lorrain Smith, Lt.-Col. J. H. Tull Walsh, and Dr. A. Smith Woodward. The president has appointed Mr. E. T. Browne, Prof. J. B. Farmer, Mr. H. W. Monckton, and Mr. R. I. Pocock vice-presidents. Dame Helen Gwynne-Vaughan was presented at the anniversary meeting with the Trail award and medal, and Sir Ray Lankester with the Linnean medal.

A SUCCESSFUL meeting of the British Lampblown Scientific Glassware Manufacturers' Association, Ltd., was held on June 8 at the Abercorn Rooms, Great Eastern Hotel. Mr. Douglas Baird, vice-president of the association, who occupied the chair, in proposing the toast of "The B.L.S.G.M.A.," gave a short history of the formation of the association. The manufacturers who were members of the association were engaged in work which could be truly designated a "master-key industry," because there was no trade or profession that could be successfully carried on without the aid of one or other of the instruments manufactured by its members. The association was formed during the war because it was found by the Government that there was a great demand for all kinds of instruments for the fighting forces which previous to hostilities had been introduced into this country from abroad,

and more particularly from Germany. The Government experienced great difficulty in getting in touch with manufacturers, and it was at the suggestion of the Ministry of Munitions that the B.L.S.G.M.A. was formed. Mr. Baird emphasised the necessity of each member in the association uniting to their utmost in promoting and fostering the industry. He pointed out that it was only by united effort to turn out instruments of the highest class of manufacture that the country could hope to keep out the importation of foreign glassware.

SIR C. H. READ, in his presidential address delivered before the Society of Antiquaries, does not take an optimistic view of the prospects of archæological research. While the late German Government lavished treasures on the Berlin museums, the British Museum, our one institution archæological in its aims, is hampered by lack of funds. Again, the regulations against the export of specimens from countries under our control have proved to be ineffective. For example, specimens found in Cyprus are smuggled to any other art centre rather than to London, and the silver treasures from that island passed easily into the Pierpont Morgan galleries in New York. The same result of Government action is anticipated in India. The president is, however, scarcely fair in his strictures on the Indian Government. Why, he asks, are the Indian museums filled with statuary of the Buddhist age?—things which he believes are hated by Mussulmans and almost equally disliked by Hindus. He forgets that many of the Indian Mussulmans, being converts from Hinduism, have in a measure lost that hatred for representations of the human form which survives in orthodox cities like Cairo. Hindus have recognised Buddha as an incarnation of Vishnu, and the ignorant Hindu villager often worships a figure of the Master as a representation of some local deity, male or even female. But Sir Hercules Read is well justified in pleading for the development of excavation in Babylonia and in Egypt, in which latter country Prof. Flinders Petrie has done admirable work with very limited resources. He also wisely lays stress on the fact that, while our galleries abound in examples of art in its highest forms, we have comparatively little to illustrate the everyday social life of the populations which are now subject to our control.

THE tenth International Cotton Congress was held in Zurich on June 9–11. In the course of its proceedings a highly suggestive paper was read by Dr. W. Lawrence Balls, scientific expert and adviser to the Fine Cotton Spinners' Association, Ltd., Manchester, on "The Nature, Scope, and Difficulties of Research," in which he dealt with the foundation of research, the past and present scope of the research on cotton, the British organisation of cotton researches, and international research. The demand for scientific research, with the view of enlarging the possibilities of the industry, embracing not only the cultivation of the plant, but also every subsequent process in its utilisation, has been induced by various changes in recent years. There is a vast accumulation of experience in the cotton industry, together with a small stock-in-trade of general knowledge. Most of the work of the first decade undertaken by the scientific workers will have to be spent in defining what the spinner knows, and then in reducing the incoherent mass of details to a small number of generalisations easy to grasp. The question of the method of utilisation of the results of research which may be condensed under the title of publication is summed up in a line: To ascertain the true facts, to conceal nothing known, and to take personal responsibility. There must be individualism in effort and communism in knowledge, which is put forward as the code of the pure scientific worker. With respect to a code of research for industry, the author insists on the need for individual effort, but also that after five years the industrial research worker and his employer-colleague shall make known the true facts ascertained, which, whilst giving full advantage to the business concerned, shall yet give fair and full assistance to the general advance of man's power over his environment.

IN *Man* for May Mrs. M. E. Cunnington describes a curious stone mould found on the Worms' Head, Glamorganshire. It is made of two pieces of fine-grained red sandstone about an inch thick. On the corresponding sides of the two stones are matrices for casting four objects: a large ring ornamented with a raised pattern of S-like scrolls enclosed by two narrow rows of irregular chevrons or waved lines, a ring with seven star-like rays, a second ring, and another smaller with a raised pattern of waved lines or loops with seven points. It is suggested that this ornamentation has been designed with some reference to sun-worship, the disc, the rayed star, and the S scrolls being all well-known solar symbols derived from the wheel. From the objects found in association with these moulds it may be inferred that they belong to the Early Iron age. This part of the coast, though difficult of access by land, was easily reached by sea from other parts of Britain and from the Continent. The moulds may thus possibly have been introduced from abroad.

THE Oxford University Press has issued a revised edition of its General Catalogue, which was first produced in 1916. It is not only an excellent description of the varied activities of this great publishing institution, but it is also valuable as a fine example of scientific bibliography, and forms very interesting reading. The Press offers this valuable service to science and literature that the profits derived from school books and other more or less popular works are devoted to the publication of expensive volumes of permanent value which the ordinary publisher may hesitate to produce. One book, Woide's Coptic New Testament, published in 1799, is still on sale. There is an account of the "Dictionary of National Biography," the copyright of which was presented to the University by the family of its founder, the late George M. Smith. Preliminary work under the direction of Mr. H. W. Carless Davis is now in progress with the view of maintaining and extending its usefulness. A history, of course, is given of what is now called the "Oxford Dictionary," which since the

death of Sir John Murray in 1915 has been controlled by Dr. H. Bradley and Messrs. W. A. Craigie and C. T. Onions. Nine of the ten volumes are complete, and as steady progress in the tenth volume is being made we may soon look forward to the completion of this monumental work.

IN the Annual Report of the Director of the Field Museum of Natural History, Chicago, for 1919, perhaps the most novel pages are those dealing with the work of the botanical laboratories established by Mrs. Stanley Field. Their main object is to make reproductions of living plants for exhibition in the museum. To accomplish this the plants are studied in the field, wherever they are best to be seen. Thus the first four and a half months of the year were spent in Florida, at a station of the U.S. Department of Agriculture, to secure studies and material for such plants as the coconut palm, the banana, the pineapple, and the Florida cycad. The most perishable parts were cast and coloured, and plaster moulds were made of other parts, formalin material packed and sent to the museum, and photographs, colour sketches, and detail studies secured for use after return. Reproductions were made of many other plants cultivated in the garden of the station. A set of tomatoes attacked by various fungi, then under investigation at the station, was reproduced, and pure cultures of the fungi were obtained with the view of making an enlarged model of each fungus for exhibition alongside the infected fruit.

FEW works of the same size have had so wide an influence on geological thought as R. Liesegang's "Geologische Diffusionen," published in 1913. Applications of the author's views on zonal deposition are to be found, with excellent illustrations, in Professional Papers 107 (p. 156) and 104 (p. 45) of the U.S. Geological Survey. In the former case banded jasper-rock is considered; in the latter, the very common occurrence of bands of iron hydroxide. Messrs. Bastin and Laney, in Paper 104, have made useful experiments with interfusing solutions of ferrous sulphate and sodium hydroxide.

A COLOURED geological map of Western Australia, called a sketch-map, but none the less valuable to libraries, accompanies the Annual Progress Report of the Geological Survey of that State for 1918 (published 1919). Its scale, 1 in. to 50 miles, or about 1 : 3,000,000, is large enough to enable us to appreciate the immense extent of Nullagine (Late Pre-Cambrian?) beds in the north-west, with their auriferous conglomerates; the Jurassic fringe on the west coast; and the Cretaceous overflow on Palæozoic strata in the south-east. An interesting case of serviceable limestone formed by capillary action in sand-dunes is described on p. 14 of the report.

A SUMMARY of the weather for the spring season, comprised by the thirteen weeks ending May 29, is given in the *Weekly Weather Report* issued by the Meteorological Office. Mean air temperature for the period was above the average in all districts of the British Isles, the largest excess being 3·2° F. in England E. and 2·9° F. in England S.E. In Ireland the excess was not more than ½° F., and in Scotland it was only about 1°. At the close of the season the sheltered thermometer exceeded 80° F. in most of the English districts. The day-degrees above 42° F. were largely in excess of the normal over the whole kingdom, especially in England E. and in the English Channel, whilst the day-degrees below 42° F. were largely deficient everywhere, especially in the Midland Counties and in England E. and N.E. Rainfall was everywhere in excess of the normal, the greatest excess being 5·67 in. in England N.W. In the English Channel the excess was only 0·59 in., and in England S.E. and E. 0·63 in. and 0·67 in. respectively. The duration of bright sunshine was normal in Scotland N., but deficient in all other parts of the British Isles. In Scotland W. the deficiency was 109 hours, and in England N.W. and Ireland S. 91 hours.

THE second part of the current volume of the Proceedings of the Royal Irish Academy consists of a paper by the late Prof. J. A. McClelland and Mr. A. Gilmour on the electric charge on rain. The observations were made in a small quadrangle at the back of University College, Dublin, between January 1 and August 31 last year. The results for non-thunderstorm rain are that 73 per cent. of it was charged positively, and 84 per cent. of the electricity brought down was positive. The average charges brought down by the rain were 0·21 electrostatic unit positive and 0·08 negative per c.c. of water. The average vertical currents were $1{\cdot}6\times10^{-15}$ amperes per sq. cm. positive and $0{\cdot}5\times10^{-15}$ negative. Drops below $0{\cdot}08\times10^{-3}$ c.c. were always negatively charged, but there appeared to be no relation between the size of the drop and the magnitude of its charge. Thunderstorm rain was more highly charged than ordinary rain and about equally positive and negative. Snow was more often negative than positive, small hail always negative, and large hail always positive, the charges per c.c. exceeding those on ordinary rain and often those on thunderstorm rain.

IN Publication No. 298 of the Carnegie Institution of Washington (1919) Messrs. E. L. Nichols and H. L. Howes, with the collaboration of Messrs. E. Merritt and D. T. Wilber and Miss F. G. Wick, give the results of a very exhaustive investigation of the fluorescence and absorption spectra of uranyl salts. The authors have examined a large number of simple and double salts, the influence of water of crystallisation and of crystalline form, and the polarised fluorescence of crystals at ordinary temperatures and at the temperature of liquid air. The results obtained at low temperatures are of particular interest, for under these conditions both the absorption and fluorescence bands, which at ordinary temperatures are so diffuse that it is difficult even to locate the positions of the maxima with great precision, are resolved into a number of comparatively sharp components the homologous members of which can be arranged in series having constant wave-number

differences. The authors arrive at the generalisation that resolution of the bands on cooling depends on the existence of regular crystalline structure; as an example of this, the broad bands observed in uranium glass are not further resolved on cooling to the temperature of liquid air. It is shown that many of the apparent shifts of the bands with change of temperature are to be referred to the relative enhancement or diminution of the components of the bands. A discussion of different types of phosphoroscope is included as an appendix.

THE May lecture of the Institute of Metals on "Recent Progress in Thermo-Electricity" was delivered by Prof. C. A. F. Benedicks, of Stockholm University, on June 10, Engineer Vice-Admiral Sir George Goodwin, president, in the chair. Prof. Benedicks first gave a short summary of his theoretical views upon the metallic conduction of electricity. A consequence of this theory was that one has to conclude that even in a single homogeneous metal thermo-electric currents do occur, and not only when two different metals are present. Prof. Benedicks gave a concise demonstration of the most important experimental evidence of the truth of this conclusion, utilising for this purpose various metals. In liquid mercury it had been possible for him definitely to prove the existence of thermo-electric currents, thus disproving the negative results of previous workers. A consequence of what the lecturer termed his "homogeneous *thermo-electric* effect" was that there must exist the *reverse* effect, the "homogeneous *electro-thermic* effect," including as a special case the well-known Thomson effect. The reality of this effect was duly made clear. A specially interesting demonstration was of a new rotating thermo-electric apparatus made entirely of copper and rotating in a magnetic field, the driving force originating solely from unequal heating (by means of a tiny gas jet) of thin strips of copper. The point at which the new knowledge brought forward by Prof. Benedicks might have some practical interest lay in the possibility of reducing the thermal conductivity of metals by insulated subdivision into fine wires without impairing the electrical conductivity. The demonstrations were carried out with the aid of a galvanometer kindly provided by the Cambridge and Paul Instrument Co.

DRS. A. HARDEN AND S. S. ZILVA, continuing their work on accessory food substances, publish in the *Biochemical Journal* for April a paper entitled "The Antiscorbutic Requirements of the Monkey." The authors point out that as the clinical symptoms of scurvy induced in the monkey are similar to those occurring in human subjects suffering from a similar disease, the monkey has been more and more extensively employed as an experimental animal. On the other hand, comparative scarcity, high price, and greater duration of experiment render the monkey in many instances less suitable than the guinea-pig for the study of experimental scurvy. In order to translate results obtained with one animal into the terms of the other Drs. Harden and Zilva have attempted to establish a quantitative relationship, as regards dose and time, between them. In the work described five monkeys fed on a scorbutic diet of rice, wheat germ, salt mixture, and butter received respectively 0·5 c.c., 0·75 c.c., 1 c.c., 2 c.c., and 5 c.c. respectively of orange juice daily. The animals receiving only 0·5 c.c. or 0·75 c.c. developed scurvy with fatal results, whilst the one receiving 1 c.c. only suffered from a mild attack, and in the cases of 2 c.c. and 5 c.c. doses the animals remained quite healthy. The authors conclude that the minimum daily dose of fresh orange juice for a monkey (weighing 2–3 kilos.) is 1–2 c.c., which is approximately the amount required by a guinea-pig weighing 300–400 grams. Whilst, however, the minimum dose of antiscorbutic required by the two animals is of the same order, the disease develops in the guinea-pig in three weeks, but only after two months in the monkey.

IN pursuance of his campaign for recognition as a pioneer inventor of oil engine cycles, we have received a number of documents from Mr. Herbert Akroyd Stuart, formerly an assistant at Finsbury Technical College and now of Claremont, in Western Australia. One type of Mr. Stuart's engines has been manufactured on a large scale by Messrs. Hornsby, of Grantham. The cycle in this engine is carried out in a cylinder fitted with a hot bulb, the walls of which are kept hot during ordinary working by the heat developed during explosion. Air is drawn into the cylinder through a side-port in front of the bulb, and oil fuel injected into the bulb during the suction stroke. Compression follows, and at the end of this stroke ignition takes place due to the temperature developed by the hot walls and by the compression. Mr. Stuart's other cycle has not been worked commercially to any extent. It also is carried out in a hot-bulb cylinder, and consists in drawing in air only during the suction stroke, compression of this air, and injection of oil fuel into the bulb during the early part of the working stroke, the temperature being then sufficient to cause the oil to burn readily. Both these cycles were invented in 1890. Mr. Stuart objects, and rightly so, to the name "semi-Diesel" being applied to engines working on these cycles. He has first claim as the inventor of hot-bulb engines, and the term "Akroyd cycle" would be suitable. The Diesel engine proper has no hot bulb; air alone is compressed to a very high pressure (500 lb. per sq. in.), and the temperature due to compression alone is sufficient to ignite the oil fuel which is injected during the early part of the working stroke. The term "Diesel engine" might continue to be used for such engines. The high pressures used in the Diesel engine and the extensive use of the engine for marine purposes gave rise to a demand for an engine working with lower pressures, and the past few years have seen a great development in hot-bulb engines. Someone acquainted with Diesel engines and probably unaware of Mr. Stuart's prior work named these "semi-Diesel," a term which may very well be dropped in favour of Akroyd engines, if only for the sake of historical accuracy.

Our Astronomical Column.

THE MASSES OF THE STARS.—The mass of a star is perhaps its most important element, but it is one that can be ascertained only in exceptional cases. Prof. H. N. Russell, in a paper read at the twenty-first meeting of the American Astronomical Society, gathered together all the evidence, direct and indirect, on the subject, grouping the results by spectral type. Method I. is the usual one for visual binaries the orbits and parallaxes of which are known; Method II. is similar, where the parallax and relative motion, but not the orbit, are known; Method III. is from spectroscopic binaries where both spectra are shown, a mean inclination being assumed; and Method IV., the vaguest of all, derives the parallaxes of binaries from their proper motions.

The resulting mean masses for the pairs of stars are:—

Spectrum		I.	II.	III.	IV.
B_0–B_5	... ...	—	10·4	17·5	7·1
B_8–A_5	... ...	5·9	3·0	4·0	8·4
F–G	giant	—	—	3·9	8·1
K–M	giant	—	—	—	9·8
F–F_5	dwarf	3·5	3·4	—	2·5
F_8–K_0	dwarf	1·8	1·4	—	0·7
K_5–M	dwarf	0·7	1·0	—	—

The sun's mass is taken as 1.

The following formulæ are given for the hypothetical parallax (h) of systems of mean distance a, and period P: $h=f\frac{a^3}{P^2}$; or where s is the apparent distance and w the apparent relative motion, in seconds of arc per annum, $h=0{\cdot}409 f s^{\frac{1}{3}} w^{\frac{2}{3}}$.

The constant f has the value 0·50 for all giant stars, 0·58 for dwarfs of spectrum A, 0·72 spectrum F, 0·86 spectrum G, 1·00 spectrum K, and 1·14 spectrum M. The probable error is given as 12 per cent. where the first formula can be used, and as 22 per cent. in other cases.

THE PLANET JUPITER.—The Rev. T. E. R. Phillips, director of the Jupiter section of the British Astronomical Association, contributes an interesting article on the planet to the June number of *Scientia*. After giving a *résumé* of Jovian phenomena during the last twenty years, including the red spot and the south tropical disturbance, Mr. Phillips notes the startling change in the aspect of the planet which took place early in 1919; the disturbance and the red-spot hollow both practically disappeared, though the spot itself survived. Discussing the physical condition of Jupiter, he notes the similarity to the sun in density, in varying rotation periods according to latitude, and in the dark belts which are comparable with the spot zones. He suggests that the red spot may indicate a vast cyclonic movement in the atmosphere, noting that this view would explain the rapid passage of the dark matter of the tropical disturbance round the spot when the two are in conjunction. He notes, in conclusion, the importance of Jovian study from the point of view of cosmogony, since it illustrates a stage intermediate between the solar condition and the earliest geological periods.

PARALLAX WORK AT THE SPROUL OBSERVATORY.—The list of stars with known parallaxes is being rapidly extended, thanks to the extensive organised campaign carried on by many observatories which possess large equatorials. Dr. Miller, of the Sproul Observatory, has published a useful list of fifty observed parallaxes (Proc. Amer. Phil. Soc., vol. lix., No. 2). Five stars on the list have parallaxes above 0·1″, viz. W.B. (1) V. 592=0·146″, 9 Argus=0·121″, *i* Persei=0·120″, Lalande 17161=0·104″, and W.B. (1) IV. 1189+0·103″. The values found for γ^1 and γ^2 Andromedæ are 0·021″ and 0·005″; those for the preceding and following components of the wide pair 16 Cygni are +0·037″ and +0·018″. In each of these systems the true parallaxes of the components are presumably the same. The discordances are a measure of the probable errors, which in each case are of the order of 0·01″.

An interesting feature is the closeness with which the new figures verify many of Prof. H. N. Russell's hypothetical parallaxes, deduced from assumptions regarding the masses of binaries.

Nuclear Constitution of Atoms.[1]

By SIR ERNEST RUTHERFORD, F.R.S.

THE idea of the nuclear constitution of atoms was developed from an examination of the scattering of swift α-particles in passing through matter, and the advance afterwards made was due to the proof by Moseley of the close connection between the atomic number of an element and the nuclear charge. The accurate determination of the nuclear charge is of prime importance. Recent unpublished experiments by Mr. Chadwick in the Cavendish Laboratory indicate that the nuclear charge on an atom in fundamental units is equal to the atomic number within an accuracy of about 1 per cent. It follows that there is a region surrounding the nucleus where the law of the inverse square holds accurately. The problem of the constitution of the atom divides itself naturally into two parts: one the arrangement of the external electrons on which the ordinary chemical and physical properties of the atom depend, and the other the constitution of the nucleus on which depend the mass of the element, the possibility of isotopes, and radio-activity. The nucleus is composed of positively charged units and negative electrons in very close combination, and estimates of its dimensions are possible from a study of the collision of α-particles with light atoms. Close to the nucleus there is a rapid change in the magnitude and direction of the forces, probably in part connected with the deformation of the nucleus structure under the intense forces which arise in a close collision.

Unless the nuclei are very stable, it is to be anticipated that they would be deformed, and possibly broken up, as a result of a direct collision with swift α-particles. In previous experiments evidence was given that long-range particles resembling hydrogen atoms were liberated by the passage of α-particles through pure nitrogen. New experiments have been made to determine by a modified method the nature of these particles by bending them in a magnetic field. The amount of deflection of the particles liberated from the nitrogen of the air was shown to be the same as for H atoms arising from a mixture of hydrogen and carbon dioxide. This showed definitely that hydrogen is one of the products of the disintegration of the nitrogen atom, and is one of the original components of the nitrogen nucleus. The possibility that the long-range particles are atoms of mass 2, 3, or 4 carrying a single charge may be definitely excluded.

The deflection in a magnetic field of the short-range particles which are liberated from nitrogen and oxygen, and were originally assumed to be recoil atoms of these elements, is not only much greater than that to be expected for such recoil atoms, but is also greater than the α-particle but less than the H atoms liberated from a mixture of hydrogen and carbon dioxide.

[1] Synopsis of the Bakerian Lecture delivered before the Royal Society on June 3.

There is evidence that these particles are atoms of mass about 3, carrying two charges. Consequently the atom of nitrogen can be disintegrated in two ways by collision with α-particles: one by the escape of an H atom, and the other by the expulsion of mass 3, and both processes occur independently. Atoms of mass 3 are also released from oxygen atoms, but H atoms cannot be detected.

It may be concluded, therefore, that atoms of mass 3, carrying two positive charges, are components of the nuclei of nitrogen and oxygen.

This new atom is to be regarded as an isotope of helium, and should give nearly the same spectrum. The energy of motion of the atom of mass 3 expelled from nitrogen and oxygen is about 8 per cent. greater than the original energy of the α-particle, showing that energy is liberated as a result of the disintegration. The atoms of mass 3 probably consist of three hydrogen nuclei with one binding electron, and atoms of helium of four hydrogen nuclei and two electrons. Apart from hydrogen itself, these atoms are important secondary units in the building up of atomic nuclei. In the light of the new experimental evidence, examples are given of the possible modes of formation of isotopes and possible structures of nitrogen and oxygen nuclei are considered. It is pointed out that close combinations may exist of H nuclei and electrons, giving rise to atoms of zero nuclear charge, and that such a conception is needed to explain the evolution of the heavy elements.

The Rockefeller Gift to Medical Science.

As was announced in the *Daily Mail* of June 11, the Rockefeller Foundation for Medical Research has made the generous gift of a sum of 1,205,000*l.* for the advancement of teaching and research in the Medical School of University College and Hospital. Owing to the inconsiderate and premature manner in which the statement was made public, it is natural that some mistakes should have been made and the objects of the gift in certain respects misunderstood.

The reason for the delay in making a public announcement is that the Senate of the University of London has as yet had no opportunity of formally accepting the gift. When this had been done it was the intention to make it public through appropriate channels and in such a way that the people of England might appreciate the intention of the donors to give a manifest proof of the friendliness of their feelings towards the work that we are doing here and their appreciation of its value. We have reason to believe that they particularly wish this aspect to be emphasised. It should be remembered that the object of the Rockefeller Foundation is "the welfare of mankind," so that its benefits were not intended to be confined to the United States. The members of the Foundation desire it to be regarded as entrusted to them for this purpose, and the present endowment is not meant in any way as a charitable gift. In view of statements to the contrary, it is necessary to make it plain that no conditions are attached, and that the recipients are left free in a very wide sense to make the best use of the money for the benefit of medical science, and especially as to the details of its application. It will naturally be understood that the manner of its use has been the subject of much discussion between representatives of the Rockefeller Foundation and the institutions receiving the gift.

With regard to the objects to which it is proposed to devote the endowment, a few words on the history of the negotiations may be of interest. Towards the end of last year two representatives of the Rockefeller Foundation, Dr. Wickliffe Rose (General Director of the International Health Board) and Dr. Pearce (Adviser in Medical Education to the Foundation), arrived in London. Before proceeding further they called at University College. In the absence of Prof. Starling, they were received by the present writer, whom they gave to understand that they had come to make inquiries into the conditions of medical education in London. They were accordingly informed of the recent creation of medical and surgical "units," of their situations and the names of various gentlemen associated with these units from whom they might obtain further information. This they proceeded to do. Early in the present year they made another visit to University College with definite proposals, and were seen by Prof. Starling and Prof. Elliot Smith, who showed them what was necessary to be done for the adequate provision of instruction and research in the fundamental sciences of anatomy, physiology, and pharmacology. It was clear to them that the most pressing need was the building of a new anatomical institute, although the medical sciences themselves naturally required the larger proportion of any proposed gift.

In April four representatives of University College and Medical School visited the United States for the purpose of further conference. These were the Provost (Sir Gregory Foster), Dr. Blacker (Dean of the Medical School), Prof. T. R. Elliott (professor of medicine), and Prof. Elliot Smith (professor of anatomy). On their return they brought back the definite offer of this extremely generous gift, and speak with the greatest appreciation of the friendliness of the manner in which they were received, the spirit in which the offer was made, and in which it was impressed upon them that it should be accepted.

Owing to the premature publication of the scheme it was necessary to call a general college meeting on Friday last, at which the Provost made a statement of its actual terms. In the words of the Rockefeller Executive Committee, they are as follows: "(1) An institute of anatomy. (2) Increase of clinical facilities. (3) Clinical laboratories planned. (4) Increased maintenance costs. (5) Closely unified administration." The Medical School will receive 835,000*l.* and the College 370,000*l.* Further details of the ways in which it is proposed to utilise the money will be duly announced. At this meeting Prof. Elliot Smith pointed out that anatomy is to be understood as including in its purview the microscopic structure of the tissues, embryology, and a study of the factors governing the development of form. It is further to be hoped that the working of the scheme will involve a much closer co-operation between the College and the medical departments, to the advantage of both.

It is perhaps advisable to direct attention to the fact that the gift is for the purpose of improving medical education and research. At the same time the hospital, as an institution for the cure of patients, will benefit indirectly, although doubtless its working expenses will be increased owing to the enlargement proposed.

W. M. BAYLISS.

The Permanent Value of University Benefactions.

An account of the opening of the new building of the Department of Applied Statistics and Eugenics at University College, London, presented by Sir Herbert Bartlett, was given in last week's NATURE. The speech made by Prof. Karl Pearson in seconding the vote of thanks to the donor contains certain truths which have a wider application than to the immediate audience, and we therefore reproduce it

in the hope that it will help to force the present difficult situation of the universities upon the attention of the public.

Henry VI., 1422–61. You probably all think of him as a weakling, the monarch whose forces were cleared out of the best part of France by Joan of Arc—a man naturally almost imbecile, and dominated by his Queen and a succession of dukes, and finally deposed by the victorious House of York. I feel otherwise towards him. For forty-five years I have worked under his image in a niche of my library. On my rare visits to Cambridge I would raise my hat to his statue on the front lawn of the college he founded. He may have been a poor King, but I owe the six most useful years of my life to the freedom his benefaction gave me to travel and to study. Despised as a King, there are many of us who respect our Royal benefactor as a scholar and a gentleman.

The spirit in which the members of old Cambridge colleges regard their founders and benefactors is one that should take deeper root in our new universities.

It is not merely the recognition of the name, but the insight that shall appreciate what the benefactor desired us to achieve, and the determination of successive generations that the purpose of the benefaction shall be carried out.

There are only too many ways of disposing of money! In 1441 it might be done by wars in France, by endowing monasteries to expedite the passage of your soul through purgatory, but those who founded or extended great centres of learning have remained in men's affection for all time. Nowadays you can dispose of your money to party funds or to charities; your name will survive just as long as your money is unspent or you have more to give. But the man who gives generously to a great academic institute will, if he chooses wisely, be certain of an ever-green memory.

In this institute we have had a number of benefactors, but three stand out for special mention on such an occasion as the present. The Worshipful Company of Drapers, who from 1903 onwards have assisted one section of our enterprise. Sir Francis Galton, who came of a family which has founded no fewer than three academic chairs, the Sedleian, the Savilian, and my own chair. Under his inspiration we work, and we are more than pleased to be better able to keep his memory fresh in our new buildings here than has been possible in the past in our cramped and temporary homes.

Lastly, we come to the benefactor whose benefaction is the subject of our gathering to-day. To him not only I, but every member of my staff feel daily gratitude for providing us with a more fitting, and, I will add, a more healthy environment, than we ever imagined would be ours, and I trust that the tradition will remain long after I have ceased to share the comfort of this building and the possibilities for the studious life it provides.

Those who have gone round this laboratory will have noted that we try to keep before us not only the portraits of great leaders of thought, but the portraits of the men who have made our work possible, and in this respect I should hope to be pardoned if I reminded Sir Herbert Bartlett of how deeply we should all appreciate the addition of such a memorial of his gift, so that we may have his form as well as his good works before us.

The war has left all academic enterprise stranded. In 1914 we could have equipped and fitted this building from basement to top story. Our contracts were rescinded, and for five years this laboratory was used as a military hospital. At present the fine buildings Sir Herbert Bartlett has provided lie to a large extent unoccupied. In 1871 the German nation made the extension of old and the founding of new universities a first claim on their war indemnities. In 1920 we hear no suggestion that from our universities a new national life has to spring, and that if they are to accomplish their task it can only be if the State and private friends come to their help in the present critical state of affairs. In this respect we can only trust that others will be as wise both for the present and for the future as Sir Herbert Bartlett has been. The winning of the war has been attributed in succession to many causes. One factor is rarely referred to, namely, the unselfish way in which the academic staff of university after university gave up their academic repose, broke through all their scholarly studies and their scientific researches, and, where they could not sacrifice their lives, at least sacrificed many of their best years of work for national service. Voluntary, and unpaid, and unpayable gifts for national welfare! It is absurd that the universities should have to prate of such labours; but here is the fact, regard it in what aspect you like, that with a greater task than ever before them, they are left with far less power to carry it out than they had before the war, and it is that knowledge which makes us the more deeply grateful to the special benefactor whom we wish to honour in this vote of thanks. He saw our necessity and responded to it.

The Imperial Entomological Conference.

THE Committee of the Imperial Bureau of Entomology may be congratulated on the success of the Entomological Conference which met on June 1–11 in the Linnean Society's rooms, Burlington House, London. The conference was attended by twenty official delegates representing most of the British Dominions, Colonies, and Protectorates, as well as by members of the committee of the Bureau, while a number of entomologists were invited to the meetings and discussions which occupied most of the appointed days. At the opening of the conference the delegates were received by Viscount Harcourt, chairman of the committee, and business meetings were held on the first and final days. On Friday, June 4, the conference visited the Rothamsted Agricultural Experiment Station in conjunction with a meeting of the Association of Economic Biologists; an account of this interesting day appeared in last week's NATURE (p. 464). On Tuesday, June 8, the members journeyed to Oxford, and on Thursday, June 10, to Cambridge. Prof. E. B. Poulton acted as host on the former, and Sir Arthur Shipley on the latter occasion. While the entomological collections in the University museums were the chief objects of interest, time was found for brief inspection of some features of the historic cities; for example, after entertaining the conference to lunch in Christ's College, Sir Arthur Shipley took the Overseas delegates into the rooms occupied ninety years ago by Charles Darwin.

Of the meetings held on the other five days of the conference it may be said that several subjects of much importance and of general interest were well and earnestly discussed. On the morning of June 2, under the presidency of Dr. R. Stewart MacDougall (Edinburgh), Mr. C. P. Lounsbury (Entomologist to the Union of South Africa) spoke on "Legislation in Regard to Plant Pests in the British Empire," insisting that the official entomologist should have authority to draft and enforce regulations against the introduction of plants which might harbour harmful insects; he advocated the drastic exclusion of such plants except in certain special cases, and expressed the opinion that little or no reliance can be placed on

certificates of freedom from pests—a view afterwards supported by several others who took part in the discussion. Mr. H. J. Elwes, however, remarked that a long experience in cultivation had convinced him that needless interference with freedom of import had sometimes been exercised by the authorities. On the chairman's suggestion, a sub-committee was appointed to consider the establishment of an Empire Convention on the subject.

"The Education of Economic Entomologists," the subject for discussion at the next morning meeting presided over by Prof. Poulton, was introduced by Prof. H. Maxwell Lefroy (Imperial College of Science). Prof. Lefroy advocated the establishment of entomology as a subject independent of general zoology, and, describing the courses in his own college, emphasised the necessity of a broad scientific training in physics, chemistry, and biology before the specialised entomological work could be profitably taken up; men with exceptional aptitude, however, might be admitted direct to advanced entomological study. The discussion was continued by Dr. R. J. Tillyard (Nelson, N.Z.), Dr. R. Stewart MacDougall (Edinburgh), Mr. F. Balfour Browne (Cambridge), Prof. R. Newstead (Liverpool), Prof. G. H. Carpenter (Royal College of Science, Dublin), Prof. R. D. Watt (Sydney, N.S.W.), and Mr. F. V. Theobald (Wye). While some doubt was expressed as to the advisability of divorcing entomology from general zoological study, there was general agreement as to the need of a sound and comprehensive scientific training, and several of the speakers insisted further that all entomologists in direct contact with cultivators ought to have practical knowledge of farm or garden work.

On Monday morning, June 7, Sir Daniel Morris in the chair, Mr. H. A. Ballou (Entomologist to the Department of Agriculture for the West Indies) opened a discussion on "The Resistance of Plants to Insect Attacks." He believed that in many cases perfectly healthy plants do not afford the best possible conditions for the life of sucking insects, while the food supply derived from weak or diseased plants may stimulate insects to abnormally quick growth and prolific reproduction. This view was supported by the infestation of thrips on cocoa-trees in the West Indies. Prof. R. D. Watt emphasised the possibility of finding strains of cultivated plants immune from insect attack, analogous to those now well known in certain cases as immune from fungus pests. Mr. C. C. Gowdey (Uganda) considered good cultural methods as of great importance in maintaining the resistant conditions.

A cognate subject, "Artificial *versus* Natural Methods of Control of Insect Pests," occupied the conference on Wednesday morning, June 9, when Prof. R. Newstead presided. Mr. F. W. Urich (Trinidad) opened the discussion with an account of various measures adopted in the West Indies, of which the distribution by means of spraying machines of fungus spores for the destruction of cercopids on sugar-cane was the most remarkable. Dr. Tillyard regarded spraying with insecticides as an imperfect palliative, and looked hopefully for results in poisoning aphids and scale-insects from the inoculation of trees with such substances as copper sulphate. Mr. F. Balfour Browne uttered a warning against the possible danger of introducing parasitic insects into new countries in order that they may prey upon previously introduced plant-feeding insects, but Prof. H. Maxwell Lefroy and Dr. A. D. Imms regarded any danger from this now-established practice as remote.

Several interesting papers on more special subjects were read. On the afternoon of Monday, June 7, Mr. G. E. Bodkin gave his experience of the insect pests of British Guiana, and dwelt on the difficulty of controlling sugar-cane insects because of their habits of migration. On the same occasion Mr. F. W. Urich described the insect pests of Trinidad, and Mr. H. A. Ballou contributed a general review of conditions in the West Indies. On the afternoon of June 9 Dr. MacDougall lectured on "Insects in Relation to Afforestation," with lantern illustrations, pointing out the bearing of the feeding habits of common British timber- and bark-beetles upon practical questions of forest management. A discussion involving the uniformity of habit among insects of the same species in all parts of its range was carried on by Mr. C. F. C. Beeson (India) and Dr. Munro (Board of Forestry); the latter expressed regret that the Scottish and English Scolytidæ follow the rules laid down in the classical German text-books of forest entomology. Mr. F. A. Stockdale (Ceylon) followed with an account of the insect pests of tea in that island. On the afternoon of Wednesday, June 2, when Sir David Prain took the chair, Mr. H. H. Ballou read a paper on "Cotton Pests," dwelling particularly on the boll weevil and the pink bollworm, the latter of which caused a loss of 10,000,000*l.* in Egypt in the year 1917. Cotton insects are controlled by destroying at the end of the season all material in the field in which the species might survive until the next season. Mr. H. H. King described the organisation of entomological work in the Anglo-Egyptian Sudan, and stated that nine field laboratories under the charge of trained entomologists would be necessary for the proper working of the area.

Of the special questions discussed the most noteworthy was the tsetse-fly problem, considered at the meeting on Saturday morning, June 5, appropriately presided over by Sir David Bruce. Several entomologists from Africa spoke, including Messrs. R. W. Jack (South Rhodesia), Dr. A. May (North Rhodesia), and Mr. Ll. Lloyd and Dr. G. D. H. Carpenter (Uganda). An experiment as to the effect on the fly of the clearance of "big game" from a district in Rhodesia is now being tried. The opinion was expressed that the result of this will be disappointing, as mammalian blood forms, as a rule, only a small proportion of the food-supply of Glossina. Dr. Carpenter informed the meeting of the success which had followed the erection of inclined screens, under which hundreds of puparia are found; this means of control was suggested by an observation of the large number of puparia present in the shelter of a blown-down tree.

The conference concluded on Friday, June 11, with a business meeting, at which several resolutions were passed; these may be briefly summarised. (1) A conference should be held in London every five years. (2) The Imperial Bureau of Entomology should be established permanently; the cessation or curtailment of its work would be deplorable. (3) The Governments contributing to the expenses of the Bureau should be urged to guarantee their contributions. (4) The funds at present contributed for the upkeep of the Bureau are inadequate; they should be increased so as to provide an income of at least 13,000*l.* a year. (5) The Colonial Secretary should be requested to establish a provident fund for the Bureau staff. (6) The director and committee of the Bureau should have full power to exercise their discretion as to the scope and contents of the publications and the expenditure involved. (7) The director should encourage members of the staff to pay attention to particular groups of insects, especially those for the identification of which no specialist is available. (8) The provision of an adequate number of trained men to carry into effect existing plant-import legislation is of more immediate importance than the revision or extension of such legislation.

Members of the conference had the privilege of attending meetings of the Linnean, Zoological, and Entomological Societies, as well as the Staff Conversazione at the Natural History Museum. These gatherings, in addition to the three whole-day excursions to Rothamsted, Oxford, and Cambridge, gave welcome opportunity for informal discussion and pleasant social intercourse. Much gratification was felt and expressed at the presence for the first two days of Dr. L. O. Howard, Entomologist of the U.S. Department of Agriculture. His brief, pointed remarks at some of the discussions were much appreciated; he deplored some recent attempts to destroy "entomology" as a specific economic subject by dividing its subject-matter between "parasitology" and "phytopathology." All who participated in the conference appreciated the untiring efforts of Dr. G. A. K. Marshall and Dr. S. A. Neave, of the Imperial Bureau, who before and during the meetings did their utmost for the success of the gathering.

On the evening of the closing day the members of the conference were entertained to dinner at Lancaster House by H.M. Government, Viscount Harcourt presiding. Thus was pleasantly and fittingly demonstrated the increasing recognition of the importance of the study and practice of science in relation to the interests and industries of the Empire.

G. H. C.

The Selous Memorial at the Natural History Museum.

THE movement started in 1917 to perpetuate the memory of the late Capt. F. C. Selous, D.S.O., by a national memorial achieved its aim on Thursday, June 10, when Mr. Edward North Buxton, vice-chairman of the Memorial Committee, himself a great hunter in his day, in the unavoidable absence of the chairman, the Right Hon. E. S. Montagu, M.P., unveiled at the Natural History Museum, South Kensington, a bronze bust of Selous—the work of Mr. W. R. Colton, R.A.—before a distinguished and representative gathering.

The bust is mounted in a niche of grey granite from the Matoppo Hills, the burial-place of Cecil Rhodes and Sir Starr Jameson, and is the gift of the Union Government of South Africa. It was brought to this country by the Union Castle Line free of all charges. Below the bust is a bas-relief, also in bronze, depicting a lion and lioness, and in the distance an elephant, a situtunga, and other big-game animals, symbolical of the interests of the great sportsman and explorer. The granite bears the inscription: "Captain Frederick C. Selous, D.S.O., hunter, explorer, and naturalist. Born 1853. Killed in action at Beho-Beho, German East Africa, 4. i. 1917."

Mr. Buxton in his speech referred to the qualities of Selous which had endeared him to so many friends, and summarised these when he said that "Selous was a great hunter, and a still greater gentleman." On behalf of the committee he asked Viscount Grey of Fallodon, K.G., and the other trustees of the museum to accept the memorial and to preserve it in the museum for all posterity.

In his reply Lord Grey stated that in the museum, which was a national institution, this national memorial would be kept and honoured as a memorial to one who was a great explorer, a great traveller, a great hunter, and, besides that, a most brave and single-minded and attractive character.

The King sent a message to the effect that he felt that no more appropriate place than the Natural History Museum could be selected for a memorial to Capt. F. C. Selous.

It is indeed in the fitness of things that this memorial should have found a permanent place in the museum; for, next to his own home, there was no place in England which more attracted Selous than the museum, and when he was in this country he seldom kept away from it for more than a week; sometimes he was a daily visitor.

A guard of honour composed of officers and men of the Legion of Frontiersmen, many of whom had served with Selous in East Africa, and a detachment of the Kensington Division of Boy Scouts were present.

The response to the committee's appeal for funds for the memorial has been so widespread and generous that they have been able to provide a sum of money for the foundation of a substantial Selous scholarship at his old school, Rugby, on the basis that preference will be given at each election to the sons of officers who have fallen in the war, and in this connection

The Selous Memorial Bust in the Natural History Museum. On the right hand side of the memorial, not shown here, is the following inscription:—"Captain Frederick C. Selous, D.S.O., hunter, explorer, and naturalist. Born 1853, Killed in action at Beho-Beho, German East Africa, 4.i.1917."

it is with special satisfaction that we learn that in the examination for the scholarship a love and knowledge of natural history on the part of the candidate will be the deciding factor.

A few words may be said respecting Mrs. Selous's gift to the nation of her husband's splendid collection of big-game trophies and of birds' eggs, a gift for which Viscount Grey, on behalf of the trustees, conveyed to the donor his warm thanks, and at the same time expressed his high appreciation of its value and importance.

The collections have now been received at the Natural History Museum, and the big-game specimens are in course of being catalogued by Mr. Guy Dollman. We understand that it is the intention of the trustees to publish this catalogue, a work which cannot fail

to be of abiding interest to naturalists and sportsmen. The collection consists of 550 specimens—the greater part from South and East Africa—of splendid heads. It also includes nineteen magnificent lion-skins and a skull of the South African white rhinoceros—an extinct species—with exceptionally fine horns.

The collection of birds' eggs consists of 7010 specimens obtained in Great Britain, Europe, and Asia Minor. The great feature of the collection is that Capt. Selous personally took every egg from the nest himself. He would never accept any egg or clutch of eggs offered to him by a friend, nor would he purchase one from a dealer.

At the summons of a friend announcing the discovery of some rare bird's nest he would often travel very long distances, *e.g.* from one end of the British Isles to the other, in order that he might personally identify the parent birds and personally take the eggs from the nest. For this reason, no less than for the amazing neatness and methodical care with which it was arranged, to say nothing of its comprehensive range, the collection is a particularly valuable one.

University and Educational Intelligence.

BIRMINGHAM.—On the advice of Sir John Cadman, whose appointment as a technical adviser to the Government on matters relating to coal and petroleum is announced, the department of mining is to be reorganised and extended. In addition to the new professor of mining there is to be an assistant-professor of petroleum technology. It is hoped that Sir John Cadman will still retain some connection with the faculty of science.

Prof. F. W. Burstall has been elected dean of the faculty of science, to succeed Sir John Cadman.

CAMBRIDGE.—As briefly announced last week, a scheme for endowing a school of biochemistry has been approved by the High Court of Justice, and has now been submitted to the University by Sir Jeremiah Colman, Bart., on behalf of the trustees of the late Sir William Dunn, Bart. The residuary estate of Sir William Dunn was left in trust for certain charitable purposes, including the alleviation of human suffering. The trustees propose, with that object in view, to encourage and endow with the substantial sum of 160,000*l.* the study of biochemistry, one of the fundamental sciences of medicine, the progress of which is essential to the advance of medical knowledge. Having regard to the fact that the study of biochemistry in this country had its first beginnings in Cambridge, and is at present being carried on there without endowment under Prof. Gowland Hopkins, the trustees offer the University 165,000*l.* to found the Sir William Dunn School of Biochemistry. Of this sum they allot 25,000*l.* to endow a professorship and 10,000*l.* to endow a readership in biochemistry, the balance to be used in erecting and equipping an institute of biochemistry and in providing funds for its maintenance and upkeep and an endowment for research work.

This munificent benefaction is a most pleasing tribute to the work of Prof. Hopkins and his colleagues.

Dr. T. G. Adami, Vice-Chancellor of Liverpool University, has been elected honorary fellow of Jesus College.

Mr. J. E. Littlewood, Trinity College, has been appointed Cayley lecturer in mathematics, and Mr. J. H. Grace, Peterhouse, has been re-appointed University lecturer in mathematics.

The Special Board for Mathematics has recommended the substitution of thermodynamics for elementary optics in Schedule A of Part II. of the Mathematical Tripos.

In connection with the coming meeting of the British Medical Association at Cambridge, honorary degrees are proposed for the Master of Pembroke, Sir T. Clifford Allbutt, Jules Bordet, A. Calmette, H. Cushing, S. Flexner, Piero Giacosa, Major-Gen. Gorgas, Sir George Makins, Sir Patrick Manson, and Sir Norman Moore.

LIVERPOOL.—The council of the University has appointed Mr. T. R. Wilton as lecturer in dock and harbour engineering, with the title of associate-professor. Mr. Wilton is closely connected with the Liverpool Engineering Society, and has done valuable work for that body as hon. secretary—a position he has held since 1907. He has been for some years special lecturer in dock and harbour construction at the University, has carried out important investigations on the movement of sand and currents, and has also taken observations of a practical nature on the Mersey.

MR. H. RICHARDSON, of the Municipal College of Technology, Manchester, has been appointed principal of the Bradford Technical College in succession to Prof. W. M. Gardner.

THE Ministry of Agriculture and Fisheries is open to receive until July 15 nominations for a limited number of research scholarships in agricultural science, each tenable for two years, and of the annual value of 200*l.* Candidates must be graduates with honours in science of British universities, with evidence of high proficiency in subjects having a direct bearing on agriculture, and be nominated by a professor or lecturer of a university or college. Nomination forms are obtainable from the General Secretary of the Ministry, 72 Victoria Street, S.W.1.

THE *Library Association Record* for May contains a paper on "Technical Libraries and Intelligence" by Major W. E. Simnet, and also an article on "The Technical Library" by Mr. R. Borlase Matthews. Mr. Matthews lays stress on the necessity for making the most recent publications immediately available for reference, and discusses the various ways in which a technical library can be made accessible to readers. Major Simnet, taking the subject of engineering as an example, points out that there are at present in London several libraries containing books and periodicals relating to engineering, and that this involves much overlapping which might be avoided by amalgamation. He also refers to the Transport Library to be formed by the Ministry of Transport. Such a library would be devoted to all aspects and methods of transportation. The importance of an index of technical literature, possibly on the lines of the International Catalogue of Scientific Literature, is carefully explained by Major Simnet, who recommends a combination of indexing and abstracting. At the same time he finds that papers on technical subjects become out of date much sooner than papers on purely scientific topics, so that it is less necessary to preserve all titles of technical papers in a permanent index. Major Simnet gives an account of the *Technical Review*, established since the armistice to continue the work of the *Technical Supplement*, published in 1918 under the auspices of the War Office. As a further contribution to the indexing of technology, the *Library Association Record* for May, 1920, contains a subject-index to papers published in 1917–19 on fuel, including gas and petroleum. The list is prepared by the editors of the "Subject Index of Periodicals," and is an example of the thoroughness which their work always exhibits.

One of the problems at present confronting the Ministry of Agriculture is the provision of advice and supervision for the smallholder. This problem has become more acute now that so many of the men settling on the land are lacking, either partly or altogether, in knowledge of the theory and practice of horticulture. When the question arose of appointing organisers to instruct these men and to look after their interests, it was found that the number of candidates qualified to fill such posts was extremely limited. A man who is to organise the horticultural instruction of a county should have a knowledge of the scientific side of the subject as well as of its practical side. Quite apart from this question of supplying instruction for smallholders, it is obviously desirable, in view of the rapidly increasing importance of horticulture in this country, that the prospective fruit-farmer or market-gardener should be able to obtain instruction in his subject as scientific and comprehensive as that which can be so readily obtained nowadays by the prospective agriculturist. In order that such instruction may be available, the Ministry of Agriculture has made it possible for the University of Cambridge to establish a degree in horticulture and a post-graduate diploma. The course for the degree will extend over three years, and will consist of instruction in the theory and practice of commercial fruit- and vegetable-growing, the practical side of the subject being treated no less fully than its theoretical aspect. It is hoped that the course for the diploma will provide men qualified for research work in horticulture. Hitherto there has been a dearth of such men owing to difficulty in obtaining suitable training, and research work in connection with an important industry has therefore been greatly hampered. The courses will commence in October next, and information concerning them can be obtained from the Secretary, School of Agriculture, Cambridge.

Societies and Academies.

London.

Zoological Society, June 1.—Sir Sidney F. Harmer, vice-president, in the chair.—Dr. G. M. **Vevers**: Report on the Entozoa collected from animals which had died in the society's menagerie during the past nine months.—Dr. W. T. **Calman**: Notes on marine wood-boring animals. I.: The shipworms (Teredinidæ).

Cambridge.

Philosophical Society, May 17.—Mr. C. T. R. Wilson, president, in the chair.—Dr. F. W. **Aston**: The atomic nature of matter in the light of modern physics.

Manchester.

Literary and Philosophical Society, May 18.—Mr. R. L. Taylor, vice-president, in the chair.—W. **Thomson** and H. S. **Newman**: Further notes on the filamentous growths from aluminium amalgams. Experiments to determine the ratio of the mercury to 100 parts of alumina were detailed, and descriptions of erratic growths given. The action of mercury on zinc was compared with its action on aluminium.—Prof. Sydney **Chapman**: The effects of lunar tides on the earth's atmosphere. The barometric pressure shows a very minute tidal variation with the period of half a lunar day. This variation can be determined only by a difficult process of averaging out other regular and irregular variations from long series of hourly barometric observations, so that data from very few stations are available. The author described and discussed their theoretical significance. Many questions suggested by the data have as yet received no satisfactory answer, but their elucidation, as further data accumulate, should add to our knowledge of the atmosphere in some important respects.—Dr. R. S. **Willows**: Transverse section of cotton fibre illustrating Balls's daily growth rings.

Paris.

Academy of Sciences, May 31.—M. Henri Deslandres in the chair.—G. A. **Boulenger**: Remarks on the note of M. Ad. Davy de Virville concerning the species *Primula elatior, acaulis*, and *officinalis*.—Ch. **Gautier**: A sundial giving legal time throughout the year with a sufficient approximation for ordinary purposes, as well as the approximate date. The dial described and illustrated gives the legal time within about one minute. At the equinoxes it gives the exact date, but at the solstices only an approximation to the date.—Alex. **Véronnet**: The equilibrium figures of a liquid in rotation. Order of succession of the critical figures of bifurcation.—M. T. **Huber**: The generalisation of a theorem of M. Mesnager concerning the sense of the displacements of a rectangular plate.—J. **Fallou**: The expansion caused by Joule's effect at the contact of two solids. Two metals in contact when heated electrically expand proportionally to the square of the current or to the heat developed by the Joule effect.—A. **Guillet**: An auto-ballistic astronomical pendulum. An attempt to realise the conditions laid down by G. Lippmann and B. Baillaud, the impulses being supplied by induced currents.—M. **Girousse**: The calculation of currents causing electrolysis in metallic masses near an electric traction line.—F. **Vlès**: Contribution to the study of absorption based on the properties of the nitrophenols. By the application of formulæ given in a previous communication it is shown how the absorption spectrum of a compound can be calculated from its composition.—F. **Bourion**: Kinetic study of the chlorination of benzene. The effects of rate of supply of chlorine, concentration of the benzene in chlorobenzene, and of temperature upon the reaction velocity were examined separately.—L. **Vignon**: The resistance of tissues to light and ultra-violet rays. Linen and silk tissues were exposed to sunlight and to ultra-violet rays (Heraeüs quartz lamp) under dry and moist conditions, and the changes in the strength, as measured by the breaking load, determined. The silk fabric showed greater resistance than the linen to the effects of exposure.—E. E. **Blaise**: The action of hydrazine on the 1:4 acyclic diketones. Details are given of the products of the reactions between hydrazine and acetonylacetone and hydrazine and dipropionylethane.—A. **Gascard**: Ceryl alcohol and cerotic acid from China wax. The wax, after a preliminary purification, was saponified by potash in alcohol-benzene solution, the cerotic acid precipitated as calcium salt, and the ceryl alcohol recovered from the filtrate. Brodie's formula for the alcohol was confirmed by preparation and analysis of ceryl iodide, $C_{27}H_{55}I$, and for cerotic acid by oxidation of the alcohol and by its acidity figure.—A. **Guilliermond**: Observations on the living chondriome of one of the Saprolegniaceæ.—L. **Daniel**: A new race of Asphodelus obtained by the action of a marine climate. A description of the changes in type produced in *Asphodelus luteus* by twenty years' cultivation on the sea-coast. The modified plant can not only be reproduced by subdivision of the roots, but also by growing from seed.—P. **Ammann**: The great richness in nitrogenous matter of certain maniocs from Cambodge.—A. **Chevalier**: Researches on pear-trees, walnuts, and chestnuts of the cooler parts of Indo-China and the south of China.—E. **Foëx**: Necrosis of the stem of the potato attacked by the

disease potato leaf-roll.—P. **Portier**: Regeneration of the testicle in the pigeon deprived of vitamines.—A. C. **Hollande**: Œnocytoids and teracytes in the blood of caterpillars.—E. **Fauré-Fremiet**: The action of different chemical compounds on the pulmonary epithelial cell.—A. **Mayer**, H. **Magne**, and L. **Plantefol**: Reflex action produced by the irritation of the deeper respiratory tracts. The antagonism of this reflex with that caused by the irritation of the upper respiratory passages.—G. **Bertrand** and Mme. **Rosenblatt**: The action of chloropicrin upon yeast and *Saccharomyces vini*. A concentration of 1 milligram of chloropicrin per litre is sufficient to slow down fermentation by yeast, and 5 to 6 milligrams per litre completely arrests the production of alcohol. *Saccharomyces vini* is even more sensitive, growth being stopped by 1 milligram of chloropicrin per litre.

CAPE TOWN.

Royal Society of South Africa, April 21.—Dr. J. D. F. Gilchrist, president, in the chair.—L. **Péringuey**: Note on the whales frequenting South African waters. The author describes the various whales which are known to frequent the coasts of South Africa. The number of these is still under discussion. The fact is now well established that certain Northern whales are specifically identical with the Southern whales, and are the kinds of whales found on the South African coasts. That they are migrants, perhaps with the exception of *Balaenoptera Brydei*, is a well-established fact, but what is probably less known is that the animals go to warmer equatorial waters to breed or calve. If they are intercepted on their way there from the Antarctic or on their return the multiplication of the species will be greatly hindered, to say the least. People interested in the whaling industry admit that some measure of protection is necessary.—J. R. **Sutton**: Overgrowths on diamond. In this paper the author discusses in detail overgrowths of calcite, bort of various kinds, graphite, and diamond on diamond. Experiments were made with the object of determining why certain diamonds from yellow ground are not separated from the concentrates on the grease tables, the conclusion being reached that carbonate of lime readily forms a coating on a diamond surface, causing the diamond to behave like a common mineral in the pulsator gravel. A clear diamond is readily wetted by a solution of carbonate of soda, but not by pure water. Overgrowths of graphite and of black bort are common, and define per saltum stages of crystallisation. Thirteen specimens of "hailstone" structure are described. Laminated diamonds appear to be examples of overgrowth of diamond on diamond with interposing planes of colouring matter.—J. R. **Sutton**: Some statistics of thunder and lightning at Kimberley. The author gives tables of the results of eye and ear observations of thunder and lightning made at Kimberley during the twenty-three years 1897 to 1919, and classifies the storms according to the classification given by Ley. A phenomenon of interest is the "smell" of a thunderstorm. The author observed this only once strongly in Kimberley. European meteorological literature of the seventeenth and eighteenth centuries has many allusions to the "sulphureous smell" of lightning.—S. H. **Skaife**: Notes on some South African Entomophthoraceæ. The material used by the author was collected at Cedara, Natal, in 1919 and 1920. The great majority of the family are parasitic on insects. The author describes and figures South African species of Entomophthoraceæ and his experiments of cultivating them from dead and dying flies and grasshoppers and of infecting insects from the cultures.

Books Received.

Banff and District. By A. E. Mahood. Edited by Dr. E. I. Spriggs. Pp. xvi+388. (Banff: Banffshire Journal, Ltd.)

Diary of Societies.

THURSDAY, June 17.

Royal Society, at 4.30.—Prof. W. Bateson: Genetic Segregation (Croonian Lecture).

Linnean Society, at 5.—Celebration of the Centenary of Sir Joseph Banks, Bart. (1743–1820).—Dr. B. Daydon Jackson: Banks as a Traveller.—Dr. A. B. Rendle: Banks as a Patron of Science.—J. Britten: Banks as a Botanist.

Royal College of Physicians of London, at 5.—Dr. A. F. Hurst: The Psychology of the Special Senses and their Hysterical Disorders (Croonian Lecture).

Royal Society of Medicine (Dermatology Section), at 5.

Chemical Society (at Institution of Mechanical Engineers), at 8.—Prof. J. C. McLennan: Helium.

Harveian Society of London (at Medical Society), at 8.30.—Dr. E. G. Little: Differential Diagnosis of some Common Skin Eruptions.

Society of Antiquaries, at 8.30.

FRIDAY, June 18.

Institution of Sanitary Engineers (at Holborn Restaurant), at 11.30 a.m.—The President: The Institution and its Future.—A. J. Martin: Sanitary Socialism. At 2.30.—T. Robertson: Poured Concrete Construction.—G. W. Chilvers: Health, Wealth, and Housing.—A. P. I. Cotterell: A Glimpse at Domestic Engineering in some of the Eastern States of America.

Royal Society of Arts (Indian Section), at 4.30.—Sir Valentine Chirol: The Enduring Power of Hinduism (Sir George Birdwood Memorial Lecture).

Geophysical Committee (at Royal Astronomical Society), at 5.—Commander H. D. Warburg, Prof. H. Lamb, Dr. J. Proudman, Dr. A. T. Doodson, Major A. J. Wolff, and H. L. P. Jolly: Discussion on Tides.

Society of Tropical Medicine and Hygiene (Annual General Meeting), at 8.30.—Dr. F. H. Stewart: Recent Work on Round-worm Infection.

SATURDAY, June 19.

British Psychological Society (at University College, Gower Street), at 3.30.—Dr. J. Drever: The Emotional Phases of Affective Experience.

Physiological Society (at Physiological Laboratory, University of London, South Kensington), at 4.30.—G. Aurep and C. Lovatt Evans: The Mode of Action of Vaso-dilator Nerves.—C. Lovatt Evans: The Lactic Acid Content of Plain Muscle.

MONDAY, June 21.

Royal Geographical Society (at Æolian Hall), at 8.30.—Major L. F. I. Athill: Through South-west Abyssinia to the Nile.

Royal Institute of British Architects, at 8.30.

Aristotelian Society (at 74 Grosvenor Street), at 8.—Miss Beatrice Edgell: Memory and Conation.

TUESDAY, June 22.

Royal College of Physicians of London, at 5.—Dr. A. F. Hurst: The Psychology of the Special Senses and their Hysterical Disorders (Croonian Lecture).

Royal Aeronautical Society (at Central Hall, Westminster), at 8.30.—Comdr. J. C. Hunsaker: Naval Architecture in Aeronautics (Wilbur Wright Lecture).

WEDNESDAY June 23.

Geological Society of London, at 5.30.—O. Holtedahl: The Scandinavian "Mountain Problem."

Institution of Electrical Engineers (Wireless Section). (at Institution of Mechanical Engineers), at 6.—B. S. Gossling: The Development of Thermionic Valves for Naval Uses.

THURSDAY, June 24.

Royal Society, at 4.30.—*Probable Papers.*—Sir Ray Lankester: Some Rostro-carinate Flint Implements and Allied Forms.—Lord Rayleigh: A Re-examination of the Light scattered by Gases in respect of Polarisation. I. Experiments on the Common Gases.—A. Mallock: Note on the Influence of Temperature on the Rigidity of Metals.—Drs. E. F. Armstrong and T. P. Hilditch: A Study of Catalytic Actions at Solid Surfaces. V. The Rate of Change conditioned by a Nickel Catalyst and its Bearing on the Law of Mass Action.—Dr. H. Jeffreys: Tidal Friction in Shallow Seas.—Other Papers.

Linnean Society of London, at 5.—Dr. C. J. F. Skottsberg: Recent Researches on the Antarctic Flora.—Dr. R. J. Tillyard: The Cawthorn Institute, New Zealand, and its Biological Function.

Oil and Colour Chemists' Association (at Food Reform Club, 2, Furnival Street), at 7.30.—A. E. Bawtill: (1) A Hydrometer for Accurate Determinations of Pastes and Viscous Materials; (2 A Viscometer which Combines Increased Efficiency with the Power of Measuring "Stickiness" Independently of Viscosity.

FRIDAY, June 25.

Physical Society of London, at 5.—Dr. J. H. Vincent: The Origin of the Elements.—W. H. Wilson and Miss T. D. Epps: The Construction of Thermo-couples by Electro-deposition.—J. Guild: The Use of Vacuum Arcs for Interferometry.—S. Butterworth: The Maintenance of a Vibrating System by Means of a Triode Valve.

University and Higher Technical Education.

IN 1881 Mr. Mundella, then Vice-President of the Council, and consequently responsible for the policy of the Board of Education, with full knowledge as a manufacturer of the great growth, since the Franco-German war of 1870, of manufacturing industry in all parts of Germany, and sensible of the increasing unrest in British industry caused thereby, induced the Government of the day to appoint a Royal Commission "to inquire into the instruction of the industrial classes of certain foreign countries in technical and other subjects for the purpose of comparison with that of the corresponding classes in this country, and into the influence of such instruction on manufacturing and other industries at home and abroad." The members of the Commission were chosen from representatives of important industries and others engaged in scientific education. They undertook an extensive and exhaustive inquiry into the conditions and range of the teaching of pure and applied science in the chief European countries and in the United States, and visited also the Universities and colleges and some of the chief schools and workshops of the United Kingdom. After three years' investigation they produced in 1884 an exceedingly full and valuable report, which was widely circulated in this and other countries.

The report laid bare our serious deficiency as compared with the great facilities afforded by foreign Governments, especially those of Germany, Switzerland, and the United States, and it aroused a widespread interest in industrial and educational circles, leading, after a considerable lapse of time, to the passing of the Technical Instruction Acts of 1889 and 1890, which resulted in the establishment of many important technical schools throughout the kingdom.

We have undoubtedly made great progress in science and in its industrial applications during the past generation, but not less marked has been the advance of German industry, which in some spheres of manufacture, notably those of dyes and fine chemicals, in optical glass, and in certain branches of electrical engineering, easily held the first place. The events of the war have demonstrated the resourcefulness of British men of science, inventors, and manufacturers, who to a surprising extent, as shown by the exhibitions held, under the auspices of the British Science Guild, at King's College, London, in 1918, and at the Central Hall, Westminster, in 1919, met the extraordinary demand made upon their knowledge, ingenuity, skill, and adaptability. The time is now again ripe for inquiry as to the means and resources of the kingdom, especially from the point of view of a due supply of adequately educated and equipped men of science to be engaged in industry and commerce, to meet the inevitable industrial and commercial competition which will arise on the resumption of normal conditions and of free intercourse between nation and nation.

The strength of this competition may be illustrated in the instance of a highly specialised product. The balance sheets for 1919 of three of the principal aniline dye companies of Germany are now available. At the nominal rate of exchange, F. Bayer and Co. show a net profit of 1,450,000*l.*, against 654,000*l.* in 1918; Meister, Lucius and Co., 1,210,000*l.*, as compared with 750,000*l.* in 1918; whilst the Berlin Colour Works declare a dividend of 18 per cent., as against 12 per cent. in 1918. On the other hand, the sum available for dividend in the British Dyestuffs Corporation is only 172,505*l.* The report of this company states that there is an unprecedented demand upon it for dyestuffs in both quantity and variety, to meet which requires increased efforts in the direction of production and research. It is recognised that it is of paramount importance to have a department where research work can be carried out along the most modern and scientific lines, and to encourage those engaged on the scientific and research side of the industry.

The production of dyes of high quality in an endless variety of shades, in which the German firms have excelled because of their unlimited command of high-class scientific and technical ability,

the fruit of Germany's technical high schools and universities, is, like some other imported products, essentially a "key" industry, and therefore a dominant factor in the manufacture of finished textiles, which to a very large extent are exported by us to foreign markets, there to meet in competition the goods of other countries. Having regard to the prime necessity of increasing the supply of competent graduates for scientific industrial research, the British Science Guild carefully investigated the subject, and last year issued a report (which has been widely distributed to members of the Government, to the Universities, and to many leaders of industry and commerce) on industrial research and the supply of trained scientific workers. It was shown that in 1914 the number of full-time students of University standard and of students of science and technology in the United Kingdom was relatively small as compared with the number of similar students in the United States and in Germany; and further, that the financial resources of Universities in the British Isles are very much below those of the other countries. Two of the provincial Universities—namely, Manchester and Liverpool—are now engaged in the endeavour to raise the sum of 650,000*l.* and 1,000,000*l.* respectively to enable them to extend their operations so as to meet in some measure the demands made upon them, especially in the departments of science and technology. Leeds and other centres of higher education are also appealing for monetary aid.

There should be, as in 1881–84, a systematic national survey of the conditions now existing and of the requirements necessary to ensure the satisfactory progress of industry and commerce in the United Kingdom. The circumstances arising out of the war have brought about an entire and welcome change of outlook on the part of British manufacturers engaged in the chief industries of the country, evidence of which is to be found in the list issued in April last of nineteen research associations representing various industries which have been approved by the Department of Scientific and Industrial Research, whilst several other industries have submitted, or are engaged in preparing, memoranda and articles of association for approval.

The growing appreciation on the part of the community generally of the advantages of secondary education, together with the requirements of the Education Act of 1918, will of necessity increase the demand for highly qualified teachers, for whose training the Universities and the chief technical institutions will be responsible, necessarily entailing upon them a large additional expenditure. It is, moreover, increasingly recognised that the nation does not take adequate advantage of the best brains in the poorer classes of the community. A broad highway must [illegible] established along which they may travel [illegible] elementary school to the [illegible], but [illegible] can be accomplished only by the institution of a large number of national maintenance scholarships operating uniformly all over the country, as local scholarships do not, and so providing the means whereby the capable youth may advance from stage to stage from his twelfth year. This would entail a large expenditure, but the nation would be well repaid in the rich harvest it would reap of highly capable men and women.

These considerations lead to the necessity of largely increased State grants in support of University and higher technical education, which should be closely related to the appointment of a consultative committee mainly composed of representatives of industry and commerce and of universities and technical institutions to advise the Board of Education on matters relating to science and technology and their bearing upon the requirements of industry, and also to the division of the country into provinces roughly corresponding to the areas served by the respective Universities, governed by a council composed of existing local authorities, with the addition of members representative of the Universities and of industry and commerce.

If this were done it would be possible to correlate effectively all forms of education, to prevent overlapping, and to equalise the burden of administration and cost, whilst giving equality of opportunity, without distinction of class, to all residing within the province so created. For these reasons the British Science Guild strongly urges the Board of Education to set up a Departmental Committee to make an exhaustive inquiry into the present provision of University and higher technical education throughout the kingdom, with power to suggest how it could best be arranged and developed according to the needs of each area, whether industrial, commercial, or agricultural in character. Such an inquiry could not fail to be fruitful in its results, and would greatly stimulate the interest of all concerned in the conditions making for national well-being in all its aspects.

Mathematics of Elasticity.

Treatise on the Mathematical Theory of Elasticity. By Prof. A. E. H. Love. Third edition. Pp. xviii+624. (Cambridge: At the University Press, 1920.) Price 37s. 6d. net.

THIS is the third edition of the classical treatise in the English language upon the theory of elasticity, and all students of the subject will be grateful to Prof. Love for having brought his masterly exposition of this difficult but fascinating branch of mathematical science up to date. The book is now thoroughly well established as part of the education of such mathematicians as have to deal with the engineering or physical applications of elasticity; indeed, it needs some hardihood, even for a specialist, to criticise it; every fresh perusal convinces the careful reader of the inadequacy of his own knowledge.

The changes made in this edition have been slight in appearance, but attention to details will reveal many improvements in both form and matter. The numbering of the sections has not been changed, which is of great help to those students who have learnt to use the second edition. New sections have been interpolated here and there, and these have been distinguished by a letter—*e.g.* 79A.

As previously, a great many references are given to the experimental side of the subject, and very rightly, for in many ways the mathematical theory of elasticity is more closely verified by experience (where verification has been seriously attempted) than the cognate theory of hydrodynamics. Where discrepancies have occurred they can usually be traced either to the inherent difficulty of obtaining an exact mathematical solution of the problem, or to unintelligent experimenting. Far too much experimental work, for example, has been done with systematic disregard of the elastic limits, or without due precautions, in anticipation of 5 per cent. accuracy. For various reasons, the engineer does not find it convenient to *isolate* effects, and he rarely carries out experiments for the express purpose of testing a mathematical theory. Thus what may be called the *physics* of elasticity has advanced comparatively little. The methods of photo-elasticity, first used by Clerk Maxwell, who applied the effect of stress on polarised light (discovered by Brewster) to the investigation of stress-distributions, and recently developed as a working engineering method by Prof. Coker, promise to do much to remove this reproach and to get rid of the difficulty mentioned by Prof. Love that "the components of stress or of strain within a solid body can never, from the nature of the case, be measured directly" (p. 94).

New sections have been added in chap. iv. on the results of Hopkinson and Sears concerning stresses maintained for a very short time, and also on elastic hysteresis. The term "perfect elasticity" to denote that condition in which the stress-strain diagram is closed, although the loading and unloading graphs do not coincide, seems unfortunate, as elasticity can scarcely be called perfect when elastic energy is being dissipated. "Perfect recovery" might denote this case, "perfect elasticity" being reserved for the condition in which loading and unloading graphs coincide. "Linear elasticity" explains itself, but surely the statement on p. 113, given on the authority of Bauschinger, that the limits of linear elasticity are higher than those of perfect recovery, can scarcely be right, since the former condition should imply the latter. An important appendix has been added at the end of chap. ix. on Volterra's theory of dislocations in the case of multiply connected bodies. A simpler proof of Weingarten's theorem that the discontinuities in the displacements on crossing a "barrier" correspond to a rigid body displacement can, however, be given. For if u_0, v_0, w_0 be one value of the displacement at a point P, and u_1, v_1, w_1 the displacement at the same point P after describing an irreducible circuit, u_1-u_0, v_1-v_0, w_1-w_0 are solutions of the equations of elasticity which necessarily (since the strains are supposed one-valued) correspond to zero strain everywhere, and such displacements must be rigid-body displacements. In this connection it would make things clearer for the beginner if in the proof of the uniqueness theorem given in § 118 the limitations as to the nature of the functions and the simply connected quality of the space were stated. Todhunter and Pearson have pointed out that the existence of more than one solution for a multiply connected body is immediately evident to anyone who turns a short piece of indiarubber tubing inside out. The realisation of this fact is apt to shake the student's faith if warning has not been given.

In the chapter on the sphere a very valuable new section gives the alternative method developed by the author in his essay on "Some Problems in Geodynamics," and another section gives a number of new and important references to work on geophysical problems, a branch of elasticity which is assuming nowadays an increasing importance. The work of Lamb and of G. W. Walker in connection with seismology is noticed on p. 314.

§§ 226A and 226B deal with the torsion of a

bar of varying cross-section and with end-effects in torsion.

In the chapter dealing with the elastica, the section (265) which gives the computation of the strain energy of the strut has been practically re-written and much improved. It might be useful, in dealing with buckling, to dispose of a fallacy common among engineers that Euler's limit implies *failure* of the strut, whereas all that occurs is passage from one type of stable equilibrium to another.

Southwell's method of dealing with problems of elastic stability comes in, naturally, for consider-able notice. The buckling of a strut (§ 267A), of a rectangular plate (§ 332), and of a tube (§ 341) are discussed as examples of this theory.

An entirely new chapter (xxiv. A) has been added, dealing very exhaustively with the equi-librium of thin shells in the shape of surfaces of revolution, including in particular a discussion of Meissner's work on the spherical and conical shells.

A feature of this edition (as of the previous ones) is the extraordinarily complete and careful set of references to all the original papers and memoirs dealing with the subject. Needless to say, these references, which have been most thoroughly brought up to date, are invaluable to the reader who takes up the book as a guide to research. The example set by such a master as Prof. Love might well be commended to the younger generation of scientific writers. Too often nowadays, especially in papers dealing with applied science, one comes across a statement of references which betrays the author's ignorance of the literature of his subject, both by the omission of work (sometimes of fundamental importance) done by his predecessors, and by the undue prom-inence accorded to the minor efforts of contem-poraries in his own circle. L. N. G. F.

Behaviourism.

Psychology from the Standpoint of a Behaviorist. By Prof. John B. Watson. (Lippincott's Col-lege Texts.) Pp. xiii + 429. (Philadelphia and London: J. B. Lippincott Co., 1919.) Price 10s. 6d. net.

THERE has been a great deal of controversy, especially in the philosophical journals of America, concerning the theory of behaviourism. Prof. Watson is, we believe, the originator of the term and the recognised leader in its application as a method in psychology. The book before us is not an exposition of the theory; it takes it as accepted, and puts forward an elementary, but nevertheless complete, schematic outline of the science of psychology, its scope and its method, regarded from this point of view. It therefore, better than any detailed exposition, sets before us the advantages and the disadvantages, the limita-tions and inclusions and exclusions, of psychology as the behaviourist conceives it.

Behaviourism is a theory of the science of psychology based on two postulates. The first is that the only thing the psychologist can study scientifically is behaviour. The second is that there is nothing else in psychology to study but behaviour. When the description of an in-dividual's behaviour is exhausted there is no remainder, no psyche, left out of the account. The first postulate is explicit, the second implicit. It is clear at once, however, that the second is fundamental. Analyse the response of an organ-ised material being to the stimulus of a situation, and you have exhausted psychology. Not only have you gone as far as you can go, but there is also no farther to go.

When you have simplified your science to this extent, the difficulty is to justify it at all. What is the subject-matter of psychology which demands a special method? This is Prof. Watson's difficulty. Physiology is already in the field; it has accomplished a vast amount of this very behaviour study. What is there left over for psychology? What sort of responses are there to which the physiologist can be, and is, completely indifferent, and which fall under the class-heading, psychological? The further we read in this book, the more intensely does this inquiry present itself as the crucial question. Three chapters of the book (no inconsiderable portion of the whole) are acknowledged to be pure physiology, and not psychology, and the reader is told in the preface that he may skip these if he likes, and that if he does so he need be at no disadvantage from his point of view as psychologist. But the physiology is not all so easily excised. When Prof. Watson defines an emotion he has to apologise for the impossibility of avoiding physiological terms. How much, one wonders, would be left of the book if all the physiology were taken out and only pure psycho-logy left? The present writer, at least, as he reads the book finds himself in continual expecta-tion that now he is coming to the end of the physiology and the beginning of the psychology, but is continually disappointed, and the reason is clear enough when Prof. Watson gives at last his definition of the distinction of the two sciences. Whenever, he tells us, we are study-ing the response of a part of the organism to a

situation we are in physiology; only when we study the response of the whole organism to a situation are we in psychology.

So then it is like this—there are two sciences, let us say, of a motor-car, one in which we study the structure and function of the carburettor, the gear-box, the magneto, etc., and another and different science, in which we study the behaviour of the complete car on the road, its hill-climbing power and its responses to the varying situations consequent on the control of the traffic. No doubt there are people who can drive a car in absolute ignorance of the mechanism they are controlling, and in like manner there may be psychologists with complete knowledge of the responses of the individual, though ignorant of the mechanism of the reflexes on which those responses depend. Neither is to be commended; but can we rest satisfied with such a distinction? Is it not false science to separate the science of the parts from the science of the whole? Can the parts mean anything in abstraction from the whole, or the whole mean anything in abstraction from the parts? This, however, seems to be the behaviourist's idea of the subject-matter and scope and method of psychology and of its relation to physiology.

If your interest is in psychology, surely what you want to study is the subject of experience in its living, conscious, self-active subjectivity. You can, easily enough, regard such subjects of experience as objects, accurately describe their behaviour in varying situations, and formulate fairly useful scientific laws in regard to them, just as you may study the behaviour of a magnet in the neighbourhood of different substances and formulate magnetic laws. But is either scientific? Shall we, in the first case, discover by such a method the nature of imagery, conceptual thinking, apperception, perception of reality and unreality, ideality, rationality, and all the complex products of mental life, any more than in the case of the magnet statistical observations will lead us to discover the electro-magnetic constitution of matter? The essence of behaviourism is to translate the mental into terms of bodily integration and leave it there, satisfied that the work of psychology is now done. There is nothing beyond or different in its nature.

Behaviourism is not condemned by anything positive which it recommends, but by its absurdly extravagant claim that in restricting research to methods of observation and description it is actually making science all-inclusive. This book, for example, indicates numerous most useful experimental methods, and may inspire, and will direct, the student to practical researches of the highest interest to the advance of science. To this extent every psychologist will welcome it. It is difficult to find anything in its principle to disagree with, save only its limitation and negation. It is only when the behaviourist turns to us and says this is all there is—"Thought is the action of language mechanisms"—that we see that from his point of view there is no psychology.

H. WILDON CARR.

The World's Supply of Animal Foodstuffs.

Animal Foodstuffs: Their Production and Consumption, with a Special Reference to the British Empire. A Study in Economic Geography and Agricultural Economics. By Dr. E. W. Shanahan. (Studies in Economics and Political Science.) Pp. viii+331. (London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1920.) Price 10*s*. 6*d*. net.

THIS book provides a comprehensive and very interesting survey of the production and consumption of animal foodstuffs, considered especially from the economic point of view. An interesting historical survey is included, which starts with the use made of animal foodstuffs by earlier generations and traces the gradually increasing demand for, and consequent development of, the supplies of these materials. Part i. of the book gives a detailed survey of the production of the various animal foodstuffs in the more important countries of the world.

With regard to animal foodstuffs the author states that the following countries show a definite net surplus when the balance of imports and exports is taken by values, namely, the United States, Russia (with Siberia), Sweden, Denmark, Holland, and Italy. When, further, the net imports or exports of animal feedstuffs are considered in conjunction with those of animal foodstuffs, the following results are observed: The surplus position of the United States, Argentina, Uruguay, Canada, and Russia (with Siberia) becomes intensified, while the deficiency position of Great Britain, Germany, and Belgium becomes, similarly, more marked; at the same time the surplus position of Denmark, Holland, Sweden, and Ireland suffers reduction. The author discusses fully the influence on production of such factors as agricultural machinery, cost of labour, co-operation of farmers, etc. Part ii. deals with the consumption of animal foodstuffs, the rate of consumption, and the economic and other factors influencing that rate.

There has been a rapid increase in the meat-

consuming population of the world during the last fifty years. This increase amounts apparently to more than 90 per cent., and some further allowance should also, in the author's opinion, be made for the rise in the standard of living not only in Europe, but also in Asiatic and tropical countries. One of the chief causes for this increase appears to be the less frequent occurrence of devastating wars as compared with earlier times. Also the opening up of vast new regions of agricultural productiveness encouraged the growth of the meat-consuming population outside Europe, while the development of cheap transport, enabling the surplus foodstuffs and feedstuffs of these new countries to be carried to other regions where local supplies were deficient, had a great effect in making possible the increase of the industrial populations in Europe. From a study of the production and consumption of animal foodstuffs it becomes clear that the supply of these is likely to be considerably less than the demand. The author states that this is due to three causes: Owing to the comparative lack of undeveloped fertile regions, the rate of expansion in the surplus production of pasture-fed meat animals and of concentrated feedstuffs from the new overseas countries is slowing down; the white meat-consuming population has increased; with the general improvements in the financial status of industrial and agricultural workers in Europe, their *per capita* consumption of animal foodstuffs tends to rise.

Part iii. of the book is concerned with the above problems as they affect the British Empire. The study of the Empire's deficiencies, both in animal foodstuffs and feedstuffs, points throughout to its lack of widespread intensive systems of agriculture, for, though land resources are abundant, they remain more or less undeveloped in large areas. The author emphasises the fact that throughout those parts of the Empire inhabited by white people only a relatively small proportion are engaged in agriculture, and they work on the extensive instead of the intensive system. His conclusion is:—

"The Empire, as a whole, requires to have an enormously increased area under cultivation for the production of feedstuffs, not only to make good its deficiency in this direction, but also to provide for the maintenance of food-producing animals and of poultry in much larger numbers than at present, if it is to cover in a more satisfactory way its deficiency in meat, dairy produce, and eggs."

A valuable feature of the book lies in the summaries which occur at the end of nearly every chapter in Part iii., while for Parts i. and ii. the author gives a full summary of the conclusions to be drawn from the general study of the question of food production and consumption.

Life and Lore of Birds.

The Heron of Castle Creek and Other Sketches of Bird Life. By A. W. Rees. With a memoir of the author by J. K. Hudson. Pp. xi+218. (London: John Murray, 1920.) Price 7s. 6d. net.

A MELANCHOLY interest is attached to this volume, inasmuch as its gifted author selected the articles, which had previously appeared in various serial publications, for re-issue in book form, but did not live to complete their final revision for the press. This task was undertaken by his literary executor and successfully carried through with so satisfactory a result that we are glad to know that sufficient of Mr. Rees's writings still remain to form another of these delightful volumes.

Most of the essays in the series now before us are devoted to bird-life, the various phases of which are graphically described from the personal observations of the author, who did not trust to books for his knowledge, but gleaned his information at first hand from the creatures he loved. The engaging style of writing and the accuracy of the author's notes on the lives and loves of the birds and beasts he watched disarm criticism and form engrossing reading. It is difficult to single out any particular essay as of outstanding interest, but the account of the parent kingfishers teaching their brood to dive for minnows is original, amusing, and instructive, while the observations on the dipper, the efforts of the author to find its nest, and the affection shown by these birds for their mates, entirely captivate the reader. When a cock offered his tribute of a large worm to his lady-love, the author felt, as he watched its antics, that he "could recognise a sentiment subtly different from mere animal passion," and goes on to say:—

"In those rare brief periods of outdoor study when, to my surprise and delight, I have caught a glimpse of what, for want of a better phrase, might be termed the humanity of Nature, I have not merely imagined, but have felt sure, that many of the finest feelings of man—pity, sympathy, devotion, unselfish comradeship—are shared in no small measure by creatures considered to be far beneath our plane of life."

Five essays are given on the life of the partridge at various periods of the year, and these

are so graphically penned that one fancies oneself at the author's side, watching intently the behaviour of these attractive birds, and sharing with them the hopes, fears, and passions incidental to all stages of their brief career in the open, fraught as it is with constant danger from hawk, weasel, fox, or sportsman, and yet alleviated by the intense joys inseparable from the sharing with a mate the important duties of founding a home and rearing a brood of tiny fledglings. The book is not without its humorous side too, as the reader will discover when smiling over the "Misadventures of Bird-watching." While the author is endeavouring to identify a pair of warblers and to find their nest, he is himself closely watched, in the first place, by a puzzled keeper, who suspects him of poaching, and, secondly, by an angry bull in unpleasant proximity, to escape the unwelcome attentions of which the enthusiastic naturalist has perforce to bring into action his fullest powers of strategy.

This well-printed and unusually attractive volume can be recommended to the notice of all lovers of Nature and Nature-lore, and the appearance of a further series of posthumous essays will be very welcome.

Our Bookshelf.

Engineering Descriptive Geometry and Drawing. By Capt. Frank W. Bartlett and Prof. Theodore W. Johnson. Part i. Pp. vii+206. Part ii. Pp. v+207–374. Part iii. Pp. v+375–617+xiv plates. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 27*s*. 6*d*. net.

THIS book gives in full detail the elementary courses of engineering drawing as taught to young midshipmen in the Navy of the United States of America. The instruction is arranged on the assumption that the student is quite without knowledge or experience in the handling of drawing instruments. Part i., occupying about a third of the volume, treats of line drawing in pencil and in ink, lettering, the use and care of instruments and scales, and describes in the minutest detail all the "tricks of the tool's true play" as witnessed in the practice of the draughtsman's art. In these pages the learner has virtually at his elbow, for constant reference, the skilled craftsman and the experienced teacher. His progress should be sure and rapid, even without much help from an instructor.

In part ii. the principles of projection and descriptive geometry are unfolded in close relation to the special needs of engineers.

Part iii. is perhaps the most important section, and the fourteen plates at the end give standard dimensions of such things as bolts, nuts, rivets, pipes, rolled sections, etc., as adopted by the bureaux of the U.S. Navy Department. We have in this part a finely graduated scheme of work in which the student executes finished drawings of machine details from his own dimensioned hand sketches of the actual parts; becomes familiar with the tables of standards; is trained in the reading of drawings, etc. Although the instructions are again minute and full, almost sufficient for self-tuition, there is no suspicion of spoon-feeding, and the student is left more and more to his own resources as he becomes fit. There are chapters on ships' lines and on structural steel and iron work.

The treatment of the subject has been evolved gradually and embodies the results of much experience in class work. It is characterised by thoroughness, and the text-book is a model of what such a book should be. The volume ought to be in the library of every technical school and drawing class in this country. Teachers as well as students could learn much from it.

Intermediate Text-book of Magnetism and Electricity. By R. W. Hutchinson. Pp. viii+626. (London: W. B. Clive; University Tutorial Press, Ltd., 1920.) Price 8*s*. 6*d*.

THE writer of a book such as this is a little handicapped by having to work in accordance with schemes laid down by boards of examiners, and has not quite a free hand in the arrangement and development of his material. Covering the subject up to the "Intermediate" standard, the work is suitable more to the science student than to the future electrical engineer, and in view of the vastness of the field the author has been obliged to cut down the practical parts of the subject in order to provide space for the more academical sections. It is not his fault that the pith ball is made as important as the dynamo. Nevertheless, we would urge that it is as essential for the science student as for the engineer to "think in volts and amperes" before he attempts to grasp subtler refinements, and we should have liked to see Ohm's law and the conception of resistance introduced earlier than p. 304. In the author's treatment of magnetism, on the other hand, with which he commences his volume, he boldly brings his reader face to face with the equation $B=4\pi I+H$ as early as p. 31, adopting "an introductory elementary treatment to acquaint the reader with the general meaning of the terms in use," and giving the fuller treatment in its proper place later. The idea is excellent, and a similar scheme might have been applied to electric currents with advantage.

Taken all round, the work is painstaking and is skilfully compiled. Special attention should be directed to the three concluding chapters on electrical oscillations, passage of electricity through gases, and radio-activity respectively, which form admirable introductions to the portions of the subject founded on the more modern researches in physics.

A Junior Course of Practical Zoology. By the late Prof. A. Milnes Marshall and the late Dr. C. Herbert Hurst. Ninth edition, revised by Prof. F. W. Gamble. Pp. xxxvi+517. (London: John Murray, 1920.) Price 12s. net.

THE principal change in the new edition of this admirable and well-established text-book is the substitution of *Dipylidium caninum* for Tænia as an example of a tapeworm. This change has no doubt been determined largely by the common occurrence of Dipylidium and the consequent facility in obtaining sufficient material—especially scolices—for class purposes. The account is illustrated by a page of good figures, but there is an error in the magnification given for Fig. 3. From the point of view of the organs of the segment, Dipylidium—with two sets of reproductive organs in each segment, and the uterus subdivided into capsules in the mature segment—is not so good as Tænia as a type for study by junior students, and for the convenience of those teachers who prefer the latter type a brief description of the organs of the segment of Tænia might be added at the end of the account, together with Figs. 4 and 6 on p. 47 of the previous edition.

In spite of the care with which the book has been edited, a few slips have escaped attention—*e.g.* on p. 12 "Monocystis belongs to . . . the Sporozoa or Gregarines," as if these two terms—one relating to a class, and the other to an order in the class—were synonymous; there is the loose statement on p. 33 that in Obelia some of the buds "have no mouth and become medusæ"; and the amount of acid given in the formula for acid alcohol is incorrect owing to the omission of a decimal point.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Separation of the Isotopes of Chlorine.

MR. CHAPMAN'S conclusion (NATURE, June 17, p. 487) that the isotopes of chlorine should on certain assumptions be capable of separation by chemical means, is clearly wrong, unless there is something not stated in the reasoning to prevent it being applied to the case of a "pure" element, such as, for example, according to the results of Aston, fluorine actually is. Denoting an entirely imaginary difference between two kinds of fluorine atoms by F and F′, the reasoning seems to lead, in this case to the obviously absurd result that these two kinds of identical atoms with a purely imaginary difference must be capable of separation by chemical means.

The error appears to be in the equilibrium equation (i)

$$[Cl_2][Cl'_2]=[Cl.Cl']^2.$$

Mr. Chapman does not show how he deduces this, and it is of interest to know whether the error is due to a slip in the application of the theory of chemical equilibria to the case or to a fundamental flaw in that theory. In the present case, if the isotopes are assumed to be chemically identical and the distribution of the two kinds of atoms in the molecules due to pure chance, then if n is the fraction of Cl atoms and $(1-n)$ that of the Cl′ atoms, the fraction of Cl_2 molecules is n^2, of the Cl'_2 molecules $(1-n)^2$, and of the Cl.Cl′ molecules $2n(1-n)$. This gives

$$[Cl_2][Cl'_2]=\tfrac{1}{4}[Cl.Cl']^2,$$

which is in accord with the ratio 9 to 1 to 6, stated by Merton and Hartley for the case $n=0{\cdot}75$ (NATURE, March 25, p. 104), and with Mr. Chapman's own equation (iv) deduced from the assumption that the isotopes are non-separable. FREDERICK SODDY.

A Possible Cause for the Diamagnetism of Bohr's Paramagnetic Hydrogen Atom.

ONE of the difficulties which confronts Bohr's structure of the hydrogen atom is the fact that hydrogen, on his hypothesis, should be paramagnetic, whereas it is, like the majority of the simple gases, diamagnetic. Experiments on the magnetism of gases have, however, always been made above absolute zero, and the atoms must therefore be in motion; and if this motion involves vibrations and rotations of the atom as well as translatory movements, then it is possible for the atom to appear diamagnetic, although it may be inherently paramagnetic. In a paper on "The Mean Magnetic Moment and Mean Energy of a Vibrating Magnet" (Mems. Manchester Lit. and Phil. Soc., vol. lvii., 1913, No. 4) I considered in a simple case how such an effect might arise if a magnet were in a uniform field and free from the influence of neighbouring magnets. In these circumstances, when the vibrations exceed 130° on either side of the position of rest, or if the vibrations pass into rotations, then the magnet will appear to be diamagnetic, because the average time during which the positive and negative poles are in the diamagnetic position is longer than the average time during which they are in the paramagnetic position.

Honda (Phys. Rev., Ser. 2, xiii., 1919) has recently examined at length the effect of all the possible rotational movements of a magnet in his kinetic theory of magnetism, and, with certain assumptions as to the shape of the atom, comes to the same conclusion.

Applying this result to a paramagnetic atom, it is possible that such an atom, in virtue of its motion, may appear to be diamagnetic, and the fact that hydrogen is diamagnetic may be quite consistent with Bohr's paramagnetic model of the atom.

The kind of diamagnetism here considered, which may be called pseudo-diamagnetism, differs from that due to induced electric currents in the atom, which may be regarded as true diamagnetism. Pseudo-diamagnetism will be subject to variation with changes of temperature and with the state of aggregation of the atoms, while true diamagnetism is probably independent of these.

If the diamagnetism of hydrogen should be found to change at a very low temperature and in a very strong field, it would show that the diamagnetism of this gas was probably an effect of the motion of its atoms, and such a result would indirectly help to confirm Bohr's view of the structure of the atom by removing a difficulty. J. R. ASHWORTH.

Rochdale, June 8.

A Stalked Parapineal Vesicle in the Ostrich.

THE ostrich chick on hatching displays an oval, dark-coloured, bare patch towards the hind part of the head. Later, it tends to be hidden by the thick growth of hair-like feathers which cover the head

generally, but even in the adult it can always be recognised by turning the feathers aside. Its position suggests that it is in some way associated with the pineal body, and dissection reveals a large pineal gland directly beneath, though wholly cut off by the skull. Early stages in the developing chick disclose a yet more remarkable formation in the same region, which leaves no doubt that the bare patch is really a brow spot or pineal spot, the ostrich being the only bird in which a permanent structure of this kind has been described.

Ostrich embryos of about twenty-six days' incubation—the full period being forty-two days—display a

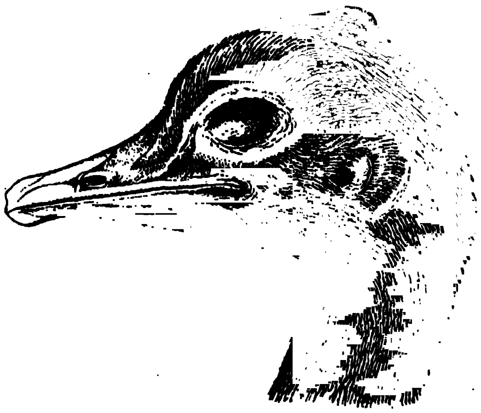

FIG. 1.

large pedunculate vesicle projecting from the middle of the bare patch, surrounded by developing feathers (Fig. 1). The stalk is thick, deeply pigmented, and rounded above, but irregular in outline below, while the vesicle is thin-walled and almost transparent, the whole structure strongly suggesting a stalked eye. The outgrowth persists for a few days only, but all ostrich chicks from about twenty to thirty days' incubation reveal one stage or another in its development or retrogression.

Microscopic sections through the fully developed organ reveal the condition represented in Fig. 2. The

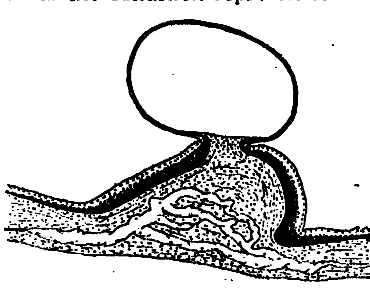

FIG. 2.

stalk is solid and broad below, with a thick epidermis produced into small, irregular fimbriations and deeply pigmented, while the vesicle is extremely thin-walled and filled with a coagulable fluid. The underlying dermal tissue is continued unchanged into the stalk, but below it has undergone a peculiar sclerose modification. The whole structure is thus tegumental and destitute of any special nervous or sensory elements. Beneath it, but not represented in the figure, is the well-developed pineal gland resting upon the pouch-like dorsal sac. Before the vesicle is fully formed, sections reveal that the basal part of the stalk is double, as if two stalks have become fused, but only one has elongated, and ends in the vesicle. At a late stage in retrogression the two components are quite distinct.

A pedunculate vesicle, arising from the middle of the head, renders the ostrich unique among birds as well as among the entire vertebrate series. Its general association, however, leaves no doubt that it is a part of the pineal complex. The latter has, therefore, been investigated from the earliest chick stage, and many significant features have been disclosed. The primary pineal vesicle or epiphysis appears about the third day of incubation as a simple, globular, median outgrowth of the roof of the thalamencephalon; later, it forms a dense follicular system, and communication with the third ventricle is lost. At the time of its formation a small, solid upgrowth takes place just anterior to it, and situated on the right side, afterwards becoming tubular and detached, and extending upwards and forwards over the left cerebral hemisphere. All the evidence points to this as a vestigeal parapineal organ, arising in close association with the pineal organ, but detached from it. It disappears about the tenth day of incubation. A paraphysial upgrowth arises in front of the velum transversum, but persists for a few days only, and a dorsal sac situated immediately under the pineal gland is strongly developed.

It is submitted that the vesicle is the embryonic, persistent, integumental covering of a stalked parietal eye which was present in the ancestors of the ostrich. The sensory part of cerebral origin has degenerated, as in all birds, but the protective corneal covering of transparent epidermis and dermis which would envelop it as it pushed its way upwards still reappears in the embryo, remains for a very brief period, and then retrogresses, the pineal patch being all that persists in later life. The unique stalked character of the eye is manifestly a peculiarity to be correlated with the presence of a covering of feathers in birds.

J. E. DUERDEN.

The Alligator Pear.

THE important notice of *Persea gratissima* in NATURE of May 27 may be usefully supplemented from Madeira, where, during the last sixty years, from ten or a dozen examples, the tree has become familiar in every garden enclosure on the lower 500 ft. of our mountain-sides—cultivated for its attractive form and autumnal yield of valuable fruit.

The revival of the short voyage from Madeira, three days and a half, to Southampton has restored the alligator pear to its former importance in the London market, for no other locality can offer equal facility for presenting this valuable esculent in condition to satisfy the educated palate of those who know the flavour of the fresh fruit.

Grown from seed, *P. gratissima* begins to bear fruit in from seven to ten years, attaining full maturity in twenty years, when it has grown into a spreading tree 30 ft. high or more, with dense light green foliage, maturing an abundant crop in September and October.

A single tree in full bearing will yield a market value of from 8*l.* to 15*l.*, and the rich nutty-flavoured fruit is in growing demand.

In Madeira no serious efforts have been directed to the improvement of the alligator pear, either by selection or grafting, and the large central seed still remains as a reproach to us; but the stimulus of increasing commercial value is at hand, and preference will be given to increased food value. Some years ago I suggested that the tree might be usefully grafted on to *Persea indica*, one of the four Madeiran laurels, much hardier and with greater range, hoping

thus to spread the pear-tree beyond its present limits and to obtain from a more robust stock an increased thickness of edible flesh, and perhaps improvement in flavour; and parcels of *P. indica* seed were sent to the southern United States to test this means of fruit development. But the wild Persea is fast disappearing from our forests through sheer improvidence, and its priceless pink-tinted mahogany will soon be extinct.

The alligator pear—the "midshipman's butter" of other days—is mainly eaten in Madeira as a breakfast-table fruit, generally with pepper and salt, and is especially to be commended as a sapid adjunct to a well-made salad, garnished with segments of the fruit as with hard-boiled egg, and sprinkled with the edible flowers of *Cercis siliquastrum* when available.

The Portuguese authorities will some day realise that the fertile valleys into which these mountain-slopes are cloven may be more profitably occupied than with sugar-cane by the custard apple, alligator pear, and other plants the perishable product of which Madeira only, from its situation, can supply in perfection to the European markets; and our perennial green peas, Cape gooseberries, February strawberries, hognuts, and broad beans will then be available in profusion while the Northern markets still wear their wintry aspect. MICHAEL GRABHAM.

Madeira, June 7.

Eye-Colour in Bees.

EVERY biologist is now familiar with the colour-variation in the eyes of Drosophila, and the remarkable contributions to biological theory which this variation has made possible. It is not so well known that among the Anthophorid bees there are striking differences in eye-colour, which must have arisen in a manner analogous to those of Drosophila. These differences usually characterise species; thus in the genus Centris one form has the eyes crimson, another green, another grey. In Anthophora two closely related species from New Mexico differ, one having the eyes green, while in the other they are dark purplish. There are other differences, and the species are quite distinct. I have just obtained evidence of mutation in eye-colour within the species. *Anthophora porterae*, Ckll., is a large species with clear green (olive-green or pea-green) eyes. The varieties *Watsoni* and *semiflava* agree with the typical form of the species in this respect. However, on May 23 of this year, at White Rocks, near Boulder, Colorado, Miss Marie Chandler found a male with the eyes dark bluish-green (sea-green). This may be called mut. Thalassina. On drying, after death, the eyes became grey marbled with black.

T. D. A. COCKERELL.

University of Colorado, Boulder.

British and Foreign Scientific Apparatus.

IT may be said at once with emphasis that British scientific instruments cannot be made in factories at the present wage-rates and under prevailing labour conditions at twice the pre-war prices if identical in quality and construction. Mr. Ogilvy discloses the same fact with regard to German instruments when he states in NATURE of June 3 that the wages rates of Germany are 400 per cent. higher than in 1914, and that working conditions are difficult in every way.

The only reason that German firms can sell in English money at from 60 per cent. to 100 per cent. above pre-war rates is on account of the benefit they have under to-day's rate of exchange, which values the mark at 1½*d.* only. It is obvious that German firms are doing remarkably well for themselves by selling in England at about twice the pre-war price.

The question is not one of free trade, prohibition, or import under licence, but whether the scientific instrument manufacturing of this country is to continue or not. It is recognised that scientific apparatus is a necessity to the nation, and should properly be maintained as a "key industry." The manufacturers have the courage and the enterprise, and have been making preparations for production by new methods on a large scale for many months under exceedingly difficult conditions, but with the assurance that some degree of protection would be given to them.

I have before me as I write an offer of 11,935 prism binoculars lying in London by leading German makers, all at the same price and far below the cost at which similar binoculars can be made in this country at the present time. This, surely, is a case of "dumping."

It must never be forgotten that the scientific instrument makers in this country were among the foremost in the production of precise instruments for the war. Works were enlarged and plant increased to make instruments of which the Government had never encouraged the manufacture in this country, preferring to buy from Germany in times of peace; and the more effectually a comparatively small firm did its work in war-time, the more it is handicapped now. Several firms are laden with premises and plant, and have excess profits liabilities which are difficult to meet in cash, while capitalists will not put money into scientific instrument manufacturing businesses under present conditions.

Production would be hastened on a scale commensurate with the needs not only of this country, but also of the world, if these facts were faced and met; and it is the opinion of scientific instrument makers that some degree of protection should be afforded during the period that the mark and the franc have such a depreciated value.

There are no "trusts" in the British optical world, as a correspondent in NATURE suggests; there is severe competition between all manufacturers.

British manufacturers have never been slow in throwing open their works for the inspection of those who are interested, and if your correspondents and readers could be induced to pay a visit to some of the works in this country and see exactly what is going on and the possibilities that exist, they might be led to take a view of the subject which would offer encouragement to the hardly pressed, but still optimistic, British scientific instrument maker.

If any readers of NATURE should wish to visit optical works, and would send a note to the secretary of the British Optical Instrument Manufacturers' Association, Ltd., 2–3 Duke Street, St. James's, arrangements would quickly be made.

F. W. WATSON BAKER.

(W. Watson and Sons, Ltd.)

Applied Science and Industrial Research.

PROF. SODDY and Major A. G. Church both say in NATURE of June 3 that my letter published on May 27 confuses the issue. It may be so: I have never known a controversy in which each side did not, sincerely, accuse the other of the sins of irrelevancy and confusion. I have no desire to enter on a detailed discussion of personal views. My sole aim was to raise certain principles that seemed to me in danger of being overlooked. I think Prof. Soddy's suggestion will meet the case: that readers of NATURE who are interested should obtain a copy of the full report of his address. They can then judge for themselves how much or how little occasion there was to justify my letter. J. W. WILLIAMSON.

3 Canterbury Mansions, N.W.6, June 12.

Wireless Telephony.

By PROF. W. H. ECCLES.

WIRELESS telephony has made such rapid progress during the past six or seven years that it must now be looked upon as a possible rival to wireless telegraphy for communication over distances up to a thousand miles. Although telephonic communication demands on normal occasions the expenditure of more power than does communication by Morse signs, yet the superior rapidity with which thought can be conveyed by voice transmission is a weighty advantage; and, besides, telephony often proves more successful than telegraphy when strays and analogous disturbances are bad, partly because the ear is so skilful in following the voice in the midst of other noises, and partly because the context greatly assists comprehension. Many of the recent improvements by which the present position in wireless telephony has been reached are due to the development of the thermionic vacuum valve with three electrodes—called, for short, the triode.

The essential difference between wireless telephony and wireless telegraphy is that the voice is used instead of the Morse key to produce alterations in the radiated electric waves. In continuous-wave wireless telegraphy the Morse key, and in wireless telephony the voice, may be applied in two ways: (1) for altering the wave-length, and (2) for altering the amplitude, of the oscillations in the antenna. A distant receiving station capable of sharp response to the normal wave-length of the sending station picks up less energy from the altered waves passing over it, whichever type of alteration is in use at the sending end; for if the amplitude at the sender is altered, the amplitude of the electric and magnetic fields produced at the receiver is changed correspondingly, while if the wave-length at the sender is altered, the receiving station responds less, because the incoming waves are out of tune with it. In many telegraph and telephone systems both types of alteration occur together.

Once the source of continuous waves is available, the main problem in wireless telephony is to provide means of exciting the transmitting antenna in accordance with acoustic vibrations produced by the voice. The process of moulding the oscillatory currents by means of the voice has come to be called "modulation," and the apparatus used, if distinct from the rest of the transmitting apparatus, is called the "modulator."

The obvious method of modulating a given high-frequency alternating current is to use the familiar apparatus of ordinary line telephony. In our ordinary line telephone services direct current is passed through a carbon microphone, and is constant in value so long as the granules in the microphone are quiescent, but when the granules are made to vibrate by the voice, the current is correspondingly modulated, and may be made to produce sound by the familiar telephone receiver consisting of an electromagnet and an iron diaphragm or reed. In wireless telephony the microphone may be used in a precisely analogous way by being placed in the antenna as shown in Fig. 1, or in an earlier circuit as shown in Fig. 2. In the apparatus of these diagrams the oscillatory current may come from an arc, an alternator, or a triode.

A different method of modulating a given source of supply was advocated, especially by R. A. Fessenden in America, early in the history of wireless telephony. The essence of this method was the employment of a condenser of which one surface could be moved relatively to the other by the voice, and this was usually associated with the antenna of the sender. Alterations of the electrical capacity of the condenser produce departures from resonance, and therefore alter the amplitude excited in the antenna by the source of oscillations. On the other hand, the condenser may be used in the circuit generating the oscillations, especially when the source is an arc or a triode, and in this case the frequency of the oscillations supplied to the antenna is modulated by the voice, and conse-

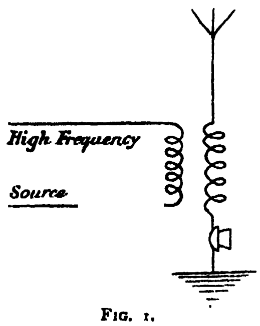

FIG. 1.

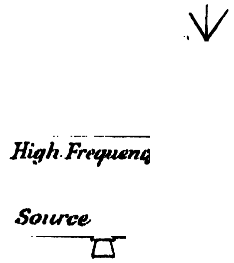

FIG. 2.

quently both amplitude and frequency of the oscillations in the antenna are modulated. The condenser has to be of special construction in order that its capacity shall be variable at a frequency of 1000 per second. In the recorded experiments it has consisted of a thin diaphragm placed very close to a fixed parallel plate, and the diaphragm has been acted upon either directly by the voice or indirectly by means of some magnified microphone currents passing through an electromagnet.

The above two methods accomplish modulation by variation of the resistance and of the capacity respectively of one or other of the oscillatory circuits. It is natural to consider the possibility of varying the remaining electrical magnitude—namely, the inductance, self or mutual. The variation of self-inductance has been employed by both German and American experimenters, but perhaps the most successful is that due to E. F. W. Alexanderson, of the General Electric Co. of America. In a broad sense this experimenter takes advantage of the dependence of the permeability of iron upon the intensity of the magnetic

field applied to it. Upon the same core of finely laminated iron there is a winding to carry high-frequency current and one for the microphone current. The microphone current as it varies takes the iron to different magnetic states, alters the permeability accordingly, and therefore varies the self-inductance of the high-frequency coils. Many matters of detail have had to be worked out in perfecting the apparatus; an important one

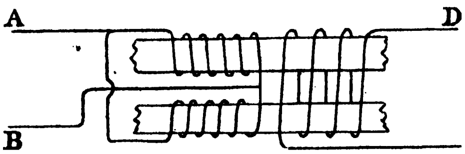

FIG. 3.

may be explained by aid of Fig. 3. Here A, B are the terminals of the high-frequency circuit, and C, D those of the direct-current or microphone circuit. The iron core seen in the figure is part of a closed magnetic circuit; it is in two portions, each of which carries half of the high-frequency winding; the microphone winding encircles both portions of the core. Since the high-frequency windings are wound to exert opposite magnetomotive forces on the halves of the core, they induce negligible high-frequency electromotive forces in the microphone coil.

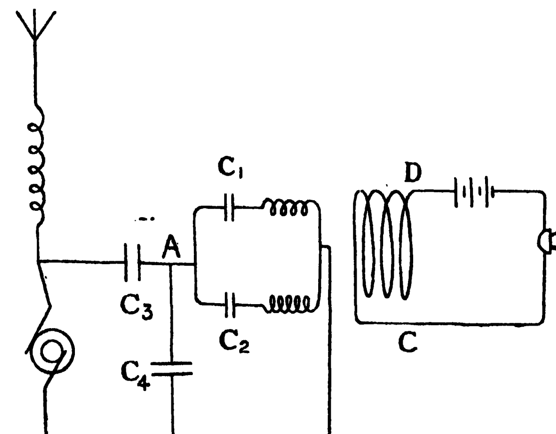

FIG. 4.

The connections of the apparatus to the alternator, the antenna, and the microphone are shown in Fig. 4, which also introduces further details, namely, the four condensers. For simplicity the windings are represented without their cores, though it must be remembered that the operation of the device depends entirely upon the magnetic properties of iron. The condensers C_1 and C_2 have as their chief function the prevention of the flow of undesired acoustic currents in the high-frequency windings. The condenser C_3 tends to annul some of the non-varying inductance in the circuit comprising the magnetic controller and the alternator, and the condenser C_4 appears to have been introduced for phase adjustment, and enhances the sensitiveness of the whole arrangement to changes of microphone current. The performance of the device is excellent; it is stated that a variation of 0·2 ampere in the direct current through the microphone has been made to alter the power given to the antenna from about 6 kw. to 43 kw.

It was by aid of this device that Ministers in Washington conversed with President Wilson in mid-Atlantic, the voice currents reaching the magnetic controller after passing over land wires from Washington to the New Brunswick wireless station. It will be noticed that in this method of varying an element of the complete antenna circuit the variation is not effected directly by the voice, and in this respect the method is unlike the former two methods.

A related class of methods of modulating the oscillations of the antenna is that in which a voice-varied mutual inductance is employed to transfer the high-frequency energy from the source to the antenna. Perhaps the nearest approach to such a method is that of Kühn, of the Telefunken Co. of Germany, though in his method the self-inductance of the circuits is varied also. The method has not worked out so successfully as that of Alexanderson, and need not be described here.

A third class of methods of modulation aims at varying the activity of the source of high-frequency current; this is in contrast with the preceding methods, in which the functioning of the source is not directly controlled. In the methods to be described the point of application of the control is, so to speak, behind the source, the antenna being supposed to be in front. For example, the direct current that creates the magnetic field of a high-frequency alternator, or the direct current or voltage supplied to one of the circuits of a triode oscillator—that is, an oscillatory circuit sustained in oscillation by means of a three-electrode vacuum valve—might be varied by the voice, and the high-frequency output to the antenna be varied accordingly. Many very miscellaneous schemes have been described; the difficulty is to make a representative selection. The triode oscillator especially lends itself to a multitude of ingenious designs.

In Fig. 5 the circuits of a simple form of oscillator are sketched. The coil marked L is connected at one end to the anode, at the other to the grid, of a triode, the filament being connected to a tapping in the coil. The inductance L of the coil and the electrical capacity C of the condenser constitute the circuit in which oscillations are to be maintained. The action of the circuits may be explained broadly thus: Suppose an oscillatory

current to be flowing in L and C, and that we choose an instant when the grid is, say, at a positive potential relative to the filament and rising in value; in accordance with the properties of these tubes the electromotive force transferred from the grid to the anode circuit of the tube will be from filament to anode outside the tube and rising in value. Thus the electromotive force acting on the portion of the coil in the anode circuit is in phase with the potential difference postulated to exist throughout the coil in virtue of the oscillating current in it, and therefore the electrical motion tends to be maintained.

In such an oscillator the frequency of the oscillations is mainly determined by the inductance and capacity, but every other circumstance of the circuits has its influence. Moreover, the amplitude of the oscillations often varies when the frequency does. Thus if acoustic variations be imposed upon the current employed for heating the filament, or upon the electromotive force in the anode circuit, or upon a source of electromotive force between grid and filament, the high-frequency output of the assemblage varies correspondingly. An ordinary microphone will, it need scarcely be said, be used for converting the voice-made air vibrations into current variations, and transformers will be used when of advantage for introducing the current variations into the various circuits mentioned above.

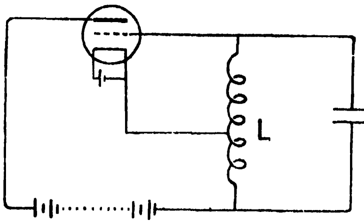

FIG. 5.

One of the most interesting of these methods was described by Major Prince in a paper read recently before the Wireless Section of the Institution of Electrical Engineers, the apparatus being that finally adopted by the R.A.F. for aeroplane work.

The principles employed may be seen from Fig. 6, which is drawn as free from detail as possible. The antenna A is maintained in oscillation by the transmitting triode R_1 in a manner similar to that of Fig. 5; the modulator tube R_2 magnifies the voltages applied to its grid by the microphone currents in the primary of the transformer T. The high voltage for the anode circuits of each tube is supplied by the battery E, which is in series with a large choking coil χ. When the microphone is quiescent the full voltage of E acts steadily on the anode of R_1, but when the microphone produces variable electromotive forces on the grid of R_2 these are multiplied, transferred to the anode circuit of R_2, and if the choking coil is large enough to be effective, and the condenser C not too large, they reach the anode circuit of R_1. In consequence the amplitude of the oscillations generated by R_1 is varied in correspondence with the microphone current variations, and to a small extent the frequency is changed also. This set of apparatus is styled a 20-watt set.

When the normal range of transmission must attain 100 miles, the problem of modulating the necessary power becomes formidable, chiefly on account of the limitations affecting the microphone. It is obvious that direct modulation by means of ordinary microphones is impossible except for small currents, say not exceeding 2 amperes; in consequence, in the endeavour to achieve long-range telephony, special microphones —some of them employing liquid conductors—have been devised, and sometimes many microphones have been used in parallel. At this stage the three-electrode vacuum valve comes to our assistance in various ways, some of which must now be explained. In the first place the triode may be employed as an amplifier of the variable currents or electromotive forces leaving the microphone, and these may be applied to the

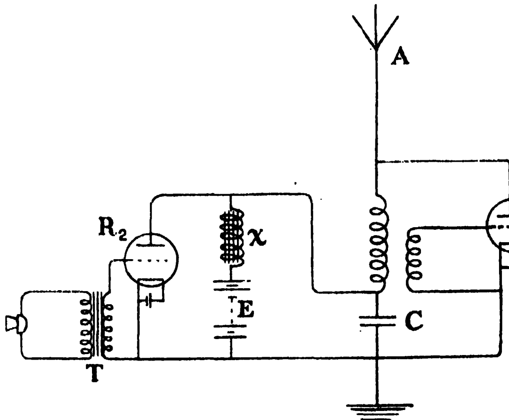

FIG. 6.

modulation of larger high-frequency currents than was before possible; the tube is then the actual modulator. An instance of this appears in Fig. 6. In the second place the triode may be utilised as a by-pass to deflect high-frequency current from the antenna to itself or to other apparatus capable of dissipating the necessary amount of energy—a subtraction method that has proved very successful. The tube may serve in either or both of these functions as modulator of the high-frequency current from arcs, alternators, or other sources of oscillations, not omitting the triode oscillator itself. Evidently the fact that these three-electrode valves can perform the distinct offices of generator of oscillations, magnifier of high and low frequencies, and modulator, and in each office may be associated with a remarkable variety of circuits, may be expected to lead, and is leading, to endless permutations and combinations in the circuits proposed for medium- and long-range wireless telephony.

There is space for brief descriptions of only two examples of large power plants. In 1914

the Western Electric Co. conducted a great experiment from the American naval station at Arlington, near Washington, and succeeded in speaking to the Eiffel Tower (3700 km.), and exceptionally to Honolulu (8000 km.). Triodes were used as oscillators, modulators, and magnifiers. The chain of apparatus was as follows: First came a triode oscillator of small power, which was coupled by means of a high-frequency transformer to the grid circuit of a medium-sized tube. This grid circuit contained also the secondary winding of a transformer, the primary of which carried the currents from the microphone. The anode circuit of this medium triode therefore contained magnified modulated current of the high frequency dictated by the small triode oscillator. The current was next transferred by means of a transformer from this anode circuit to the grid circuit of a bank of medium-sized amplifying tubes connected in parallel, and was again magnified, and finally it was transformed once more into a circuit containing the grids of more than 500 parallel connected tubes. It ought to be remarked that great progress has been made since 1914 in the manufacture of power bulbs, and that the experiment can now be carried out on a larger power scale with a far smaller array of tubes.

The remaining example to be cited is the recently erected 20-kw. plant of the Marconi Co. During the past few weeks it has transmitted good quality speech to a distance of 1500 miles. In principle it is of the subtraction or absorption type. A diagram of the chief parts appears in Fig. 7, from which are omitted all details regarding the heating currents for the filaments and concerning the rectifying of the high-voltage current for the anode circuits. The oscillations are generated in the circuit L C by a bank of six large three-electrode valves in parallel marked O_6, and transferred to the antenna by the coupling *k*. The absorption tubes are three in number, and are shown at A_3; their three anodes are large enough to dissipate all the energy normally given to the antenna. These absorption triodes are controlled by applying to their grids the speech electromotive forces after these have been magnified by the successive triodes M_1 and M_2. The total consumption of power is 20 kw., including all that necessary for heating the filaments, the height of the aerial is 400 ft., and the wave-length 2750 metres.

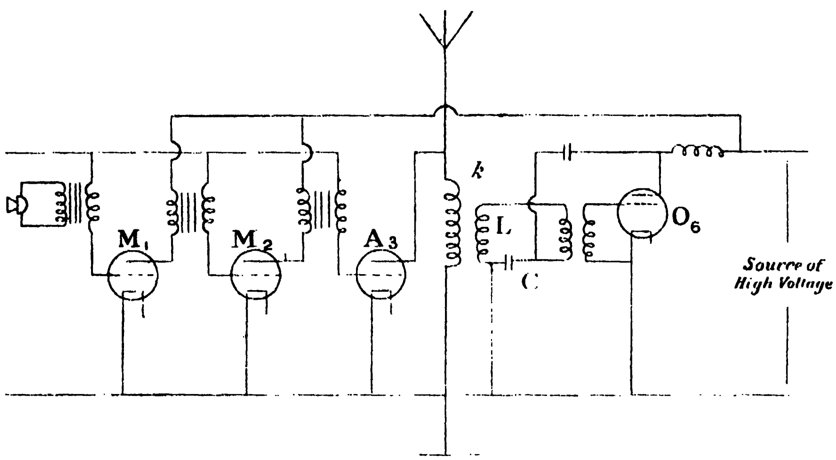

FIG. 7.

It will be noticed that the above are all one-way methods—that is to say, the two persons using two stations for conversation must speak in turn, and the listener must wait for the speaker to finish before he switches over from his listening circuit to his speaking circuit. This falls far short of perfection. For perfect telephony it is essential that both persons shall be able to speak and hear simultaneously if they so desire, as in ordinary line telephony. For information about the most modern attempts at duplex telephony a paper read recently before the Institution of Electrical Engineers by Mr. P. P. Eckersley should be consulted. Until a complete duplex method is devised and proved, wireless telephony must remain a somewhat irksome mode of communication for public use. The ideal method will be such that a wireless station on this side of the Atlantic could be connected over land lines to, say, London, and a station on the other side connected by land lines to New York, and the persons using the apparatus would be unable to tell that wireless telephony across the ocean had been an agency in the transmission of their voices.

The Meteorology of the Temperate Zone and the General Atmospheric Circulation.

By PROF. V. BJERKNES.

IN Norway, since the year 1918, an attempt has been made to base forecasts of weather on the application of a very close network of meteorological stations. The study of the corresponding very detailed synoptic charts has led to interesting results even for large-scale meteorology. These are due especially to three young meteorologists, J. Bjerknes, H. Solberg, and T. Bergeron, who have been attached to this service, and will return to the subject in detailed papers.

A very short summary of some of the main

results will be given here. These will be seen to give, to some extent, both verifications and further developments of ideas, which, although advanced by leading theoretical meteorologists, have not yet exerted any noticeable influence upon the development of meteorology.[1]

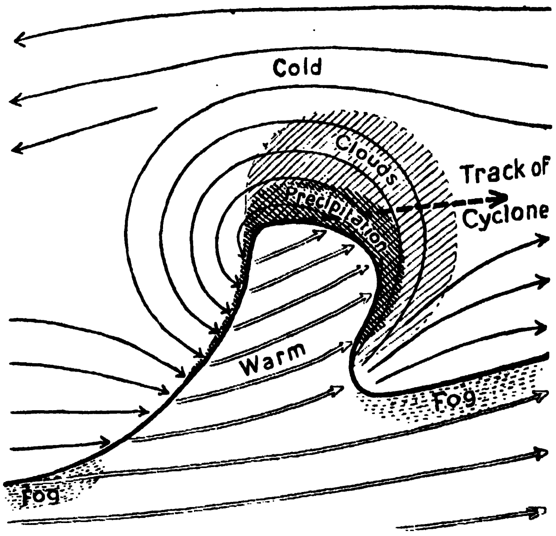

FIG. 1.—Cyclone.

Great changes in the weather in our latitudes have been found to depend upon the passage of a line of discontinuity which marks the frontier between masses of air of different origin. A line of this kind was first found to exist in every cyclone which is not perfectly stationary. It here borders a tongue of warm air, which from an east-bound current penetrates into a west-bound current of cold air (Fig. 1). The whole system moves with the east-bound current, and the cyclonic centre with the lowest pressure is in the region where the cyclonic track touches the border of the tongue. The front border, before this point, is curved like a reversed "S"; the rear border, behind this point, has a uniform concave curvature. Along the front border warm air from the tongue ascends the barrier formed by the cold air, which, in return, passes round the tongue in order to penetrate below the warm air along the rear border. Two bands of rain are thus formed —a broad one in front of the tongue, where the warm air spontaneously surmounts the cold, and a narrow one, generally called the squall line, along the rear border, where the advancing cold air violently lifts the warm air of the tongue.[2]

It has been found by use of the detailed maps that the line of discontinuity exists even outside the cyclone, passing from one cyclone to the other; they follow each other along a common line of discontinuity, like pearls on a string.

When one has become acquainted with all the signs—direct and indirect—which are seen to indicate the position of a line of discontinuity on the very detailed maps, it proves possible to discover them even on less detailed maps. Fig. 2 shows roughly the course of such a line, on January 1, 1907, as it may be drawn upon the Hoffmeyer maps of the Atlantic Ocean for that day. When similar charts are drawn from day to day, as accurately as circumstances allow, a series of large-scale results very distinctly presents itself.

Though we have been able to draw the line only half round the pole, there can be no doubt that it surrounds the polar regions as a closed circuit. On the northern side of this line all signs indicate air of polar origin; it has a low temperature for the latitude, shows great dryness, distinguishes itself by great visibility, and has a prevailing

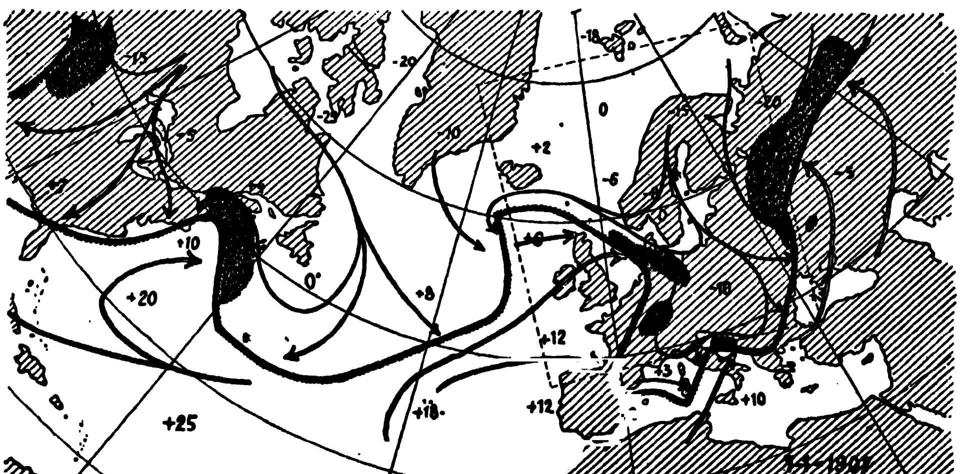

FIG. 2.—Line of demarcation between polar and equatorial air, January 1, 1907.

motion from east and north. On the southern side of the line the tropical origin of the air is recognised by the corresponding signs—its generally higher temperature, its greater humidity, its haziness, and its prevailing motion from west and south. There can then be no doubt concerning the origin of the line. Heavy, cold air flows out along the ground from the polar regions. It is separated from the overlying warmer air by a surface of discontinuity, the height of which above the ground decreases very slowly until it cuts the ground along our line of discontinuity. Thus this line shows how far the cold air has succeeded in penetrating; it is a kind of *polar front line*.

Along the whole of this front line we have the conditions, especially the contrasts, from which atmospheric events originate—the strongest winds, the most violent shifts of wind, and the greatest contrasts in temperature and humidity. Along the whole of the line formation of fog, clouds and precipitation is going on, fog prevailing where the line is stationary, clouds and precipitation where it is moving.

The line has a wavy form, and is in a continuous undulating motion, thereby sweeping over the whole of what is called the temperate zone. The wavy form comes from alternately cold and warm tongues of air, which extend themselves towards the equator or the pole. The whole system is moving from west to east, while the line, at the same time, changes its form, especially when great masses of accumulated cold air are expelled from the central polar regions. The more wavy the form of the line, the more tempestuous and variable is the weather. At the northern ends of the warm tongues the air motion which characterises cyclones is recognised, and the corresponding areas of rain are seen so far as it has been possible to mark them from the few observations; these are the places of great storms and low barometric pressure. The broad tongues of polar air, on the other hand, bring the clearing up between the successive storms and the corresponding higher barometric pressure.

Two expanding tongues of cold air may occasionally cut off from its base an interjacent tongue of warm air. Then the storm at the polar end is no longer supplied by warm air, and soon loses its power; this is the death of a cyclone. A tongue of polar air which has extended itself too much towards the tropics may be cut off in a similar way; or, as the consequence of a new outbreak of polar air, a more retired front may be formed behind one too far advanced. In this way great isolated isles of polar air are formed in lower latitudes; this gives the formation of great anticyclones, which generally bring settled, good weather. Thus anticyclones are born as cyclones die. Cyclone and anticyclone and all meteorological events of the temperate zone are in the most intimate way related to the polar front and its motion.

This expulsion of great masses of polar air, which leads to the formation of anticyclones, also enters as an essential element into the great atmospheric circulation. There is a practically continuous flow of warm air along the ground from the "highs" of the sub-tropic calms towards the polar regions. This flow concentrates itself in the warm tongues, and continues into the polar regions in upper levels. Here the air is cooled, and eventually reaches lower levels. Thus increasing masses of cooled air are accumulated behind the polar front. This must continuously advance, with the effect that the tracks of the corresponding cyclones are always moved further towards the south. Finally, at the place of least resistance, great masses of cold air break through and are expelled in the direction of the tropics. The polar front performs a corresponding retreat, the cyclonic tracks are again displaced to the north, and the type of weather is changed. Then the same action repeats itself. This intermittent form of the great atmospheric circulation is especially pronounced in the winter. During the summer the polar front is far back, and the high temperature of the continents exerts a considerable influence; then occasionally a continuous return of polar air may be established along the west coast of the continents, leading direct into the trade winds.

These results cannot fail to exert a considerable influence upon the methods of weather forecasting. All meteorological events of the temperate zone, great and small, are derived from the general atmospheric circulation described above, as we know it from the motions of the polar front. If we succeed in watching it effectively it should be possible not only to give short-range forecasts a hitherto unattained accuracy, but also to complete them by long-range forecasts giving the general character of the weather perhaps for weeks ahead. These two kinds of forecast could be extended to all regions of the temperate zone —oceanic as well as continental. The required survey of the polar front is merely a question of organisation.

The Cardiff Meeting of the British Association.

PREPARATIONS are going steadily forward in Cardiff for the forthcoming meeting of the British Association from Tuesday, August 24, to Saturday, August 28 inclusive. Owing to the crowded state of the town, the question of accommodation is causing difficulties, but these will, it is expected, be satisfactorily overcome. A list of hotels and lodgings will be issued at the end of the present week.

The Marquis of Bute has generously offered to give a garden party at the Castle on the Wednesday afternoon, and the invitation has been gratefully accepted by the Lord Mayor on behalf of the local executive committee. Owing to the

difficulties of transport, it has been necessary to give up the proposed reception by Lord Treowen on that afternoon, but it is hoped that arrangements can be made for a visit to be paid to Llanover in connection with one or more of the Saturday excursions.

A long list of works, factories, and other industrial undertakings has been compiled, some of which are sure to be of interest to the various members of the association.

Exhibitions will be a great feature of the meeting. The National Museum of Wales is arranging to display some of its treasures. There will be an exhibition of pictures and charts for school decoration arranged by a committee of the association in connection with the educational section. The botanical section is arranging a special exhibit, whilst collections illustrating the work of the various corresponding societies are being arranged in conjunction with the Cardiff Naturalists' Society.

A reception, specially intended for the members of Section I, will probably be given by Prof. J. Berry Haycraft in the new physiological laboratories of the medical school.

The list of foreign guests who have accepted the invitation to be present includes the names of MM. Bruno and Brioux, representing the French Department of Agriculture; Profs. Cayeux, Laplac, Fauvel, and Yves-Guyot, from France; Prof. Gilson, from Brussels; Profs. Chamberlin, Graham Lusk, and Kofoid, from the United States; Prof. Chodat, from Geneva; Profs. Hasselsbalch and Ostenfeld, from Denmark; and Don. G. J. de Osma, from Madrid.

Obituary.

PROF. J. R. RYDBERG, FOR.MEM.R.S.

PROF. J. R. RYDBERG, who died in December last after a long illness, made an enduring contribution to science by his investigations of the arrangement of lines in the spectra of the elements. Rydberg was one of the earliest workers on this subject, and he entered upon it with a full realisation of its significance in relation to the structure of atoms and molecules. His classical memoir, Recherches sur la Constitution des Spectres d'Emission des Eléments Chimiques," was presented to the Swedish Academy in 1889, but he appears to have arrived at his well-known general formula before the announcement by Balmer, in 1885, of the formula connecting the lines of hydrogen.

Notwithstanding the imperfect spectroscopic tables then at his disposal, Rydberg discovered most of the important properties of series spectra, including the relation between corresponding series in the spectra of related elements, and foreshadowed discoveries which were made later, when experimental work had sufficiently advanced. Some of the features noted by Rydberg were observed about the same time by Kayser and Runge, but his work had the special merit of connecting different series in the spectrum of the same element into one system, which could be represented by a set of simple formulæ having but few adjustable constants. He especially insisted that the hydrogen constant, now generally called the "Rydberg constant," should appear in the formulæ for all series, and, apart from slight variations from element to element suggested by the theoretical work of Bohr, nearly all subsequent attempts to improve the representation of series have involved this supposition, and have had Rydberg's formula as a basis.

Other valuable contributions to the subject were made by Rydberg, but the memoir above mentioned is the most comprehensive of his published papers; it is a perfect model of a scientific investigation, and may still be read with advantage by all students of physics.

Much attention was also given by him to the chemical and physical properties of the elements in relation to the periodic system, and in 1913 he published his suggestive memoir, "Untersuchungen über das System der Grundstoffe." His later work in this connection was seriously interrupted by ill-health.

Rydberg was born at Halmstad, in Sweden, on November 8, 1854, and entered the University of Lund in 1873. He obtained the doctor's degree in mathematics six years later, and after holding appointments in the departments of mathematics and physics, was appointed professor of physics in the University in 1901. About a month before his death he had retired from his professorship on reaching the age-limit of sixty-five years. He was elected a foreign member of the Royal Society in 1919.

THE death is announced of PROF. A. A. INOSTRANSEFF, who was for many years professor of geology in the University of Petrograd. Inostranseff was born in 1843, and began his geological researches in Germany, where he was led to devote special attention to petrology. His first paper, on the microscopic structure of some Vesuvian lava, was published at Halle in 1872. On his return to Russia he made important observations on the opaque minerals in crystalline rocks and on the metamorphic rocks of the Government of Olenez. He also did much geological surveying in the Caucasus in connection with projected railways. His interests gradually widened, and in 1882 he published a volume (unfortunately in the Russian language) on man in the Stone Age round Lake Ladoga. He had much success as a teacher, and among other researches which he encouraged may be particularly mentioned those of his pupil, the late Prof. Amalitsky, on the Permian deposits of northern Russia. The Permian theriodont reptile Inostransevia commemorates his name.

WE regret to announce the death, on June 19, of Dr. F. A. Tarleton, senior fellow of Trinity College, Dublin, a former professor of natural philosophy, and president in 1906 of the Royal Irish Academy.

Notes.

BY the gracious command of the King, the Society of Tropical Medicine and Hygiene, which was founded in June, 1907, will henceforth be known as "The Royal Society of Tropical Medicine and Hygiene."

WE recorded last week that at the anniversary meeting of the Linnean Society on May 27 the gold medal of the society was handed by the president to Sir Ray Lankester, to whom it had been awarded by the president and council. The president's anniversary address was devoted to an account of our present knowledge of the earliest known fossil fishes—the Ostracoderma—in the investigation of which Sir Ray Lankester was a pioneer, his monograph on Cephalaspis and Pteraspis having been published by the Palæontographical Society in 1870.

THE first gold medal ever given by the Institution of Sanitary Engineers was presented at the annual summer meeting of the institution last week to Major A. J. Martin "for his services in originating Health Week and in the development of civil and military sanitation before and during the war."

MR. MARCONI, who has just returned from Italy by sea, has favoured us with the following appreciative reference to the late Prof. Righi:—"Although I never had, as is often stated, the privilege of being a pupil of Prof. Righi, I have always had, as is well known, a very deep admiration for him and for his great and far-reaching work in connection with physics, and particularly electric waves. Prof. Righi, whom I knew well personally, was a man of singularly unassuming character, and by his death not only has Italy lost one of her foremost scientific men, but the world also loses a brilliant and original worker in the field of electrotechnics."

DR. F. G. COTTRELL, Director of the U.S. Bureau of Mines, has been awarded the Willard Gibbs medal of the Chicago Section of the American Chemical Society.

THE annual summer meeting of the Anatomical Society of Great Britain and Ireland is to be held at Cambridge on July 2 and 3. Papers on the morphology and development of the central nervous system have been promised, and there will be discussions on the structure of the earliest land vertebrates, the partial transposition of the mesogastric viscera, and avian structure as bearing upon problems of bird migration.

WE are informed by the Secretary of the Department of Scientific and Industrial Research that the Research Association for the British Motor Cycle and Cycle Car Industry has been approved by the Department as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. As the association is to be registered as a non-profit-sharing company, the promoters have applied to the Board of Trade for the issue of a licence under Section 20 of the Companies (Consolidation) Act of 1908. The secretary of the committee engaged in the establishment of this association is Major H. R. Watling, "The Towers," Warwick Road, Coventry.

AT the eighty-sixth annual general meeting of the Royal Statistical Society, held on June 15, the following elections took place:—*President:* Sir R. Henry Rew. *Treasurer:* Mr. R. Holland-Martin. *Honorary Secretaries:* Mr. A. W. Flux, Mr. M. Greenwood, and Sir J. C. Stamp. *Honorary Foreign Secretary:* Mr. R. Dudfield. *Council:* Mr. W. M. Acworth, Dr. J. Bonar, Dr. A. L. Bowley, Miss Clara E. Collet, Major L. Darwin, Mr. G. Drage, Mr. R. Dudfield, Mr. A. W. Flux, Sir D. Drummond Fraser, Mr. J. H. Gorvin, Mr. M. Greenwood, Sir Robert Hadfield, Bart., Sir Edgar J. Harper, Mr. R. G. Hawtrey, Sir H. E. Haward, Mr. R. Holland-Martin, Dr. L. Isserlis, the Right Hon. F. Huth Jackson, Mr. A. W. W. King, Mr. H. W. Macrosty, Mr. E. R. P. Moon, Sir Shirley F. Murphy, Mr. H. V. Reade, Mr. C. P. Sanger, Dr. E. C. Snow, Mr. J. C. Spensley, Sir J. C. Stamp, Sir A. D. Steel-Maitland, Bart., Mr. T. H. C. Stevenson, and Mr. H. Withers. It was announced that the Guy medal in gold had been awarded to Dr. T. H. C. Stevenson.

MR. JULIAN BAKER has been re-elected chairman of the London Section of the Society of Chemical Industry, and Dr. Monier Williams is to take the place of Dr. S. Miall as honorary secretary, Dr. Miall having resigned the position. The new members of the committee are Mr. A. Chaston Chapman, Mr. J. Conner, Mr. A. H. Dewar, Dr. B. Dyer, and Prof. W. R. E. Hodgkinson.

THE U.S. National Research Council, a co-operative organisation of leading scientific and technical men of the country for the promotion of scientific research and the application and dissemination of scientific knowledge for the benefit of the national welfare, has elected the following officers for the year beginning July 1:—*Chairman:* H. A. Bumstead, professor of physics and director of the Sloane Physical Laboratory, Yale University. *First Vice-Chairman:* C. D. Walcott, president of the National Academy of Sciences and secretary of the Smithsonian Institution. *Second Vice-Chairman:* Gano Dunn, president of the J. G. White Engineering Corporation, New York. *Third Vice-Chairman:* R. A. Millikan, professor of physics, University of Chicago. *Permanent Secretary:* Vernon Kellogg, professor of biology, Stanford University. *Treasurer:* F. L. Ransome, treasurer of the National Academy of Sciences. The Council was organised in 1916 under the auspices of the National Academy of Sciences to mobilise the scientific resources of America for work on war problems, and re-organised in 1918 by an executive order of the President on a permanent peace-time basis. Although co-operating with various Government scientific bureaux, it is not controlled or supported by the Government. It has recently received an endowment of five million dollars from the Carnegie Corporation, part of which is to be expended for the erection of a suitable building in Washington for the joint use of the Council and the National Academy of Sciences. Other gifts have been made to it for the carrying out of specific scientific researches under its direction.

DR. R. S. MORRELL has been elected president of the Oil and Colour Chemists' Association in succession to Dr. F. Mollwo Perkin.

DR. V. H. MANNING, lately director of the U.S. Bureau of Mines, has been appointed director of research in the American Petroleum Institute.

DR. J. R. ANGELL, chairman of the U.S. National Research Council and professor of psychology in the University of Chicago, has been elected president of the Carnegie Corporation of New York.

MR. E. C. R. ARMSTRONG describes in the June issue of *Man* an interesting acquisition by the Royal Irish Academy of two penannular rings with cup-shaped ends, two bracelets, and an elaborately decorated disc—all of gold—found last year in a bog in Co. Cavan. The gold disc is of special value. The ornamentation, which was probably made by pressing the gold plate into a bronze matrix, is so fine that it is scarcely going too far to describe it as the most delicately decorated gold object belonging to the Bronze age that has up to the present been acquired by the Irish National Collection. The use of these discs has been a matter of doubt, but we have a parallel in a bronze specimen found at Trundholm Moss, in the north of Zeeland, and another of Irish origin in the British Museum. The ornamentation is probably connected with sun worship, but the Cavan discovery is of additional importance in that now for the first time a gold disc has been found in Ireland associated with objects, such as the gold rings and bracelets, which can be dated in the later portion of the Bronze age.

IN the same journal Mr. J. Reid Moir describes the discovery of an early Neolithic "floor" in the neighbourhood of Ipswich. On the surface of the gravel underlying a stratum of peat a flint implement of grey material, not rolled or patinated, representing a well-recognised type of an early Neolithic axe of the chipped and polished variety, was unearthed. In association with this, flakes, apparently of the Mousterian order, almost certainly more ancient than the Neolithic axe, were discovered. The mammalian bones associated with the "find" were examined by Prof. Arthur Keith, who identifies two varieties of the horse, large and small, of oxen, red deer, a wolf or large dog, pigs, and sheep. The horse-bones had been smashed up, apparently for the extraction of marrow.

IN *Sudan Notes and Records* (vol. iii., No. 2, April, 1920) the Rev. D. S. Oyler describes the Shilluks' belief in medicine men. They undergo a rite of initiation. A fact of interest connected with them is that "many of the medicine men have physical defects, their children are usually rickety, and many of them are deformed. The natives say that this is caused by the fact that the shades of his victims bring a curse on the medicine man, and also on his family." Few Shilluks will admit that they believe in his powers, but they seek him constantly, and their whole manner of life is influenced by the witch doctor. "So long as the Shilluks are dominated by the medicine men they will make very slight advancement in their mode of thought and their manner of living."

THE twenty-sixth Report of the Danish Biological Station to the Board of Agriculture (Copenhagen, 1919) contains two valuable memoirs. The first, by Mr. P. Boysen Jensen ("Valuation of the Limfjord, I.: Studies on the Fish-food in the Limfjord, 1909–1917"), summarises the work of several years based on valuations of the bottom invertebrate fauna with its special significance as fish-food. The study of the amount of food present in each year, its variation, rate of growth, and connection with the plaice fishery, shows interesting results. The fauna varies from year to year in both amount and kind, and the breeding seasons of the most important species differ, some breeding yearly, others apparently only once in several years. A careful comparison of the annual production and consumption shows that in certain areas the food is not sufficient to support an unlimited transplantation of plaice, and that the years which were specially bad for fishing were those in which there was an unusually small amount of food available. Prof. C. G. J. Petersen, in the second memoir ("Our Gobies (Gobiidæ) from the Egg to the Adult Stages"), adds much to our knowledge of the young stages of these little fishes, so numerous in our seas and so difficult to identify in their early life. We note with satisfaction that he finally allows the specific value of *Gobius minutus* and *G. microps*, hitherto usually regarded as distinct forms of one species, and shows that they can be distinguished throughout their life by skeletal features and by pigment. The very beautiful plates, both coloured and plain, illustrating the various stages in the life-history of the Danish gobies add much to the value of this work.

IN part iii. of their remarkable series of memoirs on Old Red Sandstone plants from the Rhynie chert-bed of Aberdeenshire (not younger than Middle Devonian) Dr. Kidston and Prof. Lang give a full and abundantly illustrated account of a third generic type, *Asteroxylon Mackiei*, of vascular Cryptogams discovered by Dr. Mackie, who figured a single transverse section of the stem. Like Rhynia and Hornea, Asteroxylon was a terrestrial plant which grew in a peaty soil. The subterranean portion of the plant consisted of slender rhizomes, 1–6 mm. in diameter, without absorbent hairs, having a broad cortex differentiated into an outer and an inner zone, and a simple vascular strand of spiral tracheids surrounded by a cylinder of phloëm. Branches of the rhizome passed through a transitional region characterised by the presence of scale-leaves into aerial foliage shoots 1 cm. to 1 mm. in diameter, bearing numerous spirally disposed small leaves; and it is probable that certain slender leafless branches occasionally associated with them represent fertile shoots which bore pear-shaped terminal sporangia without an annulus, and dehiscing at the broad free end. No actual connection between the leafless axes and sporangia or between either and the shoots of Asteroxylon has been demonstrated, but there is little doubt that they were parts of one plant. The vascular cylinder of the

leafy shoots had a stellate stele, and from the enlarged ends of the arms small concentric leaf-traces were given off, which passed to the base of each leaf but never entered the free lamina. In habit Asteroxylon agrees closely with the well-known older Devonian plant, *Psilophyton princeps*, and to a rather less extent with Psilotum. It throws light on the morphology of certain Devonian plants known only as impressions, and raises many questions of theoretical interest which are discussed by the authors.

NEW light on several problems of Arabian geography has resulted from the war. In the *Geographical Journal* for June (vol. lv., No. 6) Dr. D. G. Hogarth deals with certain discoveries in the Hejaz. It has now been found that the watershed between drainage west to the Red Sea and north-east to the Persian Gulf lies further east than was previously supposed. Its exact course has still to be traced, but it certainly lies some distance back from the coast and runs through the Kheibar *harra* east of the Hejaz railway. Further south in Asir it comes nearer the Red Sea. Much material has been collected for the mapping of the Hejaz, especially in the north, against the Gulf of Akaba, and further south between Wejh and Rabugh. The intervening block, except for the littoral, is most imperfectly known. Considerable additions have also been made to our knowledge of the coast-line between Akaba and Aden. Dr. Hogarth concludes his paper by summarising some new information about Medina, of which a Turkish plan and several photographs have now been obtained. A British aeroplane which flew over the city secured a photograph of the railway station and immediate surroundings, but strict injunctions were given not to photograph the Haram or Great Mosque which contains the Tomb of the Prophet. The photograph secured on this occasion is reproduced, among others, with the paper.

THERE seems now to be evidence that so far back as the beginning of the Cambrian period conditions in the sea round the South Pole were not very favourable to life. In a piece of Lower Cambrian limestone dredged by the Scottish Antarctic Expedition from the bed of the Weddell Sea, and in other fragments of the same rock from the moraine of the Beardmore glacier on the opposite side of the South Pole, numerous remains of the sponge-like Archæocyathinæ have been found closely similar to those discovered in a corresponding formation in South Australia. All the Antarctic forms, however, are comparatively dwarfed, and show various thickenings and irregular additions to the skeleton which denote a struggle with adverse conditions. The specimens are described in great detail, with excellent illustrations, by Dr. W. T. Gordon in the Transactions of the Royal Society of Edinburgh (vol. lii., part iv.), but they do not throw any new light on the affinities of these remarkable fossils. They are associated with ordinary spicules of sponges, fragments of shells and trilobites, and a considerable growth of calcareous algæ.

THE *Museums Journal* for June welcomes the chance of increased co-operation between the University and the British Museum that would be afforded by the new site offered to London University, but points out that concentration is not altogether to the advantage of students arriving from the various residential districts, and that concentration in a restricted area will check the inevitable expansion of both University and Museum. This enforces, from another aspect, the argument put forward by Sir E. Sharpey Schafer in NATURE for June 17.

THE advances made in wireless telegraphy and telephony during the war were enormous, and in all the three fighting Services it has established itself as indispensable. A large section of the Signals experimental establishment at Woolwich is now devoted to the development of equipment to meet the requirements of the Army, which differ in several respects from those of the Navy or Air Force. Much of the apparatus has to be specially compact and mobile, and for the circumstances of modern warfare the quantity of messages to be dealt with in a short time renders high speed of transmission essential. The adaptation of the Wheatstone automatic transmitter, working from a previously punched paper strip, to wireless working enables speeds of transmission from 450 to even 1000 words per minute to be attained. The small currents through the contacts which are sufficient for wireless apparatus render the conditions particularly favourable for high speeds. Particular attention is given to the linking-up of line with wireless systems. High-speed messages come in over the wire in the ordinary way, and are automatically handed over to the wireless apparatus without loss of time in retransmission. Another recent development of wireless working, finding particularly useful application in the Army, is direction-finding, and very compact sets for this purpose with a range up to 250 miles are now being standardised at Woolwich. A point to which special experiment is being directed is the obtaining of a high degree of selectivity by which extraneous waves from near and far can be "tuned out" and the feeblest messages of the required frequency amplified to the extent necessary for satisfactory reception.

THE Deutsche Seewarte is resuming its activity in the direction of publications. We have received a report for the five years 1914–18, thirty-seventh to forty-first year of the institution, and with it an overdue report published in 1914 of a survey voyage of S.M.S. *Möwe* in 1911 to the West Coast of Africa. The course was from Wilhelmshaven to Ferrol, Cadiz, Teneriffe, Dakar, Freetown, Lome, Lagos, Lome, Accra, Lome, Duala, Banana, Boma, Swakopmund, and Lüderitzbucht, the last being reached on October 7, 1911. The expedition went up the Congo as far as Boma. Observations were taken of the depth of the sea and of the currents, temperature, density, and salinity at different depths down to 2000 metres. This oceanography, divided into the three sections, North-West, Equatorial, and South-West Africa, was directed by Drs. G. Schott and B. Schultz. A meteorological log was kept by Dr. P. Perlewitz, including some kite observations. The regular observations were taken at intervals of four hours, whether in harbour or on voyage, and the elements tabulated, in addition to the latitude and longitude, are direction and force of the wind, barometer,

dry- and wet-bulb temperature, relative humidity, cloudiness, sea-surface temperature, strength of current, and rainfall, with notes of any unusual phenomena, including the appearance of albatrosses and schools of dolphins or flying-fish. The charts included with the publication show the salinity and temperature in depth sections, the one for Mogador giving salinity, temperature, and density separately. The salinity seems to decrease southwards, and also generally with increasing depth.

THE March number of *Terrestrial Magnetism and Atmospheric Electricity* contains a summary, by Mr. J. P. Ault, of the results of the magnetic survey of the Atlantic made by the *Carnegie* during her voyage from Washington to Dakar, West Africa, and Buenos Aires during the autumn and winter. While the values found for the magnetic dip differ often by two or three degrees from those given in the last Admiralty Charts 3598, 3603, and 3775, the values of the observed deviation of the compass to the west differ by more than a few tenths of a degree from the charted values in certain limited regions only. Thus in the region between the Gold Coast and the Island of Ascension the Admiralty Chart gives the deviation to the west about one degree too large, and between Trinidad and Buenos Aires there is a considerable area in which the deviation is given too small by the same amount.

OWING to the decrease in research at Harvard during the war, vol. xiii. of Contributions from the Jefferson Physical Laboratory covers the three years 1916–7–8, and at least a third of the volume is devoted to Dr. P. W. Bridgman's work on the effects of pressure on the electrical resistance and thermo-electric properties of more than twenty metals. The pressures used reach 12,000 kilograms per sq. cm., and the temperature ranges between 0° C. and 100° C. With the exception of wires of bismuth and antimony, the resistances of metallic wires subjected to hydrostatic pressure decrease with the pressure, following a linear law approximately, and at 10,000 kilograms per sq. cm. have values about 99 per cent. of their values at atmospheric pressure in the case of cobalt and tungsten down to about 90 per cent. in the case of lead, tin, and cadmium. The temperature-coefficient of resistance remains almost unchanged. The effect of pressure on the thermo-electric properties is much more variable. The normal effect is to increase the thermo-electric power of the metal, but in three out of the twenty metals tried this is not the case. In most cases both the Peltier and the Kelvin effects are increased, but there are many exceptions. The author considers that the electron theory is quite incapable of explaining these results.

WE have received from Messrs. C. Baker, High Holborn, W.C., their classified list (No. 69) of second-hand scientific instruments. The list includes microscopes and accessories, telescopes and field-glasses, spectroscopes, surveying, astronomical, projection and physical apparatus, and contains particulars of more than 2000 pieces of apparatus. In these days of high prices intending purchasers would be well advised in the first place to consult Messrs. Baker's catalogue.

Our Astronomical Column.

MERCURY AN EVENING STAR.—The greatest elongation of Mercury (E. 25° 41′) occurs on June 29. On June 24 the planet will set at 9.54 G.M.T., or 1h. 34m. after the sun, and may possibly be detected close to the W.N.W. horizon by anyone with a good eye. A field-glass should render the planet distinctly visible about an hour after sunset.

THE ZEEMAN EFFECT IN FURNACE SPECTRA.—In continuation of his well-known researches on furnace spectra, Mr. A. S. King has recently been investigating the Zeeman effect for iron and vanadium in the electric furnace. Observations of the effect of a magnetic field on spectra have up to the present been chiefly confined to spark spectra, so that it is interesting to compare the effects when different sources are used. The electric furnace possesses, in addition, certain advantages over spark spectra for this purpose, since most of the low temperature lines are much more readily examined. Also, the inverse effect for absorption spectra is easily obtained by introducing a graphite plug to give a background of continuous spectrum. A description of the apparatus and results is given in the *Astrophysical Journal* for March. The furnace tube was placed parallel to the lines of force in a field varying from 6500 gauss in the centre to 9000 gauss near the ends, and observations were made of one hundred iron lines and ninety vanadium lines. The results of these preliminary observations seem to show that the effect is independent of the source used, since the observed separations agree both in character and magnitude with those of corresponding spark lines.

THE LUNAR PARALLAX AND RELATED CONSTANTS.—There is a set of quantities (the radius and figure of the earth, the intensity of gravity, the moon's parallax and the motion of her perigee and node) which are so intimately related that an alteration in one compels corresponding alterations throughout. Prof. W. de Sitter has endeavoured to obtain a mutually consistent series of values, and gives the results in vol. xvii. of the Proc. of the Royal Academy of Science, Amsterdam. It is impossible in a brief note to do more than give his conclusions.

Mean radius of earth—*i.e.* radius in geogr. lat. the sine of which is $\{\frac{1}{3}\}^{\frac{1}{2}}=6{,}371{,}237$ metres.

Value of gravity at that latitude (unaffected by centrifugal force), 9·82014.

π^1 = sine moon's parallax/sine $1''=3422{\cdot}544''$.

Compression of earth, 1/296·0.

Constant of precession, 50·250″; luni-solar precession, 50·373″. Mass of moon, 1/81·50

$\frac{C-A}{C}=0{\cdot}0032775$; where C, A are the principal moments of inertia of the earth.

Also, if A′, B′, C′ are the three principal moments of inertia for the moon, and

$$\frac{C'-B'}{A'},\ \beta=\frac{C'-A'}{B'},\ \gamma=\frac{B'-A'}{C'},$$

β is found to be 0·000626, and $f=\frac{\alpha}{\beta}=0{\cdot}92$.

This value of f is much larger than those previously found, which ranged from 0·49 to 0·75. In other words, the present paper makes the moon's equator less elongated towards the earth than previous determinations.

Prof. de Sitter's investigation reminds us of the late Prof. Harkness's "solar parallax and related constants." By a combination of all available evidence he deduced, nearly thirty years ago, a value of the solar parallax practically identical with that now accepted.

The Centenary of Sir Joseph Banks, Bart.

THE commemoration of the centenary of Sir Joseph Banks, Bart., who died on June 19, 1820, was celebrated by the Linnean Society on Thursday last, as mentioned on p. 496 of NATURE for June 17. After the usual formal business, Dr. B. Daydon Jackson read the first communication on "Banks as a Traveller," speaking of his four overseas voyages—first, the visit to Newfoundland in H.M.S. *Niger*, on board which his friend Constantine Phipps, afterwards Lord Mulgrave, was a lieutenant; next, the adventurous voyage of the *Endeavour*, Lieut. Cook commander, when Banks so amply proved his value in many untoward events; third, the voyage to Iceland; and fourth, his trip to Rotterdam in 1773, when he was still eager for an expedition to the North. The second paper, by Dr. A. B. Rendle, was entitled "Banks as a Patron of Science." Banks's life from his return to England in 1771 until its close in 1820 was that of an enthusiastic, liberal, and generally far-sighted patron of science. A friendship began with King George, which steadily increased, and Banks was consulted on important matters of very various kinds. He became botanical adviser to the King in relation to the Royal Gardens at Kew, which developed under Banks's guidance, becoming the repository of plants of economic and ornamental value from all parts of the world. Banks initiated or encouraged voyages of exploration, and kept up an extensive correspondence with men interested in science overseas. His house in Soho Square was the rendezvous of students and men of all classes interested in schemes of philanthropy or science; his magnificent library and herbarium were at the service of other workers, and after his death were bequeathed to the British Museum. For forty-two years he was president of the Royal Society. He was very closely, though indirectly, associated with the origin of the Linnean Society. Mr. James Britten, in the third paper, began by remarking that much of his paper was based upon the daily use of Banksian specimens for nearly half a century in the British Museum. The author showed that the popular belief that Banks left all his botanic work to his secretaries and curators, Solander and Dryander, was a mistaken one, and that Banks displayed great botanic acquirements.

The president remarked that official records of the British Museum testified to the active interest taken by Banks in all matters connected with its advancement, and that keepers and trustees alike referred to him for his advice and decision.

Certain objects closely connected with Banks were exhibited.

South-Eastern Union of Scientific Societies.

THE twenty-fifth annual congress of the Union was held at Eastbourne on June 2–6, under the presidency of Sir Edward Brabrook, who in his presidential address dealt with progress in anthropology and economics during the past quarter of a century. In regard to the latter, he expressed the opinion that the war seemed to have dismissed all economic orthodoxy into thin air, with unrestricted paper currency, reckless extravagance, trading by Government, and manipulation of markets, all of which had been borne with patience during war-time, but were intolerable in time of peace. Science had done what it could to provide sound instruction by the issue of standard works.

The second day's business began with a paper by Comdr. E. A. Martin on "The Glaciation of the South Downs," in which he endeavoured to show that the chalk hills received their final curving by ice-agency, and attributed much of the "clay-with-flints" deposits and the chalk rubble of the dry valleys to the agency of glaciers, having their rise on the Downs when they were at a greater height, with greater precipitation, and a low snow-line. He had mapped out the blocks of sandstones, ironstones, and sarsens, and concluded that short rivers could not have transported them to where they are now found. He compared the ironstones with similar deposits which have been found at Lenham, on the North Downs, to be of Pliocene age. He referred the rounded contours of the chalk hills to the grinding action of ice, resulting in their appearance now as huge *roches-moutonnées*. Striations were not, as a rule, found, because the rocks were such as would rather crumble and perish under the pressure necessary to produce them. One sarsen at Stanmer was found, however, distinctly to be striated. The author thought that there had been two clear periods of glaciation: one before the deposition of the temperate marine muds at Selsea, at the base of which were the famous Selsea erratics, referable to the glaciation at the close of the Acheulian period, and a later one which gave rise to the Rubble-Drift, after the development of the Mousterian culture. In a brief discussion which followed, the glaciation theory was opposed by Mr. T. Sheppard, of Hull.

Mr. C. C. Fagg read a paper on "First Steps in a Local Regional Survey," in continuation of the efforts which he has made for some years to stimulate the regional survey movement. Prof. Boulger, in the absence through illness of Miss G. Lister, read a paper on "The Eastern Extension of the Lusitanian Flora," with special reference to the locality.

Prof. E. B. Poulton delivered a public lecture on "Mimicry and Migrations of Insects," and this was attended by invitation by numerous boys' and girls' schools in the town. A paper was read by Mr. R. Adkin on "Migrations of Butterflies and Moths in regard to the British Islands." Mr. Adkin dealt with flights of migrating Lepidoptera and movements of larvæ by the agency of the wind, and discussed the question of whether such occurrences are to be considered as chance happenings or as the result of voluntary action on the part of the migrants. Some account was given of observed immigrations on the coast near Eastbourne, and further evidence was asked for. Mr. Adkin showed how the geographical position of the British Islands rendered them singularly suitable for the observation of such phenomena, and suggested the lines of movement by which such immigrants would be likely to reach our coasts. The paper was illustrated by maps and diagrams and by exhibits of the insects referred to.

The matter of the enclosing of so much of the Downs during the last year or two by barbed-wire fences was discussed, and a resolution was carried with much enthusiasm asking that joint steps should be taken by several influential bodies to carry through a scheme for the protection of rights of way over the Downs, and for the acquisition for public use of typical stretches of them.

A large collection of wild flowers was on exhibition during the congress. *Phyteuma spicatum* was said to be growing in large quantities in East Sussex this year, and orchids were found in profusion in and about Beachy Head. Excursions to Pevensey, Alfriston, East Dean, Old Eastbourne, and other places added interest to a very successful congress.

After one of the excursions the party returned to "Hodeslea" to tea. Huxley spent the later years of

his life in Eastbourne, and occupied "Hodeslea," which is now the residence of the Union's treasurer. The house was built by Huxley in 1890 and he lived there until 1895, whilst his widow remained there until her death in 1914. Mr. Adkin has recently placed a bronze tablet on the house relating these facts.

Genetic Segregation.[1]

By W. BATESON, F.R.S.

LATER developments of genetics have been, in the main, attempts to discover the nature and scope of *segregation*. Mendel proved that certain characters are determined by unit-factors. Their integrity is maintained by segregation, the capacity, namely, to separate unimpaired after combination with their opposites. We have been trying, first, to ascertain specifically what characters behave in this way, whether there is any limit to the scope of segregation or any classes of characters otherwise transmitted. Among characters known to be subject to segregation are illustrations of most of the features by which plants and animals are distinguished. In regard to two classes of characters the evidence for segregation is, nevertheless, rather noticeably imperfect. No quite clear proof exists that differences in number—*meristic* characters in the strict sense—are governed by factors comparable with those that control, for example, colour. The extra toe of the fowl and the single leaflet of the monophyllous strawberry are perhaps the best examples, but reservations may be entertained. Also, though segregation can be demonstrated in regard to *quantitative* characters, parental types thus distinguished often fail to re-appear, and the inheritance is subject to special complications.

Groups or complexes of factors are now recognised as sometimes segregating whole. Were it not that on occasion elements of the complex become independent, the group would pass for one unit-factor. The sex-complex is an obvious example. Intermediate flower-colours, like those of modern sweet peas, probably arise by this process. The plausible suggestion that the new terms are only rare cross-overs in a closely linked series does not fit the evidence. A striking illustration appears in Œnothera, in which, as Renner lately showed, several groups of characters normally segregate as single factors. These complexes are in several forms not borne equally by the two sexes of the plant, and most of them cannot exist in the homozygous state. By these discoveries the Œnothera problem is greatly elucidated.

The second question is to determine when in the life-cycles segregation can occur. Admittedly it is a phenomenon of cell-division. If we knew the animals only we might confidently adopt the view of Morgan that normal segregation happens during the maturation process at the stage of synapsis, when the maternal and paternal chromosomes are believed to conjugate in pairs. Most of the facts of linkage may be thus well represented, but the absence of crossing-over in the sex-heterozygote (Drosophila and silkworm) is not readily explicable, nor is there as yet extensive evidence that the number of linkage-systems agrees with that of the chromosomes—a primary postulate of Morgan's theory. The evidence for an orderly anastomosis, or even of any exchange of materials between chromosomes, is weak; and the visible features of chromosomes are scarcely suggestive of the prodigious heterogeneity requisite. Even if the linkage-systems correspond with the chromosomes, which is a most attractive conjecture, exchange of material between chromosomes need not be essential to crossing-over. It may be doubted, however, whether the general course of cytological evidence does not point to the *rôle* of the chromosomes being rather passive than active.

That in plants segregation even in its normal course is not limited to the reduction-division is now certain. In Matthiola, Campanula, Begonia, and Œnothera the genetic composition of the male and female organs may be normally different, and segregation cannot have happened later than the constitution of these organs. This kind of segregation must result in *Campanula carpatica* (experiments of C. Pellew) and in *Begonia Davisii* from the peculiar genetic properties of the female complex, for it re-appears in offspring derived from the female side for several generations at least, but not among those derived from the male side. Collins's evidence from Funaria proves further that sex-segregation may happen during the growth of a haploid form.

Periclinal chimæras and the production of distinct types from adventitious buds prove that segregation may take place during somatic development, whether in the differentiation of the layers or of the root. In the genetic properties of the tare-like rogues of peas there are features which not only illustrate the occurrence of gradational change in genetic properties, following somatic differentiation, but also show that this gradation affects the male and female organs differently. From these facts it must be concluded that normal and orderly segregation (apart from chance sporting) can occur at various cell-divisions, and not exclusively at reduction. Not impossibly these somatic segregations may be accompanied by some visible cytological differentiation, but that question must not be prejudged.

Having regard to the fundamental distinctions between the morphological relations of the germ-cells to the soma in animals and in the flowering plants, it is not surprising that the processes of segregation should be differently effected in these two groups of organisms.

[1] Abstract of the Croonian Lecture delivered before the Royal Society on June 17.

Colour Index of the British Isles.

AT a meeting of the Royal Anthropological Institute held on June 15, Prof. Arthur Keith, ex-president, in the chair, Prof. F. G. Parsons read a paper on "The Colour Index of the British Isles." He first reviewed the different ways of constructing an index of nigrescence, and directed attention to what he considered their weak points. Prof. Parsons proposed as a simple and workable index that the percentage in any group of individuals with dark brown and black hair should be added to the percentage with eyes in which any brown pigment is present, and the result divided by two. For practical purposes he found it better to record the percentages of dark hair and dark eyes separately. He then proceeded to examine the large mass of statistics collected by Dr. Beddoe in the middle of the last century, and pointed out that the first deduction was that women are in the mass darker than men, and that where the people are fairest the difference between the sexes is greatest, as the following table shows:

	No. of records	Index		Diff.
		Men	Women	
4 Northern Counties ...	1767	26·2	33·5	7·3
3 Eastern ,, ...	1563	34·4	38·2	3·8
2 Western ,, ...	4057	45·5	46·7	1·2

It therefore became necessary to exclude those

records of Beddoe in which the sexes had not been kept separate. Fortunately, however, nearly fifteen thousand records on males alone remained available. In the Northern and Eastern Counties, in the lowlands of Scotland, and again in Sussex and Hampshire, the correspondence of the tracks of the hair and eye indices was most marked, whilst in the Western and West-Central Counties, in Wales, and in the Highlands of Scotland the darkness of the hair was very much greater than that of the eyes. It was pointed out that those regions in which the hair and eyes correspond in lightness were historically regarded as the sites of the purest Nordic blood in these islands, while those parts in which the hair track was much higher than that of the eyes were the sites in which we have every reason to believe the Mediterranean blood had mixed most freely with the Nordic. Where the two races had mixed it appeared that the light Nordic eyes and the dark Mediterranean hair were the dominant factors. Except in Wales, a percentage of more than 50 dark eyes is unknown in the British Isles.

On comparing town and country dwellers it was noticed that the towns were darker than the country, except in those parts where the nigrescence was very high, when the reverse was the case. It was suggested that one reason for this might be that the town dwellers were more migratory than those of the country, though probably this did not account for all the difference

The distribution of red hair was worked out and found to be greatest in Scotland and the North of England, where the nigrescence was least. It was also pointed out that the evidence available showed that it was more prevalent among the upper than the lower classes, and that this probably coincided with a lower index of nigrescence in the upper than in the lower classes.

In opening the discussion, Prof. Keith said that Prof. Parsons's paper was of supreme importance to all who were interested in the origin of the peoples of this country. In his opinion, pigmentation was probably the key to the problem, and Prof. Parsons's new method of estimating nigrescence was a real contribution to the study of the subject. His index was, however, in a sense, an average, and must therefore be used with caution. In referring to the lack of correspondence between hair and eye colour, he instanced the dark hair found in conjunction with grey eyes in Wales, Ireland, and West Scotland—a conjunction also occurring in Scandinavia. After thirty years of observation, however, he himself was still in doubt as to the difference between a Celt and a Saxon, and felt it impossible to distinguish between individuals from, say, Suffolk and Connaught. In his view the basis of the population of these islands was predominantly Nordic.

Dr. Brownlea said that he considered the results based upon the distinction of sex were not quite trustworthy. He held that six distinct races went to make up the population of these islands, one of these being a distinct red-haired race.

Mr. H. Peake, while agreeing with Prof. Keith that averages were untrustworthy, said that Prof. Parsons's index was not quite an average, and in any case it was the best method of dealing with observations which had been advanced so far. The conjunction of dark hair and light eyes was a puzzle. Was it due to a tendency in the Mediterranean race towards light eyes, or was it due to a fusion between the Nordic and Mediterranean types? Certain characters seemed to follow sex, and in cases where there had been an immigrant male population intermarrying with the females of the country, the dominant character of the male reappeared in the male line. Prof. Parsons's results pointed to this, in that where there was a considerable Nordic influence there were wide sex differences; where Nordic influence was small there was little difference between the sexes. He pointed out that not all red-haired people were alike in shape and colour. It had been suggested that red was a variant of fair hair, *e.g.* in Scandinavia. The older theory was that it was a border-line colour between fair and black. In Ireland, Wales, and Scotland it might arise from a crossing of Nordic and Mediterranean types. On the other hand, in the North of England it might be a variant of fair hair, as in Scandinavia. But even Scandinavia, he pointed out, was not homogeneous; light and dark types occurred, and therefore in that country also red hair might be due to contact.

Dr. Shrubsall said that in his investigations of the incidence of dark hair in town populations he had found that the longer the town history of a family, the darker the hair. He pointed out that the occurrence of red hair in the March country of Ireland, Wales, and Scotland supported the view that it was due to contact of light and dark types.

Dr. Stannus said that while investigating albinism in Africa he had found a large number of red-haired individuals, but in these cases the pigment was always found in solution. The problem was biochemical, and, in his opinion, microscopical examination was essential to show whether individual cases were cases of black hair in which the pigment had not been thrown out in granular form.

The chairman, in bringing the meeting to a close after Prof. Parsons had briefly replied, said that the discussion had shown the desirability of a much wider survey of the people than had hitherto been made. The results would have an important bearing upon such questions as the relation between health and race. He hoped that the Government might be induced to help in this great undertaking.

Army Hygiene and its Lessons.[1]

By LT.-GEN. SIR THOMAS GOODWIN, K.C.B.

UNTIL quite recent years it has never been sufficiently recognised that a very large proportion of Army medical effort should be directed towards the prevention of disease. The fact that in all wars in the past more men died from disease than from enemy action appears to have been accepted more or less with resignation, and regarded as inevitable. During the later years of the nineteenth century the increasing advances in science and our more exact knowledge regarding the ætiology and transmission of infective diseases led many medical officers to attempt to create barriers against the spread of disease by known paths, but there was a lamentable lack of co-ordinated effort.

Towards the close of the eighteenth century we begin to glean something in the nature of figures regarding sickness in armies in the field. In 1792 the allied Austrian and Russian armies were in Champagne; they commenced their retreat on September 30, and by the end of October had evacuated France, and during that short month, without any considerable fighting, they lost 25,000 men, or more than one-fourth of their number, every village being filled with dead and dying.

Accurate figures are unobtainable regarding Napoleon's campaign in 1812, but we learn that in June, 1812, he crossed the Niemen with a magnificent army

1. From three Chadwick Lectures delivered on March 8, 15, and 2 entitled "Army Hygiene prior to the Recent War," "Army Hygiene during the Great War," and "Army Hygiene in the Future."

of 400,000 men; he reached Moscow on September 14, the retreat began on October 19, and on December 13 he recrossed the Niemen, and of his great army more than four-fifths had melted away.

Probably one of our most disastrous campaigns, from a hygienic point of view, was the Walcheren Expedition of 1809, where our mortality from disease amounted to 346·9 per thousand of strength of troops.

Regarding the Crimean campaign in 1854 I shall say but little; we have all read of the trials and hardships of the troops in that campaign, in which the mortality from disease amounted to 230 per thousand of the strength.

In the Afghanistan War of 1878–80 the mortality was 93·7 per thousand, which appeared to be an improvement compared with the terrible figures which we have just considered.

Bad as these figures are, yet those of other nations are even more unfavourable; for example, in the French Sudanese campaign of 1888–89 the mortality from disease amounted to 280 per thousand—worse figures than those of our own Army in the Crimean campaign thirty-five years previously.

I think that perhaps the most striking example of the havoc which may be wrought by disease on an army in the field is that furnished by the French Army in Madagascar in 1895, where the mortality from disease amounted to 300 per thousand of strength. In this campaign 7 men were killed by the enemy and 94 wounded, while the deaths from disease numbered 5600. The actual admissions for sickness amounted to more than 15,000, or 85 per cent. of the whole force.

The evils in the past were mainly due to lack of co-ordination and of real knowledge on which concerted action could be based. Nevertheless, advances were made, and, as an example of the steady, progressive improvement in the health conditions of the soldier and the increased success in disease prevention, it is interesting to note that in India during the five years 1878–82 the following were our sickness and mortality rates per thousand of men serving among European troops:

	Constantly sick	Deaths	Malaria	Dysentery	Cholera
1878–82	68·1	20·5	569	42·8	5·7 (4·2 deaths)

Compare these figures with those for 1912:

1912	28·8	4·6	82	5·2	0·3 (0·2 deaths)

As regards conditions in the civil community, probably the first really important step towards an improved condition of affairs in England dates from the passing of the Public Health Act in 1875. Two hundred years ago the annual death-rate in London was 80 per thousand; I think it is now about 18 per thousand.

Military hygiene differs little in theory from that relating to the public health of a civil community, and in times of peace is closely allied to that ordinarily carried out in all branches of the Public Health Services.

There are, however, certain considerable advantages in military hygiene which find no counterpart in civil life. The measures which the sanitary officer recommends, when accepted, are carried out with all the power of military organisation and discipline behind them, and insanitary conditions and disease are subject to a far greater control than can usually be obtained with a civil population; so that, before the South African War, great advances had been made in the status and training of the Medical Service generally, but there were still many defects, the chief of which were lack of organisation in the Sanitary Service, deficient education and training in hygiene of the officers and men of all branches of the Service, and lack of co-ordination between the Medical Service and the rest of the Army.

Now let us consider the South African War. From what I have said you will realise that we entered on that war fairly equipped with knowledge, but with a deficiency of organisation as regards the hygienic requirements of an army in the field. It is true that affairs improved very considerably during the course of the war, but the unpreparedness at the outset bore its inevitable harvest. During this campaign some 14,000 men died from disease as compared with about 7000 killed. As regards enteric fever, we had 57,684 cases with 8022 deaths. Dysentery alone accounted for 86 admissions per thousand of the strength, and from all diseases we suffered 843 admissions with 24 deaths per thousand of the strength; while wounds in action accounted for 48 admissions with slightly less than 3 deaths per thousand.

South Africa saw the dawn of the organised scientific study of disease as regards its actual incidence in the field. Much of the success achieved by field hygiene and sanitation in the recent war may be traced to experience gained in the war in South Africa.

The Army Medical Service emerged from the South African War convinced of the absolute necessity for improving the sanitary organisation on certain definite lines. It was, in fact, at last generally realised throughout the Army that in war nothing is so costly as disease. The main requirements were, first, the *education* of the troops themselves—officers, non-commissioned officers, and men—in the aims and methods of hygiene. The second necessity indicated was the allocation of certain officers and *personnel* for sanitary work alone, and for their special training, in addition to the continued training of all medical officers, in the very latest scientific work. The third, and perhaps the most important, requisite was *organisation for war*.

This organisation was so arranged as to compass a thorough sanitary control of the lines of communication in order to filter off unfit men suffering from contagious or infective disease, and at the same time to maintain a freedom from disease of all *personnel* passing through the various channels and fixed establishments comprising the lines of communication. In France, for example, during the past war, it may be said that, beyond an outbreak of dysentery at one training centre, clearly traced to an influx of "carriers" from the East, the lines of communication during the whole period were maintained almost free from outbreaks of epidemic disease of any serious or extensive nature.

How very different were the conditions under which the Army took the field in 1914 from those of former wars! The scientific investigations of the preceding years had stabilised to a very large extent the hygienic environment of the soldier. Careful work on his foodstuffs as regards quantity, variety, and quality assured him a sound basis on which to wage war.

Undoubtedly much of the low incidence of infectious diseases enjoyed by the troops in the field during the whole war was due to a high resistance maintained by the ample and excellent condition of the food-supply. In the same way the equipment, clothing, and personal hygiene of the troops had all been envisaged on the soundest lines; while the method and practice of sterilising water-supplies and safeguarding foodstuffs, as well as the disposal of waste products, had been carefully thought out and generally inculcated.

Now let us consider the three main essentials to life, namely, food, water, and air. The *food* of the troops and its intimate relation to that important organ

"on which" (we are informed by high authority) "the army marches" likewise gave cause for the most careful study and preparation. In the past the military ration had been arranged upon more or less empirical lines after actual test marches. During the war, however, the menace of a national shortage of food and the importance of avoiding waste led to more exact studies of the needs of the troops by a detailed assessment of their actual energy output by the method of indirect calorimetry. Simultaneously with these studies, the assessment of the needs of the civil population by the Royal Society (War) Committee furnished information of incalculable value both for the future and, indeed, for the present time of world shortage.

It was a matter of no little difficulty to provide the many varied rations required by different peoples in different theatres at differing seasons and under varied military conditions; but, speaking generally, the Army of eight and a half millions had throughout been fed in such a manner as to enable it to fight effectively, to provide the energy and heat required, and to avoid outbreaks of disease traceable to the diet, with the exception of minor outbreaks of neuritis and scorbutic cases in those most distant areas—Mesopotamia and North Russia. In these localities the difficulty of at once arranging for local produce in severe climatic extremes and the dependence on preserved supplies from home were accountable for the outbreaks in question. Steps were quickly taken, however, to provide the necessary accessory food factors, at first by germinating pulses and by yeast, later by the intensive cultivation locally of fresh foodstuffs—measures which proved of great value both to the native inhabitants and to the troops.

The question of *water-supply* is one of the first importance. During the few years before the war experimental work on the various physical and chemical means of sterilisation—or at least of purification—of water had been carried out in several directions. Just prior to the war dependence had largely been placed on the use of filter-candles, but they were found to be unsuitable for active service conditions, and were replaced in every case by chlorination. The net result of war experience was the undoubted value for sterilisation purposes of chloride of lime in the form of bleaching powder. This substance, as is generally known, contains from 30 to 33 per cent. of available chlorine, which in turn liberates nascent oxygen in water, and this is effectively lethal to micro-organisms. Chloride of lime was used throughout the war as the means of dealing with all water-supply, either in bulk, as in the big "water-points," or regimentally in water-carts, pakhals, or containers of different shapes and sizes. As the war proceeded the need for the provision to advancing troops of properly treated water in large quantities led to the development of special Water-tank Companies. These units—first recommended in France by our own sanitary advisers—are capable of collecting, filtering under pressure through sand, sterilising by chlorine gas (by means of an ingenious regulator), and transporting large quantities of water wherever the motor-lorry (which was their basis) could move. In the same way barges for use along the waterways of the various theatres of war were developed. As an example, it may be mentioned that the ordinary barge of Northern France would deal with—and deliver—5000 gallons of pure, sterile, and tasteless water per hour; any suggestion of flavour of chlorine was removed by a "dechlorinating" process with sulphur dioxide gas.

These new water units proved of immense value, and are effective against mineral poisons as well as against bacterial or protozoal contamination. To meet the varying requirements of the different waters utilised in, *e.g.*, France or Egypt or Murmansk, different amounts of "bleach" were needed. The estimation of the required quantity would have been a matter of some difficulty but for the provision of a special test in the form of the "Horrock's Test Case," the action of which is based on the known fact that, generally speaking, 1 part per million of free chlorine suffices to ensure bacterial sterilisation in water, and that before this amount of free chlorine is available a certain varying amount will be used up indirectly in the oxidation of organic matter and the ordinary non-pathogenic or saprophytic organisms. Similarly, in view of the possibility of mineral poisons, medical officers were supplied with test cases to detect arsenic and the other commoner metallic poisons. Of the detail of the water organisation there is barely time to speak here. It is perhaps enough to say that, despite the variety of the theatres of war and the possible contaminations in these various areas, there was no outbreak of those water-borne diseases which have been so destructive to armies in the past. In this connection it may be of interest to add that the success of water chlorination in the field led to its adoption in certain major schemes at Boulogne and Rouen, where, for example, we were enabled to undertake chlorination of the municipal water-supplies, and so satisfactory was this that laboratory tests showed the tap-water of Boulogne, drawn at random some few weeks after the scheme was initiated, to be absolutely sterile. It is interesting to note that the American Forces adopted a similar scheme in a number of the larger towns in France occupied by their troops with equally good results. It is necessary to say how much of the excellence of the water arrangements was due to the high technical skill of the Royal Engineers in their very difficult task of providing the huge quantities required. In many cases this necessitated the actual boring of wells and the pumping forward to large "water-points," even in some cases to the trenches, by means of rapidly laid pipe-lines. During the offensive in the summer of 1918 the Third Army advanced through a waterless zone having a frontage of 12 miles and a depth of 20 miles; water was obtained by means of 6-in. bore-holes sunk by the Royal Engineers in the chalk, which yielded 9000 gallons per hour. Altogether, 500,000 gallons were obtained daily from the bore-holes and distributed to the troops by the Water-tank Companies. This method was continued until the enemy's water system was available.

I would now briefly touch on the question of *air and ventilation*. At an early date after the Crimea it was recognised that "spacing out" of men in barracks was essential, and the Army Regulations were framed to give every man a space of 600 cub. ft., or, assuming a 10 ft. high room, 60 sq. ft. of floor-space. This very excellent decision was in itself sufficient to reduce markedly the sick-rate and death-rate from tubercular and other respiratory diseases; and, in view of latter-day knowledge, was a remarkable piece of foresight. One need scarcely recall Pflüger's experiments on droplet infection, and how he showed the range of such infection from mouth to mouth to be somewhere within 1½ metres—in other words, that that range should represent the minimum proximity of men's heads in barracks or beds. The importance of that knowledge had not, perhaps, been fully realised, or, at any rate, had been submerged by reason of national necessity. Two instances have, however, recently shown that the principle involved—now known as "spacing-out"—cannot be disregarded. These were (1) the cerebro-spinal meningitis outbreak, starting in

1915, and (2) the influenza outbreak of 1918. In both these instances a populace, largely non-immune, was unavoidably—by military and national necessities—concentrated, with a resultant reduction in the spacing-out, and an opportunity arose for "mouth-to-mouth" or "droplet" infection. It is scarcely necessary to say that the pressure of hygienic advice was sufficient to represent the needs of the problem in each case. In the cerebro-spinal meningitis outbreak immediate spacing-out of the affected troops produced a rapid fall in the case and "carrier" incidence; in the same way, strong representations as to the need for drastic reductions in the number of troops carried in confined areas, such as ships, or of the methods of slinging hammocks in respect of the head positions, were latterly effective in reducing the unfortunately high incidence of influenza on its last appearance as a pandemic.

It may be of interest to note that the experience of the war had led to a reconsideration, and still further enlargement, of the cubic space allowed the troops, particularly overseas; and also of the correlated questions of pharyngeal and pulmonary disinfection. The importance of the former point—pharyngeal disinfection—was early recognised, and all transports were provided with means for dealing with the *personnel* aboard in special inhalation chambers. It is intended that these shall be a permanent feature of transports in the future, and it is of interest in this connection to note the recent encouraging reports from industrial works of the value of certain gases, inhaled in insensible but definite amounts, in inhibiting the incidence of influenza and allied respiratory disorders.

So much, then, for questions affecting all the troops. Now we come to the more special problems affecting particular groups of soldiery, and perhaps the most important is the *control of outbreaks of infectious disease.*

Epidemic disease, with the exception of the influenza pandemic, was noticeably absent, and the care taken to filter off "unfits" on the lines of communication went far to explain the remarkable freedom from disease of the men in the line. In respect of the excremental diseases, with their evil record of morbidity in past wars, and particularly of Enterica, the problem was approached in two ways: First, by the general inoculation of the troops so as to provide a relatively high immunity, and, secondly, by the careful disposal of all infected matter—in other words, by good conservancy methods. Inoculation during the early part of the war was carried out with typhoid vaccine, and a very large proportion of the troops was protected in this way. Later, in 1915, a triple vaccine was used—"T.A.B."—while troops proceeding East were provided also with cholera vaccine.

The sanitary sections were chiefly responsible for the constructional, advisory, and inspectorial duties involved in providing fly-proof field latrines of the deep-pit type, food larders, and safes for units otherwise unprovided, for the continued and varying problems connected with the reduction of the fly population, and for the supervision of large water schemes. The fly question, especially in Eastern theatres, is a vast and difficult one in view of the quantity of horse-litter inevitably associated with the Army, and frequently of the tactical or climatic impossibility of burning such fertile breeding matter. The Army was fortunate in being able to utilise expert advice on the problems raised from prominent entomologists, and in having officers and men who set themselves enthusiastically to carry out the methods adopted or tested.

But while the more serious diseases were largely defeated, it was found that there was a very considerable wastage in all theatres of war from insect-borne diseases of different types. In France a very great deal of the minor sickness of the troops was traceable to louse infestation, either as the cause of various septic skin conditions or from trench fever, which was early recognised as a new clinical entity, and has now been clearly proved to be a louse-borne disease. This question of the infestation of troops with lice is one of the most difficult problems of the sanitary officer, particularly in the case of troops crowded together or living under unnatural trench conditions. To this question the energies of a very considerable *personnel* were directed, and to it all the support of the military authorities was lent. The sufferings of our Allies the Serbs, and since then of a majority of the population of Eastern Europe, from another louse-borne infection, typhus fever, also emphasised the necessity for a vigorous campaign of disinfestation. The problem was met largely by the simultaneous provision of facilities for bathing at intervals not exceeding a week or ten days, and by the increase in facilities for disinfecting personal clothing and blankets at one and the same time.

At this point it appears suitable to mention the development in methods of disinfection by steam. In the early days the troops in the field were dependent on the few box-disinfectors available, while the rear-ward units were supplied with Thresh disinfectors. With the provision of divisional sanitary sections, portable Thresh machines were also supplied to each division. It was soon apparent, however, that for the regular treatment of clothing required by the anti-louse campaign this was not sufficient. The ultimate development which resulted was the Foden-Thresh apparatus, comprising two large Thresh disinfecting chambers mounted on, and operated under slight pressure by, a Foden steam lorry. In this way the apparatus could be rapidly moved to any area in which it was required, at once commence operations by turning the steam into the chambers, and then be driven to a fresh centre for operations.

The disinfestation centres were of immense value, but were often inadequate to eradicate the louse plague entirely owing to the escape of certain individuals or articles. To meet the needs of men in such circumstances, general issues were made of certain repellent substances of proved value, but more reliance was placed on the regular treatment of clothing and blankets; and the experience gained in this connection will be of lasting value, for there has developed, as one profoundly valuable result, the use of hot air as a practical method of disinfestation—a method even simpler, cheaper, and more rapid than steam, and one destined, it is hoped and anticipated, to hold a permanent place in the larger schemes of control of insect infections of the future. It is of interest to note that flour-millers in Canada are now utilising this method for the destruction of moths in preference to the older and more dangerous "H.C.N." method. The latest "Orr hot-air huts" are models of efficient disinfectors. The subject, however, remains one for further study and co-operative methods of control. The problem to be met during the demobilisation of 20,000 men daily from France (and of smaller numbers from elsewhere), was no easy one, but of the utmost importance in order to avoid the dissemination of infective disease among the civil community. Careful personal inspection was, of course, required in every case, combined with bathing, disinfection, and the issue of fresh clothing, and this colossal undertaking was carried out to complete satisfaction at a series of stations—at base ports in France each capable of dealing with no fewer than

3000 men per day prior to their embarkation. The absence in the community at home of any noticeable incidence of trench, relapsing, or typhus fevers goes to show the justification of the claim to success of the sanitary officers and *personnel* concerned in these works.

There were other insect-borne infections to be guarded against in different parts of the world where the military situation required our troops to serve. In some of these cases hygienic control was necessarily subservient to military urgency, and outbreaks of sickness occurred, the more readily so, perhaps, in the light of the unprepared soil which our young troops offered on first entry into tropical and sub-tropical zones. There is not time to detail the various minor hygienic campaigns, but the vast amount of anti-malaria work carried on in the various overseas war zones justifies notice. Being carried out, often with most complete success, from the point of view of mosquito elimination, there were at the same time areas where enemy action almost entirely forbade active measures of drainage, canalisation, or oiling. Even in these circumstances, however, it was not uncommon for certain of our officers, accompanied by a guard of two or three men, to push out into No Man's Land to oil certain stagnant waters known to be mosquito-breeding places. As to the extent of work carried out in draining, ditching, filling-in, etc., exact figures are scarcely procurable, but in the aggregate the efforts made must rank among the major schemes of the world, and be of incalculable value both by the improvement made and as an example to the inhabitants of the various areas concerned—Egypt and Palestine, Macedonia, Lower Mesopotamia, etc. In addition, however, to these offensive measures, defensive action against malaria was generally and thoroughly carried out by means of the provision of quinine, of netting of different forms, of special clothing, gloves, head-nets, etc., and of repellent substances, as also by the treatment of infected natives and various schemes for the isolation and removal of infected men who would otherwise act as foci for fresh cases.

From another aspect altogether the sanitary sections rendered valuable service; I refer to the economies effected. These economies were both direct and indirect. In the latter category may be placed the saving effected by the adoption of destruction of excremental matter by unit incineration which otherwise had to be disposed of with considerable expense by contract removal. Even of greater interest, however, was the direct saving resulting from the adoption of improved sanitary technique. In this category may be mentioned, first of all, the saving of fat. One of the most difficult waste-matters to get rid of in a cleanly way is greasy water—wash-up water, kitchen swill, etc. In seeking for better methods of disposal of this sullage the special cold-water grease-trap was devised, and soon pointed the way to an obvious economy. By the careful collection of all such wash-up fat, and of the scrap-fat and bone-fat rendered in cookhouses, a bulk of crude fat was obtainable which proved of immense use in aiding the national resources. A campaign of fat-saving was first initiated by the sanitary sections, and later developed and organised by the Quartermaster-General's Department. It was so successful that many of the war zones were able to make all their own soap locally, and, furthermore, to send home many tons of fat for making glycerine, then so necessary for the manufacture of munitions. As an instance, the saving of an average battalion was some 60 lb. of fat per day at a time when fat fetched at least 40*l.* per ton.

Another very useful economy was the collection of the solder from the sealing of the myriad tins used as food-containers. Nothing could be more striking than the picture presented by an up-to-date unit destructor consuming in cleanly fashion all the waste matter from a large camp, and at the same time melting out from improvised receptacles streams of solder, which dripped into cold-water receivers, while the heat of the furnace was utilised to heat large tanks of water, of value both for ablution and for the various washing-up processes so constantly required.

During the war many scientific investigations were carried out, both at home and in the actual theatres of war, for the elucidation of disease and the determining of the best modes of prevention. In some cases this necessitated the investigation of certain diseases which were either unknown in former campaigns or had been little studied in the past. Very valuable aid was given by the labours of the Trench-fever Committees at home and in France, and also by the War Nephritis Committee and Medical Research Committee in France. It having been clearly established that trench fever is conveyed by the louse, and diagnosis having been made possible, a great impetus was given to general measures of personal hygiene in the field, and also to improvement in methods of bathing and disinfestation. Trench fever was made notifiable in consequence, and a very great improvement resulted from the increased attention to precautionary measures. At the termination of the war the diseases had greatly declined, and no infection was conveyed to England on demobilisation.

By the labours, in short, of the united profession, all doing that work which was required of them and which local authority considered most immediately necessary, the troops were served as few armies have ever before been served.

In France, for instance, in 1918, out of a mean strength of 1,250,000 men of all races, the typhoid admission rate amounted to only 0·2 per thousand per annum, whereas in the case of the war in South Africa the admission rate reached the high figure of 130 per thousand.

In the case of dysentery the total number of deaths from this disease in France during the whole war was fewer than 200. These figures in themselves are a sufficient and lasting tribute to that branch of the Army to which so many of our profession have belonged, and from which we hope they have taken something in exchange for the much they brought to it.

An inevitable result of the war has been the recognition by everyone engaged of the value of "preventive medicine." This has led, on one hand, to the definite recognition of the Sanitary Service in the Army as an organised department, and has aroused, on the other, an increased interest among thoughtful members of the civil community into their own state—an interest which provoked the demand for an organised national effort, and ultimately led to the formation of the Ministry of Health.

In summing up my views, I would say that, in my opinion, the future prosperity and success of our nation depend to an incalculable extent on the improvement of the physical and mental standard of all members of the community; it must not merely be—as I am afraid it has been to a considerable extent in the past—a case of the "survival of the fittest," but rather a perfection of every method by which mortality may be decreased, by which the production of "unfits" may be diminished, and by which the

standard of fitness as regards man, woman, and child may be raised.

To attain this result we must all work together. In the words of Pope:

> By mutual confidence and mutual aid
> Great deeds are done and great discoveries made.

University and Educational Intelligence.

CAMBRIDGE.—Dr. Adrian has been appointed University lecturer in physiology, and Mr. F. A. Potts, of Trinity Hall, has been appointed University lecturer in zoology.

The Harkness scholarship has been awarded to E. W. Ravenshear, of Clare, and the Frank Smart prizes in botany and zoology to R. E. Holthum, of St. John's, and G. T. Henderson, of Gonville and Caius, respectively.

A second *ad interim* grant of 30,000*l.* has been made by the Government to the University pending the result of the inquiries of the Royal Commission.

An important report has been made by the Local Examinations and Lectures Syndicate, urging an extension of the provision of both money and men for extra-mural teaching.

The Board of Agricultural Studies has received a donation of 1000*l.*, collected by Sir Arthur Shipley, for the provision of lectures on tropical agriculture for five years. Dr. C. A. Barber, of Christ's, late of the Imperial Department of Agriculture, West Indies, and of the Indian Agricultural Service, has been appointed lecturer in tropical agriculture for five years.

Miss B. A. Clough has been appointed principal of Newnham College in succession to Miss K. Stephen.

EDINBURGH.—The University Court has appointed Mr. E. P. Stebbing, lecturer in forestry, to the recently instituted chair of forestry. The Court has also appointed Mr. John Petrie Dunn, a former Bucher scholar of the University, who at the outbreak of the war was Vice-Principal of the Kiel Conservatoire, as a part-time lecturer in the department of music.

The late Dr. J. G. Bartholomew has bequeathed to the University the sum of 500*l.*, to be applied towards the foundation of a chair in geography.

LEEDS.—Dr. W. E. S. Turner has been appointed professor of glass technology, Mr. J. Husband professor of civil engineering, and Dr. Mellanby professor of pharmacology. Mr. R. E. Pleasance has been appointed demonstrator in pathology.

LIVERPOOL.—Dr. W. J. Dakin, professor of biology in the University of Western Australia, has been appointed to the Derby chair of zoology in succession to the late Prof. Leonard Doncaster. Dr. I. M. Heilbron, professor of organic chemistry at the Royal Technical College, Glasgow, has been appointed to the chair of organic chemistry.

OXFORD.—Dr. Benjamin Moore, of the Research Staff, Department of Applied Physiology, Medical Research Committee, has been appointed to the new chair of biochemistry. The Halley lecture is to be delivered by Prof. R. A. Sampson.

PROF. J. STRONG, of the University of Leeds, has been elected president of the Association of University Teachers for the ensuing year.

DR. W. N. HAWORTH has been appointed to the chair of organic chemistry at Armstrong College, Newcastle-upon-Tyne, in succession to Prof. S. Smiles.

DR. V. J. HARDING, associate-professor of biological and physiological chemistry at McGill University, has been appointed professor of pathological chemistry in the University of Toronto.

MR. J. W. SCOTT, lecturer in moral philosophy in the University of Glasgow, has been appointed professor of logic and philosophy in the University College of South Wales and Monmouthshire.

A SUMMER school of librarianship is to be held at Bristol from August 30 to September 11, under the auspices of the University of London School of Librarianship. Some twenty-five papers have been promised for delivery.

THE Report of the Librarian of Congress for the year ending June 30, 1919, shows that the work of the principal library in the United States was carried on with success during the war in spite of great difficulties. Members of the staff died in the war and others have not returned, or have resigned on finding more lucrative work elsewhere. The work has also been hindered by a general rise in prices. The number of printed books now in the library is about 2,700,000. The Library of Congress prints a card catalogue of its books, which is justly valued for its accuracy. By June 30, 1918, the number of different titles in this card-index was 789,000. The average stock of each card was 75 copies, making the total number of cards in stock 60,000,000. The number of subscribers to these cards is 2693, and the sale of cards for the year produced 73,000 dollars. A large number of Chinese books has recently been purchased. The Chinese section is a unique feature of the library, and now contains no fewer than 887 Chinese official geographical gazetteers. These gazetteers are of great value in the study of the industry, art, agriculture, and geography of China. The report invites executors or others who may possess manuscript papers relating to persons of national importance in politics, science, literature, or art to submit these papers for examination. The librarian undertakes to return papers of a strictly personal or family character, and to preserve any valuable material that might otherwise be lost or destroyed.

Societies and Academies.

LONDON.

Royal Society, June 10.—Sir J. J. Thomson, president, in the chair.—A. V. **Hill** and W. **Hartree**: The thermo-elastic properties of muscle. The employment of a thermopile in a carefully closed-in chamber, immersed in well-stirred water inside a double-walled vacuum flask, together with photographic registering of the galvanometer response, has made it possible to record the thermal consequences of stretching a muscle (or a piece of indiarubber) or of releasing a muscle already stretched. When a muscle, alive or dead, is *stretched*, heat is liberated in relatively large amount at first, but at a rapidly diminishing rate. When a stretched muscle is *released*, there is at first a rapid absorption of heat, followed by a more prolonged evolution of heat. In a complete cycle of lengthening and shortening the net result is a production of heat, which is greater the longer the interval between the two processes. These thermo-elastic effects are large enough to afford a notable complication in the measurement of the heat-production of a live muscle excited to contract. Their explanation is as follows:—(*a*) The muscle, like a fiddle-string, shortens on being warmed; conversely, according to the second law, it will warm on being

stretched and cool on being released. This explains the initial effects. (*b*) The muscle, like other colloidal jellies, takes some time to reach an equilibrium length on being stressed; consequently, on stretching it *more* work is done, and on releasing it *less* work is obtained than is accounted for by the elastic potential energy existing in it when it has reached its full equilibrium length. The balance in either case appears as an irreversible production of heat. This accounts for the secondary effects. The phenomena appear to be of physical as well as of physiological interest.—Sir James **Dobbie** and J. J. **Fox**: The absorption of light by elements in the state of vapour: Selenium and tellurium. In a previous communication (Proc. A, 1919, vol. xcv., p. 484) it was shown that the absorption of light by sulphur vapour reaches a maximum at a temperature of about 650° C., and that at this temperature the vapour density corresponds with the average molecular weight S_8. Selenium and tellurium behave much in the same way as sulphur, the absorption increasing up to a certain temperature, above which it again diminishes. In the case of selenium the maximum absorption occurs between 650° C. and 700° C., and vapour-density determinations show that the average molecular weight at this point corresponds to Se_2. With tellurium the maximum absorption is found to occur about 1200° C. The vapour of this element consists of diatomic molecules at 1800° C., but nothing is known of its constitution at lower temperatures. Its general similarity, however, to sulphur and selenium as regards absorption of light renders it highly probable that at 1200° C., and below this temperature, the vapour is much more complex than at 1800° C. The absorption spectra of selenium and tellurium are marked by the presence of large numbers of sharp narrow bands, and that of tellurium shows a wide absorption band of which the centre is approximately at λ 3800.—Sir James **Dobbie** and J. J. **Fox**: The absorption of light by elements in the state of vapour: Mercury, cadmium, zinc, phosphorus, arsenic, and antimony. These elements, unlike those of the sulphur group, do not show channelled absorption spectra when the Nernst filament is used as the source of light. Mercury, cadmium, and zinc, which are monatomic, transmit practically the whole of the light at all temperatures. Cadmium, however, shows a few narrow absorption bands, of which one at λ 3261 is the most striking. In the cases of the tetratomic elements, phosphorus, arsenic, and antimony, general absorption occurs and increases regularly with rise of temperature up to 1400° C. There is no indication of a maximum followed by a diminution of absorption. The peculiar absorption phenomena of the elements of the sulphur group are in all probability due to the breaking-down of complex into simpler molecules, *e.g.* S_8 into S_2, with the formation of molecules of intermediate complexity. With monatomic molecules no such dissociation can occur. With the tetratomic elements there is undoubted dissociation; but the changes are much less complicated than in the case of sulphur, the tetratomic molecules simply splitting up into diatomic molecules. It is, however, to be noted that the highest temperature at which silica tubes can be used is 1400° C. It is possible that at still higher temperatures further dissociation of the tetratomic elements would result, accompanied by absorption phenomena similar to those observed in the case of sulphur.—A. E. H. **Tutton**: Monoclinic double selenates of the copper group. This memoir deals with the four double selenates of the series $R_2M(SeO_4)_2,6H_2O$, in which M is copper and R is potassium, rubidium, cæsium, and ammonium. A complete crystallographic and physical investigation has been carried out, similar to the work previously published concerning the magnesium, zinc, iron, nickel, and cobalt groups, and to that on the analogous double sulphates. The results confirm the conclusions derived from all the groups previously studied, and in a peculiarly valuable manner; for the copper-containing group affords crystals with morphological angles and elements and physical constants which differ appreciably in their absolute values from those afforded by the other groups, in this respect resembling the double sulphates containing copper. Yet the relationships between the values for the four salts are precisely the same, leading thus to exactly the same general conclusions as in the cases of those other groups. Every group exhibits its own idiosyncrasies, and the copper groups do so in a specially notable manner. Yet the same progression, according to the atomic weight and atomic number of the alkali metal present, is exhibited in the case of every property, whether morphological, such as the crystal angles and the topic axial ratios, or physical, such as the double refraction and the molecular refraction; also the ammonium salt proves to be practically isostructural with the rubidium salt. The most recent work on the structure of the atom and the further elaboration of Moseley's law connecting the atomic number with the atomic structure and complexity has only strengthened the conclusion that the author's results are a natural consequence of the operation of Moseley's law: the progression in the crystal properties following the progression in the complexity of the alkali-metallic atoms, which exert so dominating an influence in determining the structure and properties of these crystals.—H. G. **Cannon**: Production and transmission of an environmental effect in *Simocephalus vetulus*. The experiments were undertaken in order to repeat, if possible, Agar's work on the production and transmission of an abnormality in *Simocephalus vetulus*. The magnitude of the abnormality, which consisted in a change in the curvature of the valves of the carapace, could be measured by the length/width ratio L/W. The results indicate that the abnormality can be produced by feeding a culture containing practically no other protozoon than Chlamydomonas. The L/W ratio was found to be too variable to allow of its measurement with sufficient accuracy on which to base considerations as to the existence or non-existence of a "reaction" to the abnormality of such a magnitude as that indicated by Agar. The experiments showed that no antibody was produced to eliminate the cause of the abnormality.—E. C. **Grey**: The enzymes of *B. coli communis*, which are concerned in the decomposition of glucose and mannitol. Part iv.: The fermentation of glucose in the presence of formic acid. By carrying out the fermentation of glucose by bacteria in the presence of calcium formate the author has been able to upset the normal balance which exists between certain of the products, and thus to show that they are in reality formed by separate enzyme actions. Hitherto an approximately constant relationship has been found between the formic acid and carbon dioxide on one hand, and the alcohol and acetic acid on the other. This relationship is shown to be rather accidental than essential. It results probably from the fact that the hydrogen which arises from the decomposition of formic acid co-operates in the formation of alcohol, and thus the two reactions of alcohol formation and carbon dioxide formation tend to keep pace with one another. The addition of more formic acid at the outset of the fermentation tends, however, to prevent the production of formic acid from glucose, and to destroy the ratio which normally exists between this formic acid and the alcohol and acetic acid, thus [illegible]ing that these products arise by at least two separate enzyme actions. Taken in conjunction with the author's previous finding, that lactic acid is formed

from glucose by *Bacterium coli* by a mechanism which is independent of that which gives rise to the other products, it is clear there that glucose may break down under the influence of these bacterial enzymes in three independent ways, giving rise to the following three groups of products :—(1) Formic acid, carbon dioxide, and hydrogen. (2) Alcohol, acetic acid, and succinic acid. (3) Lactic acid. These groups apparently represent three separate lines of cleavage of the glucose molecule under the influence of the enzymes of the bacterium in question. The author is of opinion that this manner of cleavage is fundamental. The experiments also show that alcohol is produced, in part at least, by reduction, and prove for the first time that such reduction does actually occur by the action of hydrogen liberated from the glucose, as well as that, in certain circumstances, the hydrogen derived from the added calcium formate exerts a reducing action and increases the yield of alcohol.—L. T. **Hogben**: Studies on synapsis. ii.: Parallel conjugation and the prophase complex in Periplaneta, with special reference to the premeiotic telophase. Synapsis in the Orthoptera has been the subject of considerable controversy. The earliest events of synapsis in the ovaries of the cockroach are traceable with much greater facility than in the testes. They involve in either case the parallel conjugation in pairs of the full diploid number of leptotene loops. Morse's account of the origin of the heterotype rings by separation of the diplotene threads along the line of cleavage is confirmed and amplified by a sequential analysis of the metaphase complex. It is seen that two chromosomes at this stage (*d* and *a*[1]) retain the looped condition of the post-synaptic bouquet until the others have divided —a fact which led earlier workers to interpret the genesis of the heterotype annular chromosomes according to the telosynaptic hypothesis. The accessories are not distinguishable in oogenesis from the autosomes. The vacuolation of the plasmosome during yolk-formation in the oocyte is described in detail, and a re-examination of material for a previous paper indicates that the so-called "chromatin" granules described by so many writers, as emitted during yolk-formation in the insect egg, are in reality products of the plasmosome. There is no evidence that in Periplaneta the plasmosome is related in any way to the chromatin organisation of the nucleus.

PARIS.

Academy of Sciences, June 7. M. Georges Lemoine in the chair.—C. **Moureu** and G. **Mignonac**: Acylketimines. Benzonitrile, magnesium, and an alkyl bromide give the product $C_6H_5.CR:N.MgBr$, and with an acid chloride acylketimines are obtained of the type $C_6H_5.CR=N.CO.CH_3$. Details of the general method of preparation and the melting points of six acylketimines are given.—G. **Bonnier**: The changes in plant forms obtained experimentally. Full descriptions of the changes brought about in seventeen species of plants by change of altitude. The plants were grown in similar soil in the plains and in the mountains, and the observations extended for a period of from six to thirty-four years.—A. **Rateau**: The theory of aerial and marine propulsive helices and of aeroplanes in rectilinear flight.—M. Kamerlingh Onnes was elected a correspondant for the section of physics in succession to the late Sir William Crookes.—G. **Julia**: Functions of two complex variables and limiting functions of analytical functions, uniform or multiform, of one variable.—R. **Thiry**: The conformal representation of doubly connected with rectilinear contours.—H. **Villat**: The conformal representation of doubly connected areas.—B. **Gambier**: The surfaces of translation of Sophus Lie.—L. **Dunoyer**: Magnetic induction in the soft iron compass correctors under the influence of the needles. Modifications of a formula given in an earlier communication required by the discovery of an error in sign.—L. **Barbillion** and M. **Dugit**: The rectilinear scale with equidistant divisions applied to the measurement and division of angles and measuring apparatus of constant sensibility. —Mlle. Paule **Collet**: The reproduction of speech by galena and sustained waves.—L. and E. **Bloch**: Production of the band spectra of nitrogen by electrons of low velocity. Earlier experiments of this nature have been made by the electrical method: the examination of the angular points in the curve of the current produced by the electrons. In the work here described a quartz prism spectrograph was employed and the nitrogen bands were directly observed. It was found to be possible to get the nitrogen radiation at a critical potential of about 10 volts. Hence band spectra, like line spectra, can be excited by electron shock with a voltage clearly lower than the ionisation potential (18 volts).—C. **Benedicks**: The electrothermic effect in a homogeneous conductor of constant section.—C. **Raveau**: Variance and the means of presuming the value of it without the aid of a formula.—P. **Bary**: The viscosity of colloidal solutions. A study of the swelling of colloids in suspension based on Einstein's formula for the viscosity of liquids holding solid matter in suspension.—M. **Delépine** and L. **Ville**: The chloride of bromine: its combination with ethylene. Forty years ago Maxwell, Simpson, and James showed that ethylene chlorobromide, $ClCH_2.CH_2Br$, was the product of the reaction of ethylene on "chloride of bromine" in a solution of hydrochloric acid. Recent physico-chemical work, on the other hand, goes to prove that chloride of bromine does not exist, and that the substance passing under that name is merely a mechanical mixture of bromine and chlorine. The authors have examined the action of ethylene on dry "chloride of bromine," and find that the compound C_2H_4ClBr is undoubtedly the main product. From this work the conclusion is drawn that, in some cases at least, physico-chemical data cannot be relied upon to prove the non-existence of a chemical compound.—H. **Gault** and R. **Weick**: A case of isomerism in the series of the aromatic α-ketonic acids. The existence of two isomeric phenylpyruvic ethers is proved, and the conditions under which one can be converted into the other determined. —J. **Bougault** and J. **Perrier**: New researches relating to the action of hydrocyanic acid on glucose. The fact that in presence of an excess of potassium cyanide the glucoses form cyanohydrins quantitatively suggested that this reaction might be utilised for the exact estimation of glucose, and the conditions for accurate estimations are given. When the glucose is in excess the cyanide is rapidly converted into the non-poisonous cyanohydrin, and an experiment is cited in which 0·25 gram of potassium cyanide mixed with 6 grams of honey and 6 c.c. of water were given to a guinea-pig after the mixture had been allowed to stand fourteen hours to complete the reaction. The animal showed no signs of poisoning. The consequences of these results from a toxicological point of view are discussed.—G. **Guilbert**: The application of cirrus clouds to the prediction of the weather.—H. **Ricome**: The phenomenon of torsion comparable to the rolling-up of tendrils produced experimentally.—F. **Moreau**: The different aspects of lichen symbiosis in *Ricasolia herbacea* and *R. amplissima*.—J. **Stoklasa**: The action of hydrocyanic acid on the organism of plants. The spores of *B. subtilis* and *B. mesentericus vulgatus* resist the toxic action of air containing 3 per cent. of hydrocyanic acid by volume, but exposure of twenty-four hours to 3·5 per cent. by volume arrests further development. *Mucor mucedo, M. stolonifer,* and *Penicillium glaucum* behave similarly, and *Aspergillus*

glaucus requires a strength of 4 per cent. for destruction. Micro-organisms offer very great resistance to the action of hydrocyanic acid. The conditions under which seeds can be exposed to hydrocyanic acid vapour without damage have been worked out, and experiments cited showing how this method can be used for the practical disinfection of seeds affected with parasites.—A. **Krempf**: The blastodermic origin of the enteroids and of the enteroido-pharyngeal complex in the Anthozoa.—W. **Kopaczewski**, A. H. **Roffo**, and Mme. H. L. **Roffo**: Anæsthesia and anaphylaxy. The authors have found that anæsthetics and analgesics possess the well-marked property of diminishing the surface tension of serum. On the other hand, it has been proved that all the substances used for the prevention of anaphylactic phenomena, such as lecithin, the alkalis, and soaps, also have the property of lowering the surface tension. Experiments are given on the suppression of anaphylactic shock by anæsthetics. The results obtained confirm the view that it is not the nervous system which is mainly affected by the anaphylactic shock, but a reaction of colloidal flocculation leading to asphyxia from the obstruction of the capillary networks.—A. Medical Research and the Practitioner.

IN the interim report[1] issued recently by the Consultative Council on Medical and Allied Services, under the chairmanship of Lord Dawson of Penn, the proportion given to research is disappointingly small. Perhaps this was inevitable. The medical organisation suggested includes effective laboratory equipment at every stage from the domiciliary work of the practitioner to the conducting of prolonged researches by the Medical Research Council; but the portions dealing with research proper are very generalised. A document like this should be a new charter for medicine, and the scientific mind naturally expects to see the scientific groundwork fully developed. For increased and accelerated research is essential to the continued expansion of scientific medicine. In the report it is hoped

> "that the scheme of services which we suggest would facilitate enquiry into the causes of disease and the possible remedies. The facts which indicated the need for such enquiry might, we think, often be brought together in the first instance by the medical practitioners in a given locality."

It is difficult to justify the hesitating note of these sentences. Medical practice bristles with unsolved problems; but usually the practitioner is inadequately trained to discover them. Sir James Mackenzie shows what a general practitioner can do when he has the interest and the capacity to train himself. The war has unveiled many gaps in scientific medicine. Even the war reports of the Medical Research Council, not to refer to the many others, prove that the science of medicine will not advance merely by a re-shuffling of the medical army, but by greater intensity of research and discovery.

Medicine has to face the fact that, for practical purposes, it knows nothing about the cause of measles, scarlet fever, mumps, influenza, rheumatic fever, cancer, or other forms of malignancy; nor is the knowledge of the causes of dead and premature births more than elementary. These are only a few illustrations taken from the Medical Research Committee's fifth annual report. It is reasonable to expect that, in a scheme that brings the medical profession into a unity, the clotted masses of problems facing the general practitioner and scientific worker alike would be sketched with precision and force. The report does add that

> "there are great and important opportunities for research in preventive medicine, which at present are scarcely dealt with by any organisation, and mostly are not attempted by individuals. Encouragement of research in the prevention of disease should, we think, be developed, for the materials are everywhere, and the results would undoubtedly be valuable."

From this the lay public would not readily gather that the future value of the general practitioner to the State depends on the development of research in at least the following sciences: biology, physiology, bio-chemistry, pathology, and experimental therapeutics. To the raw materials of such researches the various classes of medical practitioners can contribute; but they have little stimulus to do so unless they keep more closely in the currents of the scientific work of the schools.

The report indicates that, for the purposes of research into fundamental problems, "the profession would no doubt look to the Universities and the Medical Research Council for guidance and assistance." When we reflect that the medical profession has to deal with sanatoria for tuberculosis, recuperative centres, hospitals for curable or incurable mental disease, institutions for the feeble-minded, epileptic colonies, orthopædic centres, hospitals for infectious diseases, not to mention general hospitals and the innumerable fresh points emerging in every man's practice, there is abundant occasion to look both for "guidance and assistance."

What we miss here is a compact and well-loaded presentment of the case for research from the general practitioner's point of view. At present neither general practitioners nor consultants have an adequate conviction that more and more as time goes on the value of their work will depend on the capacity to understand and to prevent the beginnings of disease, and that, without effective training in research at some stage of their career, they can make little headway in pre-

[1] Ministry of Health Consultative Council on Medical and Allied Services. Interim Report on the Future Provision of Medical and Allied Services. Pp. 28. (London: H.M. Stationery Office, 1920.) Cmd. 693. Price 1s. net.

T

ventive medicine as now understood. The general practitioner's part in "field" and "team" research might well form the subject of a special reference to the Consultative Council on Medical and Allied Services. If the world of general practice does not realise that research is of vital importance to every branch of medicine, such is certainly not the case with the world of science.

Theory of Dioptric Instruments.

Ferraris' "Dioptric Instruments": Being an Elementary Exposition of Gauss' Theory and its Applications. Translated by Dr. Oscar Faber from Prof. F. Lippich's German translation of Prof. Galileo Ferraris' Italian work entitled "The Fundamental Properties of Dioptric Instruments." Pp. xxxi+214. (London: H.M.S.O., 1919.) Price 4s. net.

THE original of this translation was published by Prof. Galileo Ferraris, of Turin, in 1876. As a copy of this original could apparently not be procured, the English translation was made from a German one by Lippich, which appeared in 1879. At the time of its appearance the book unquestionably marked a great advance in the treatment of its subject, and well deserved the extremely favourable review with which Abbe honoured the German translation in the first volume of the *Zeitschrift für Instrumentenkunde.*

Abbe himself, however, has to be credited with far greater advances in the theory of image-formation by optical instruments with which the book before us deals, for his purely geometrical treatment of the problem leads to the same results without being limited to the infinitely constricted "threadlike space around the optical axis" which still plays so large a part in text-books, although, with light of finite wave-length, nothing of any optical interest can possibly happen within it. On the other hand, Abbe was the first to deal systematically with the actual course of light through instruments in accordance with the limitations imposed by restricted apertures and by deliberately placed diaphragms, and inasmuch as the great majority of actual instruments are used only at fixed or nearly fixed conjugate distances, the actual course of the rays so determined is of far greater importance and value, both in the designing of instruments and in the discussion of the effects produced by them, than the rays referred to the Gaussian principle and focal planes and points which form a convenient *pons asinorum* in the general theory of lens systems.

Ferraris' treatment of the Gaussian theory is, however, less open to the objections just alluded to than that adopted in most books, and in dealing with the Galilean telescope he comes remarkably close to the correct treatment of the problem of its field of view, which is so easily obtained now by Abbe's theory of the entrance- and exit-pupil of instruments. Beginners and users of optical instruments desiring to acquire a general knowledge of their elementary theory will also welcome the numerous and frequently elegant graphical solutions of the various problems which are given throughout as alternatives to numerical calculations by algebraical formulæ. The chief and decidedly regrettable omission is that the simple problem of achromatism is not dealt with at all. It is, of course, not a part of the Gaussian theory, and the omission is therefore justifiable; but it is so closely bound up with the proper explanation of the effects produced by compound object-glasses and eyepieces that the book would certainly have gained in value if the subject had been included.

The book is not so free from misprints as one would wish, and there is a really bad muddle on pp. 87–94, where the properties of thick lenses are discussed. This is not a case of a simple misprint or transposition of diagrams, but of actual errors by either the original author or one of the translators. Thus on p. 87 a thick biconvex lens is stated to be convergent if its thickness is less than one-third of the sum of the radii (both taken as positive, with $\mu=1 \cdot 5$). This should be three times instead of one-third. Then, on p. 93 a meniscus with the shorter radius on its concave face is stated to be always convergent; and on p. 94 the meniscus with the shallower curve on the concave face is credited with being divergent, telescopic, or convergent according to thickness. The actual facts are, of course, the other way about. Immediately after this the properties of a concentric lens are correctly stated.

On p. 144 the strange conclusion is reached that of two eyepieces of the same equivalent focal length that one is to be preferred which has the *closer* eye-point. This is directly contrary to the experience of every observer.

In the calculations of the properties of the human eye, or rather of its "simplified model," the author sets a very bad example by starting with data given with three significant figures and undoubtedly uncertain even then in the third figure, and calculating all the deduced figures with six, and even seven, significant figures (pp. 71–75). The idea of beginners that the percentage-accuracy of observed data can be indefinitely increased by putting them through the mathe-

matical mill with an imposing number of figures is sufficiently difficult to eradicate without such examples by teachers!

Apart from a few blemishes of the kind alluded to, the book may still, forty-four years after its first appearance, be recommended as worthy of careful study. A. E. C.

The International Research Council.

International Research Council: Constitutive Assembly held at Brussels, July 18 to July 28, 1919. Reports of Proceedings. Edited by Sir Arthur Schuster. Pp. iii+286. (London: Harrison and Sons, 1920.) Price 10s. 6d.

THE Constitutive Assembly of the International Research Council, which met at Brussels on July 18, 1919, established for certain subjects new international organisations to replace those existing before the war, and in this volume we have the official text of the statutes there adopted or proposed, as well as the *procès-verbaux* of the different meetings which were held.

It will be remembered that in October, 1918, a conference of the scientific academies of the Allied nations was held in London at the invitation of the Royal Society to consider the action which should be taken in regard to international associations; for some had lapsed during the war, and others were unlikely to meet in their old form for some years to come. The resolutions then agreed to were carried further at a second conference which was held at Paris in November of the same year, when the International Research Council was formed, and an executive committee appointed to prepare proposals to be submitted to the Constitutive Assembly at Brussels. The meeting at Brussels formed the third stage in the formation of the new international organisation which had been decided upon in London, and at it the statutes of the International Research Council and of the Unions for Astronomy, for Geodesy and Geophysics, and for Pure and Applied Chemistry were approved.

The legal domicile of the International Research Council is at Brussels, where the general assembly will meet from time to time; but this in no way restricts the Unions, the members of which determine the places of their bureaux and of their periodical meetings as they please. The countries participating in the foundation of the International Research Council are Belgium, Brazil, the United States, France, the United Kingdom, Australia, Canada, New Zealand, South Africa, Greece, Italy, Japan, Poland, Portugal, Rumania, and Serbia, in addition to which the following neutral countries were invited to join the Council: China, Siam, the Argentine Republic, Chile, Denmark, Spain, Mexico, the Principality of Monaco, Norway, Holland, Sweden, Switzerland, and also Czecho-Slovakia.

Besides the three Unions which were definitely established at the Brussels meeting, proposals were made that several others—mathematics, physics, radiotelegraphy, geology, biology, geography, and bibliography—should be formed, and draft statutes for these were presented in order that the executive committee might communicate them to the National Research Councils of the different countries for the desirability of forming such international unions to be considered. The machinery therefore exists for constituting an international organisation in any branch of science where it will be of service. Several countries have already formally signified their adherence to the International Research Council, and some also to the Unions which have already been formed.

It has been proposed that the draft statutes of the Mathematical Union should be discussed at an international meeting at Strasbourg this autumn, and doubtless representatives of other branches of science will hold similar meetings in due course to consider the desirability of forming unions of their own.

For all such meetings this volume of the proceedings and reports of the Brussels meeting will be of great value, for the general organisation differs from that of earlier associations, and may at first sight seem to be somewhat cumbrous; but a perusal of the documents now published will show that each union can provide itself with the constitution best suited to its own requirements, while conforming at the same time to the essential features of the International Research Council.

Problems of Population.

(1) *Problems of Population and Parenthood. (Being the Second Report of, and the Chief Evidence taken by, the National Birth-rate Commission, 1918–20.)* Pp. clxvi+423. (London: Chapman and Hall, Ltd., 1920.) Price 25s. net.

(2) *The Social Diseases: Tuberculosis, Syphilis, Alcoholism, Sterility.* By Dr. J. Héricourt. Translated, and with a final chapter, by Bernard Miall. Pp. x+246. (London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1920.) Price 7s. 6d. net.

(3) *The Venereal Problem.* By E. T. Burke. Pp. 208. (London: Henry Kimpton, 1919.) Price 7s. 6d. net.

(1) MR. JOSEPH CHAMBERLAIN set a precedent when he gave the name of "Tariff Commission" to a body created by him-

self alone. Previously the word "Commission" had been generally applied only to bodies created by Royal or Parliamentary authority, and having power to call witnesses before them, to whom each member of the Commission could put questions. Where bodies had been created for the purpose of hearing evidence tendered by voluntary witnesses, as had been done with advantage by the Charity Organisation Society, they were usually called "special committees." They are now often called "Commissions" in imitation of Mr. Chamberlain's action, and if it is clearly understood that they have no compulsory powers, there seems no harm in applying that term to them as denoting their method of action rather than the authority under which they act. In one respect they are not unlike many Royal Commissions. They consist largely of people who are known to have formed strong opinions on one side or the other, and accordingly their conclusions, if any sort of unanimity can be arrived at, are often in the nature of a feeble compromise, or, on the other hand, if both parties stand to their guns, are split into majority and minority reports. Even so, such reports may be useful as collections of facts and as presenting to the public materials for forming its own judgment.

The test, therefore, is: Are the results obtained of value? We think the report of the "National Birth-rate Commission," which has been published under the title of "Problems of Population and Parenthood," very fairly answers this test. It shows a continuous reduction in the birth-rate in England and Wales from 24 per thousand of the population in 1913 to 18 per thousand in 1918. For the further elucidation of the problems arising out of this fact, the Commission unanimously passed resolutions in favour of the establishment of a permanent Anthropometric Department under the Ministry of Health, and of a General Register. The practice of restricting the family has begun with educated and professional persons, and is gradually spreading through the whole community. That it should be so seems to be regarded by the majority of the Commissioners as inevitable, but they acknowledge the value of the unrestricted family as a training in self-sacrifice, mutual help, and efficiency, conducing to a better prospect of happiness than the restricted family in general can afford. When the practice of restriction of families is adopted, the tendency is to limit the number to that which will not restore the deficit caused by the loss of the generation that is passing. We thus get a diminishing population, leading to what has been called "race-suicide."

The conditions in which an increase of the population is not desirable do not exist in the British Empire. So far as they exist in Great Britain, emigration (as Sir Rider Haggard suggests) seems to be the right means of meeting them. The Commission reports that there is no moral issue raised in respect of the limitation of the family when there are good reasons for such a course, but that the moral difficulty arises as to the means which may be used for that purpose. Ecclesiastical authorities allow of a limitation of intercourse, which does not afford a complete security, but not of any other method. If, however, the rightfulness of the limitation be admitted, the method by which it is to be effected would seem to be a question of physiology and perhaps of æsthetics rather than one of ethics. Some of the methods suggested are repulsive, and it is to be hoped none of them will become popular.

(2) Dr. Héricourt approaches the subject from a different point of view in dealing with sterility as one of the social diseases of France, where the birth-rate has been steadily falling and depopulation in progress for many years. He attributes this to voluntary restriction, and shows that the richer inhabitants are the less fruitful, and the poorer the more fruitful. He proposes a variety of remedies, ranging from the moral encouragement of large families to the taxation of celibates and of small families. He rejects the expedient of a direct bounty from the State to the parent. He would use all legal means to suppress publications in which the limitation of families is recommended, and to prevent the sale of articles designed to effect that object.

(3) The venereal problem is a subject common to all the three volumes under review, and it is curious to note that it is only recently that it has been possible to discuss it with the freedom that all alike use. This is in some degree due to the war. Since the days when Alva brigaded his "quatre cents courtesanes à cheval, belles et braves comme princesses, et huit cents à pied, bien à point aussi," and long before, indiscriminate sexual indulgence has been one of the incidents of a time of warfare. The risk attaching to it may be mitigated by suitable measures of military discipline, but the effectual application of similar measures to the civil population would be difficult, if possible. The urgency of the problem lies in the possibility of communicating the infection to innocent persons and to unborn children, and in the loss to the community arising from the destruction of life and efficiency caused by the disease. In the face of these evils it is not necessary to discuss the old view that syphilis was a disease the risk of which was voluntarily incurred in the

performance of an immoral act. If prostitution could be abolished, venereal disease would probably in time become extinct, but no means have yet been discovered by which, mankind being what it is, prostitution can be abolished.

All the authors alike urge propaganda. The National Birth-rate Commission thinks that the Ministry of Health should direct the attention of the public to the urgent duties of citizens in the matter. Dr. Héricourt says that we must act upon the will of the individual by persuasion through fear and through interest, and mentions a work by Prof. Fournier that has been circulated by the French Society for Sanitary and Moral Prophylaxis as well calculated to effect the desired persuasion. Mr. Miall, who adds a chapter of his own to his translation of Dr. Héricourt's work, urges that proper instruction should be given in the dangers of venereal disease. Mr. Burke, who has been an acting lieutenant-colonel in the Royal Army Medical Corps, argues forcibly that the public must be made more acquainted with sexual matters, increase its knowledge of the prevalence and dangers of venereal disease, and be induced to appreciate and to assist actively in the means to be provided for treating and finally stamping out of existence those disorders. The education, he says, must begin with the child. The adult must be impressed with the importance, the reality, and the dangers of venereal disease. The medical profession must set its teeth with determination to fight the menace out of existence. Mr. Burke's treatise, which is illustrated by six diagrams, is likely to be of value in effecting the common purpose of enlightening the public on these important matters. E. B.

The Elements of Hardy Fruit Culture.

Practical Hardy Fruit Culture. By Richard Staward. Pp. 216. (London: The Swarthmore Press, Ltd., 1920.) Price 6s. net.

ALTHOUGH in many respects this small treatise on hardy fruit culture may be commended to beginners as a clear, concise, and elementary guide on the subject as applied to garden conditions, describing methods followed with success by the author at Panshanger Gardens, Hertford, it cannot be considered as having achieved the main purpose for which it was written. The author has set himself to provide a useful book for those, forming a numerous class at the present time, who are adopting hardy fruit culture as a business and know little or nothing of such work. The methods recommended, however, are essentially those for the private gardener, as distinct from the commercial fruit-grower. Taking the case of distances for planting trees as an example, it is advised that bush or pyramid apples on free stocks should be planted 12 ft. apart, and those on the Paradise stock from 6 ft. to 9 ft. apart. For standard apple-trees 12 ft. is mentioned as the distance, if space is limited. For commercial work these distances should be at least doubled for varieties of vigorous growth, where the trees are to be treated as permanent and not as fillers. A general criticism may also be made of the lists of varieties recommended, which are almost invariably too long, and contain sorts which are of at least doubtful commercial value.

The sections devoted to the diseases and pests of the respective fruits make mention for the most part of the more serious troubles, and of some which are relatively trivial; but there are important omissions, such as silver-leaf of plums, bitter-pit of apples, and reversion of black-currants. The remedies proposed are typical garden methods and are often inappropriate for commercial plantation use. In some cases they would appear to miss the mark entirely, as when, for instance, the spraying of black-currants with lime-sulphur, or, as the author describes it, "bisulphide of calcium," against big-bud-mite attack is advised after the fruit has been gathered. By that time the mites are safely within the cover of the newly formed buds. It may also be questioned whether the author has made the best use of the space at his disposal by dealing with such fruits as outdoor grapes, mulberries, medlars, and apricots, by description of methods of propagation which are not adopted in general practice, and by detailed accounts of the training of special forms of trees which are never considered except for particular purposes in private gardens.

The illustrations are original, and some are of interest.

Our Bookshelf.

Experiments in the Breeding of Cerions. By Paul Bartsch. (Department of Marine Biology of the Carnegie Institution of Washington. Vol. xiv.) (Publication No. 282.) Pp. 55+59 plates. (Washington: The Carnegie Institution of Washington, 1920.) Price 3 dollars.

CERIONS are land snails, well represented in the Bahamas by five species. They occur on the ground, under the edges of stones, among dead leaves, on grass, and on bushes. On an exposed place they attach themselves to the support by a thin epiphragm which also serves to prevent

desiccation. They can æstivate for a considerable time. In habit they are largely nocturnal, and are most active on misty nights. They feed mainly on fungi. They mate on the ground, and, though hermaphrodite, one functions as a male and the other as a female. The eggs are laid singly at the base of tufts of grass and beneath the surface. It takes between two and three years for an individual to reach full maturity.

For experimental purposes a number of Bahama forms were introduced into the Florida Keys, which present a considerable range in climatic factors and vegetation. There is on many of the Keys an indigenous species of Cerion, *C. incanum*, Binney, but it is not nearly related to any of the forms introduced; and one of the interesting results obtained by Dr. Bartsch was that the cross-breeding of the native species with the introduced *C. viaregis* brought about a state of flux. Had the resulted colony been discovered by one who did not know the history, a description would have been given of a very variable species. The inference is that similar complexes of unknown origin are likewise the product of cross-breeding. The case is peculiarly interesting because *C. incanum* and *C. viaregis* are very remotely related. "The fact is, that it is very surprising that organisms presenting such great differences in organisation should be able to cross at all, and it is still more remarkable that they should have produced fertile crosses." The author is inclined to believe that the crossing has an "energising effect" on the new product, but recent work on "hybrid vigour" leads one to think rather that what occurs is a happy pooling of hereditary items which corroborate one another. The general picture the author's results leave in the mind is that species separated for ages might be brought together by changes of level, so that crossing resulted. There followed an efflorescence of new forms which were later subjected to isolation on islands and promontories where inbreeding gradually eliminated diverse characters, eventually resulting in the more or less homogeneous expression which now marks in the Bahamas a multitude of insulated colonies.

Space and Time in Contemporary Physics: An Introduction to the Theory of Relativity and Gravitation. By Prof. Moritz Schlick. Rendered into English by Henry L. Brose. With an introduction by Prof. F. A. Lindemann. Pp. xi+89. (Oxford: At the Clarendon Press, 1920.) Price 6*s*. 6*d*. net.

HERE is a readable book, excellently translated, for which we have again to thank Mr. H. L. Brose. Though it is called an introduction to the theory of relativity and gravitation, it is more strictly an essay on "The Inseparability of Geometry and Physics in Experience," to quote the title of its fifth chapter. The main problem in presenting the work of Einstein to the physicist is to enable him to see how obstinately metaphysical he is.

"Time and space can be dissociated from physical things and events only in abstraction. The combination or oneness of space, time, and things is alone reality; each by itself is an abstraction." Many will say such statements are metaphysical in nature. In a sense, indeed, any statement is metaphysical which is concerned with logic. The real merit of Einstein's theory is that it does not trouble to ask what space and time are, or how far they may be logically separated from things. It does not attempt the separation. It goes straight ahead, keeping them all together until a result is arrived at which may be tested without any doubt or dispute as to its logical meaning, by the only method of exact observation, the perception of complete coincidence. It renders Newton's highly metaphysical definitions of space and time unnecessary; but while philosophers pause to see how they have to re-model their definitions, the physicist may congratulate himself that history has again proved that the real advances are made by those who, with open mind, continue in their endeavour to order the direct facts of experience in the most comprehensive manner.

History of the Great War, based on Official Documents. By Direction of the Historical Section of the Committee of Imperial Defence: Naval Operations. Vol. i. By Sir J. S. Corbett. Pp. xiv+470+case of 18 maps. (London: Longmans, Green, and Co., 1920.) Price 17*s*. 6*d*. net.

THIS important volume, the first of a series which is expected to run to four or five volumes, is described on its cover as the "official history of the war." This description is modified within by the explanation that, though it is based on official documents inaccessible to the general public, its views and opinions are those of its author alone, for which the Admiralty accepts no responsibility. This explanation unquestionably diminishes the official nature of the publication; but, on the other hand, it immensely increases its historic interest and its scientific value. For Sir Julian Corbett is a master of naval lore; he is deeply versed in the strategy and the tactics of the great captains of the old days. Consequently he has come to the study and interpretation of the masses of information concerning the late war laid before him by the Government with a splendid reserve of knowledge and with a perfected apparatus of criticism, and it is eminently satisfactory to be assured that he has had a perfectly free hand in dealing with his material and in drawing his conclusions.

The volume deals in a most illuminating manner and with a wealth of new information with the situation at the outbreak of the war, with the problems which the Navy had to face and solve during the critical months of 1914, and finally with the thrilling battle of the Falkland Islands. We await with eager anticipation the remaining volumes of the series. The maps, it may be added, are of the highest value and importance.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

The Constitution of the Elements.

In continuation of my letter in Nature of March 4, further experiments on mass-spectra have been made, the results of which may be briefly announced as follows:

Boron (atomic weight 10·9) is a complex element. Its isotopes are 10 and 11, satisfactorily confirmed by second-order lines at 5 and 5·5. Fluorine (atomic weight 19·00) is apparently simple, as its chemical atomic weight would lead one to expect.

The results obtained with silicon (atomic weight 28·3) are somewhat difficult to interpret, and lead to the conclusion that this element has isotopes 28 and 29, with possibly another 30.

Bromine (atomic weight 79·92) is particularly interesting, for, although its chemical atomic weight is so nearly 80, it is actually composed of approximately equal parts of isotopes 79 and 81.

Sulphur (atomic weight 32·06) has a predominant constituent 32. Owing to possible hydrogen compounds the data are as yet insufficient to give a decision as to the presence of small quantities of isotopes of higher mass suggested by the atomic weight.

Phosphorus (atomic weight 31·04) and arsenic (atomic weight 74·96) are also apparently simple elements of masses 31 and 75 respectively.

No line given by the above elements shows any measurable divergence from the whole number rule.

Cavendish Laboratory, June 20.

Applied Science and Industrial Research.

In my reply to Mr. Williamson, published in Nature of June 3, I stated that research workers and their assistants, aided by the Department of Scientific and Industrial Research, during the year 1918–19 received on the average 53*s*. weekly.

Sir Frank Heath has directed my attention to the unwarranted inference I have drawn. I assumed that the grants made were all annual grants, but I am informed by the Department that this is not the case; less than half the grants to research workers and students were grants for twelve calendar months' work; the sum of 14,170*l*. expended included nine grants for apparatus and grants for casual labour. Actually, eighty-five research workers and students received rather less than 13,000*l*. I am informed also that professors' recommendations are followed in making these grants, both with regard to recipients and to the amounts allotted.

Without expressing any further opinion as to the adequacy of grants to individuals, detailed information not having been supplied, I should be glad if you would afford me the opportunity of expressing my regret that in criticising the grants I unwittingly misconstrued the figures given on pp. 9 and 72 of the Report of the Committee of the Privy Council for Scientific and Industrial Research for the year 1918–19.

Science and Scholasticism.

Dr. Singer's review of my book "Medieval Medicine" in Nature of April 1 has only just come under my notice. The mails separate us from England more than before the war; may that be my excuse for a belated word? I have nothing to say for the book, it is thoroughly documented and must speak for itself; but may I say a word for poor Aristotle and Hugo da Lucca, whom I have brought under the reviewer's strictures?

Dr. Singer suggests that Aristotle has come into appreciation again because we have found that he made observations on animal life. Is not the reason rather that now that we ourselves have come to think through our observations to the principles beneath, we have found that Aristotle was usually before us? As Prof. Wundt said, after spending a lifetime at experimental psychology: "It is only the animism of Aristotle which, by joining psychology to biology, provides a plausible metaphysical explanation for the data furnished by experimental psychology." In nearly everything else where this generation has thought deeply enough they have found Aristotle before them whenever he had considered the subject. That is why we have come to appreciate better the medieval regard for him.

Hugo da Lucca must be allowed to rest on his own work just like Aristotle. Any man who operated on the skull, the thorax, and the abdomen seven hundred years ago, using a metal tube to secure the patulousness of the intestines while he was making an intestinal anastomosis, who got union by first intention and boasted of it, and whose cicatrices were "pretty and linear, so that they could scarcely be seen," may be trusted to posterity in our time. How he could have done such things without an anæsthetic is impossible to understand, so therefore the hints that we have of anæsthesia at that time must be taken as historic. We do not need to go to manuscripts for this; there are dozens of text-books of professors of surgery in the thirteenth century that were printed in the Renaissance time. The Renaissance printers had marvellously good judgment, and the authors they printed in their magnificent editions were worthy of the time and labour they devoted to them. We have no word from Hugo himself, but his son wrote a whole volume with regard to him which surely Dr. Singer must know, though it is very hard to understand the position that he takes if he does know of it.

It is always amusing to note how the saying of anything good about the Middle Ages arouses opposition. John Fiske's declaration, "there is a sense in which the most brilliant achievements of pagan antiquity are dwarfed in comparison with these (of the Middle Ages)," must wait for acceptance. When I ventured to say in a volume on "The Thirteenth the Greatest of Centuries," that they had fine technical schools and developed engineering, most people shied; and yet we have their stained glass, illuminated books, wonderful ironwork, carving, and all the rest that we are founding technical schools to secure, and the engineering of their bridges and cathedrals is a marvel.

The modern man of science balks at this. Here in the United States the authors of "A Short History of Science" (New York, 1918), professors at the Massachusetts Institute of Technology, treated the science of the Middle Ages in a couple of paragraphs, the most important part of which is: "In the thirteenth century it becomes plain that a new spirit is arising in Europe. . . . Thomas Aquinas writes his famous 'Imitatio Christi.'"

Jas. J. Walsh.

110 West 74th Street, New York, May 26.

THE dialectical methods of the Middle Ages, admirably adapted to the sharpening of wits and the entertainment of audiences, have long been regarded by men of science as an inferior means of arriving at truth. I have no wish to enter into controversy with my friend Prof. Walsh as to the general merits of Aristotle. Yet I will venture to sum up in a sentence what I believe to be the conclusions of the overwhelming majority of modern Aristotelian scholars and of scientific men who have investigated the works of the master: *Aristotle's physical science is almost worthless from the modern point of view; it has scarcely any serious basis of observation and none of experiment; his biological works, on the other hand, show him to have been an admirable and careful observer of animal life.* He was thus an excellent naturalist but a very poor physicist. I will further endeavour to epitomise the verdict of most scientific students of the Middle Ages on his position in medieval science. *It was chiefly Aristotle's physical works that earned for him his scientific reputation in the Middle Ages; his biological works exerted little influence until the sixteenth century.* Those who assent to these propositions will not agree that "we have come to appreciate better *medieval* regard for him."

As regards Hugh of Lucca, I am aware of the existence of the "Chirurgia" of Theodoric, and that he was perhaps the son of Hugh, though, to my mind, Prof. Walsh has greatly exaggerated the scientific value of his work. But Theodoric's treatise, though certainly very interesting to us, was not greatly prized by the Middle Ages. Hence copies of it are very rare, and among the fifteen thousand or so medical MSS. that have survived in this country only one (Ashmole 1427, fourteenth century) contains it. A treatise possibly founded on it has survived in one English codex of somewhat later date (Magd. Coll. Cambridge, Pepys, 1661). Theodoric's treatise was not printed until 1498. I see nothing in it, or in what Prof. Walsh now says of it, to justify a modification of my criticism. The English reader who cares to learn more of Theodoric will find a sympathetic account of him in Sir Clifford Allbutt's "Historical Relations of Medicine and Surgery," and a very full analysis of his "Chirurgia" in E. Gurlt's "Geschichte der Chirurgie."

The judgment of the Renaissance printers in their selection of medical works is a matter of opinion. The sixteenth century had run a quarter of its course ere they made Hippocrates accessible (earliest Latin edition, Rome, 1525; earliest Greek edition, Venice, 1526). By that time the ponderous "Kanun" of Avicenna had already passed through at least twenty-two editions (Editio princeps, Strassburg, 1472). Those who rate Hippocrates higher than Avicenna—or than Theodoric—will rate the judgment of the Renaissance printers—and readers—accordingly.

Against Prof. Walsh's suggestion that I am opposed to any good being said of the Middle Ages I am sufficiently protected by my published works. However these be estimated, they will yet, I hope, guard me against the accusation of having neglected that period. Under such protection as they may afford I would add my regret to that of many of Prof. Walsh's other admirers that he does not use his great learning and literary gifts to portray medieval life as it was instead of as that of a *Civitas Dei*, which it was not. Whatever the scientific aspirations of the age, the scientific achievement was very small. The explanations of this failure are various, but in denying the fact Prof. Walsh belongs to an exceedingly small band of scholars whose conclusions seem also, to some of us, to be shaped by certain preconceived ideas. But we shall not, on that account, value the less any contribution to knowledge that he may make.

Oxford, June 12. CHARLES SINGER.

Commercial Parasitism in the Cotton Industry.

THE opinion of Sir George Watt in NATURE of February 23 that the report to the Board of Trade of the Empire Cotton Growing Committee is "ingeniously elaborated," but leaves a "confused impression," may justify a brief consideration of an allied phase of the subject. Why "the whole history of cotton improvement is most disheartening" may be explained if an essential feature has been omitted. The argument for research is ably presented in the pamphlet issued at Manchester by the Provisional Committee on Research and Education for the Cotton Industry, but with no reflection of the actual state of production.

Not only should planters have industrial information, as recognised in Sir George Watt's proposal of a central research institution at Manchester, but on the part of manufacturers, financiers, economists, and commercial leaders there is acute need of agricultural information. Industrial interest in cotton improvement must be made effective through the commercial channels that lead back to the farmer. Problems of agricultural application must be solved, in addition to developing superior varieties, devising better cultural methods, and controlling diseases or insect parasites. The elaboration of the cotton research programme may be entirely logical, but without an effective tie-back to the farmer there can be no prospect of a general application of the results of technical investigation, either industrial or biological, to purposes of production.

The central cotton institution at Manchester should be equipped for any elaboration of research that may be necessary to determine and demonstrate to manufacturers the relation of the system of buying to the improvement of production. The parasitic tendencies of the present commercial system are not limited to the speculative features that are being restricted by law or to the taking of undue profits, but lead to enormous agricultural and industrial waste through the production and manufacture of inferior fibre, passed on to the consumer in weaker and more perishable fabrics.

To expect manufacturers to be interested in the cotton plant or in the details of farm operations in the growing of cotton might be unreasonable, but at least the financial aspects of cotton production would receive attention if manufacturers knew how their interests are prejudiced by the present commercial system. Instead of serving as a conductor of interest in improved production from the spinner to the farmer, the commercial system has the manufacturers and the growers fenced apart and misinformed regarding the general needs of the industry.

Manufacturers are accustomed to pay more for good cotton, and naturally suppose that the farmers who raise better fibre receive higher prices for their crops, but investigation will show that most of the profit is absorbed by the buyers. The commercial idea of improving cotton is by "classing" the present miscellaneous crop into the so-called "even-running lots." Buyers like to get long-staple bales at short-staple prices, but do not forgo present profits in order to encourage the improvement of future crops that somebody else may buy. The commercial system provides no incentive for improved production.

The farmer is at liberty, of course, to raise better cotton if he chooses, but extra care and expense must be given, with no assurance of being able to sell at a higher price. Instead of gaining an advantage or of being encouraged to continue the planting of a better

variety, the progressive farmer at the end of the season may find himself making a forced contribution to an unjust system. Naturally, he loses interest in raising cotton of better quality, and goes back to ordinary "gin-run" seed or to the shortest and most inferior variety that promises a large yield.

There is no agricultural reason why any part of the American cotton belt should produce less than inch staple, nor is it an advantage to any interest that the production of inferior, short, and irregular staple should continue, but the inertia of the system must be overcome. If longer and more uniform staples are to be grown, they must sell at least as readily and as profitably as short staples. Since the farmer makes no use of cotton at home, but raises it only to sell, the quality of the fibre is of interest to him only as the price is affected. Better prices for better cotton are the only inducements that the farmer should be expected to consider. Preaching from any other text is sure to fall on deaf ears.

The present scarcity of superior fibre could be met most promptly and effectively by having more good cotton grown instead of wasting the resources of production by planting inferior cotton. The real obstacle is a defective commercial system, which undoubtedly could be changed without any great difficulty if the manufacturers had sufficient understanding of the conditions and needs. The problem, no doubt, is much the same in other countries as in the United States: to render production more efficient by improving the quality of the crop.

After two decades of investigation of cotton-breeding problems in the United States it is being recognised that the production of the best and most uniform fibre can be maintained only in communities that limit their production to a single variety of cotton, so that there shall be no mixing of different kinds of seed at the public gins or crossing of different kinds in the field. One-variety communities have been maintained for several years in the Salt River Valley of Arizona, where the practical advantages of the plan have been demonstrated and the commercial obstacles more clearly revealed.

Community production of better cotton in other regions might go forward rapidly if farmers were assured of better markets for good cotton than for short, mixed fibre. High prices may be expected to affect the quantity of cotton to be grown, but the quality will not be improved unless there is a distinct advantage in raising better cotton. So long as manufacturers are willing to take the present commercial system entirely for granted, and overlook its effect upon production, no prompt or general improvement is to be expected.

Lack of discrimination in buying from the growers is the weak point of the present system, not to be made good by paying all growers more for their cotton, but by paying more for good cotton and less for poor cotton. Discrimination in prices must be applied in the primary markets instead of the present careless and incompetent buying of "hog-round" lots at "flat" prices, which leads the farmer to produce the worst fibre instead of the best, because varieties with inferior lint often yield well or turn out high percentages of lint at the gin, and do not need such careful handling as the longer staples.

Not only the condition or "grade" of the cotton, but also the quality or "staple" need to be recognised while the cotton is still in the hands of the farmer. Outside of cotton markets it is seldom understood that the grades used in buying cotton from farmers have no relation to the essential textile qualities of length, strength, and uniformity of fibre, but only to incidental differences that result mostly from careless picking or from exposure to the weather. The system buys grades from the farmer, but sells staples to the manufacturer, getting discounts from the farmer and premiums from the manufacturer.

Discrimination could be applied honestly and to the best advantage on the farm before the cotton is picked. Uniformity of the fibre, which is an essential factor of quality and value for textile purposes, can be determined much more readily and definitely while the cotton is still in the field than after it is brought to the gin or passed into the bale. Field inspection of the plants shows readily and easily whether the stock represents a select, uniform variety or is mixed with plants that yield only short, inferior fibre, as most of the "off" plants do when a good variety is allowed to deteriorate through admixture or neglect of selection.

If the cotton is mixed and irregular in the field there is no chance that the farmer will have high-quality fibre to sell, although the average buyer could not determine the admixture from the bale samples. The careless farmer usually sells his cotton at the same price as his more careful neighbours, to say nothing of the dishonest farmer who deliberately grows a mixed field with 20 per cent., or even 50 per cent., of short cotton, but gets the long-staple price for his crop.

The quality of the fibre is affected also by cultural conditions of soil, season, and methods of handling the crop. Even on the same farm or in the same field inequalities of soil or treatment may result in cotton of very different textile qualities, which would be marketed in separate bales if adequate discrimination in buying made such precautions worth while to the grower. The careful discrimination of quality that should be applied in the field can be made good only in part by the elaborate mill [illegible] manufacturers [illegible] much waste and breakage [illegible]. Such losses, as well as costs of cleaning and combing processes, undoubtedly could be reduced to a great extent through more careful buying and the more careful growing and handling of the crop which discriminating treatment of farming communities would secure.[1]

Field-inspection buying may be considered as a new application of botanical knowledge, but the underlying facts have been established, and there is no reason to doubt that the talent applied in commercial sampling from bales could be used more effectively for determination of the quality of fibre before the cotton is harvested. Such a reform would give the commercial system a positive, constructive relation to the industry instead of the present negative, parasitic relation. Farming communities would turn at once to the production of fibre of better quality, to the general advantage of the cotton industry and the consuming public. No doubt the relation of prices to production has been overlooked because it is so simple and obvious, but a new approach is open to manufacturers through the organisation of one-variety communities. A strong department of commercial relations in the new Cotton Research Institute at Manchester would be a practical recognition of the principle approved by Sir George Watt: "The cultivator's interests are paramount."

O. F. COOK.

Fuel Research.

By PROF. JOHN W. COBB.

THE rising cost of coal will help to focus attention upon all such potential relief work as that of the Fuel Research Board, which has now issued its 1918–19 report over the signature of its director, Sir George Beilby. The report is of a comprehensive character, and gives evidence both of care in preparation and of a desire and competence to grapple in a scientific and effective manner with some of the more important problems with which the country is faced. The Board not only undertaking experimental work at a station established for the purpose at East Greenwich, and conveniently placed near a works of the South Metropolitan Gas Co., but is also concerning itself with inquiries conducted elsewhere into the thermal efficiency of open fires and cooking ranges, the economic position of pulverised coal, the cutting, winning, and utilisation of peat, and the sources of raw material for the production of power alcohol. The report also includes a reasoned account of the proceedings of the Board in the matter of the new gas standards which had been wisely referred to it by the Board of Trade and on which it has made recommendations. A survey of the national coal resources from the physical and chemical points of view is promised, this work having been taken over from the Coal Conservation Committee, which recognised the importance of such a survey, but, being without a staff, did not feel able to carry it out.

The equipment and lay-out of the experimental station at East Greenwich are described at some length. Stress is laid upon measures taken to allow of striking a correct thermal balance for each piece of plant employed, although it is no doubt recognised that the smallness of each unit would have to be taken into account in translating results into terms of large-scale practice. It is interesting to note that the position of water-gas as a heating agent for such purposes as the firing of the gas-retort installations is now so far established that the Board has felt justified in making blue-water-gas its standard fuel. Recent experience has demonstrated that the traditional restriction in the use of water-gas to operations requiring intense local heat was unnecessary.

Apparently the first purpose to which the experimental plant is to be put is the complete investigation of low-temperature carbonisation, concerning which so many conflicting statements have been put forward. This is a very legitimate inquiry, and the report justifies it (if any justification is needed), by insisting upon the wisdom of probing all possible sources of supply for the fuel oil on which the Navy and mercantile marine are becoming increasingly dependent. It is plain that Sir George Beilby approaches this process with some predisposition in its favour. He has himself made preliminary experiments upon it, and in an appendix to the report there is reprinted a contribution which he made to the discussion of the subject at the British Association meeting in 1913. The report displays a somewhat unfortunate tendency to rule out the carbonisation processes of the gas industry as being unlikely to produce larger quantities of fuel oil, because "present movement is all in the direction of obtaining the highest possible proportion of the total thermal units of the coal in the form of gas with a smaller consumption of coal per million thermal units distributed." Such ruling out is not justified, as a later qualifying clause admits. The further technical success of the gas industry would be expected to result in a large replacement of coal as a domestic and industrial fuel by gas, and although the thermal units carried by the gas from a ton of coal would increase, the margin for replacement is so considerable that the total amount of coal *gasified* would increase also. Moreover, it is unwise to assume that such developing processes as the distillation in vertical retorts of a descending stream of coal in an ascending stream of steam or other gas cannot be made a most effective and economical means of securing the maximum yield of volatile products, including tar oils if they are wanted. Most of the favourable "non-destructive" conditions claimed for low-temperature carbonisation may quite probably be secured in this way without the attendant disadvantages of that process as it has so far been described and worked. The whole matter is still *sub judice*.

The net commercial result of any carbonisation process is to a great extent dependent upon the relative market values of products, which change from time to time. From a thermal point of view, however, the movement towards obtaining a large proportion of the thermal units of the coal in gas is justified by the high thermal efficiency of gas in use, combined with the low thermal cost of production which can be made to attach to it. From the point of view of by-products, fuel oil has, no doubt, its importance, but it would be a mistake if sulphate of ammonia were to be deposed from its pride of place without due consideration, and it seems clearly to be established that low-temperature conditions are very unfavourable for the production of ammonia. It may be that national safety will be held to demand the working of a commercially unremunerative process, but, if so, the decision should be made with open eyes.

The results which Sir George Beilby, Prof. Thomas Gray (chief of the laboratories), and their staff are setting out to obtain in connection with the low-temperature carbonisation process will be of great interest to many who have been waiting for trustworthy data concerning it. The commercial success of low-temperature carbonisation on an extended scale is bound up with the creation of a demand for the soft coke or semi-coke which would be one of its main products. As compared with raw coal, this material, like any other coke,

would have the outstanding advantage of smokeless combustion, but its ash content would, of necessity, be higher. It would have the great disadvantage of crushing more easily than ordinary coke in all the processes of transference from the retort to the consumer, but would be correspondingly easier to ignite. Like both raw coal and ordinary coke, it would deliver potential heat units at a cheaper rate than they are supplied in gas. The question of efficiency in use remains, and the report deals benevolently with the efficiency obtainable from coal and coke in the most widely used domestic appliance—the open fire. It is set out that with an open fire, which has apparently a chance of regaining a lost reputation if it will only consent to provide a market for large quantities of soft coke, "probably 30 to 40 per cent. of the heat escapes completely, 60 to 70 per cent. being used in warming the room itself and the general fabric of the building."

On this point careful statement is advisable. In view of the comparative unavailability of any heat from the coal fire which is not given up to the room, it would be quite wrong to take 60 to 70 per cent. as being the thermal efficiency of the open fire, just as it would be wrong in the other direction to take the radiant efficiency of such a fire (about 25 per cent.) as the total efficiency. Comparative tests are probably best made on radiant efficiency, and it is not surprising to find that the tests made by Dr. Fishenden and quoted in the report are made on this basis. Dr. Fishenden's tests on coal and coke fires have been carried out at Manchester by the method worked out at the University of Leeds for testing the radiant efficiency of gas fires, with such modifications as were found necessary. The work has undoubtedly been carried out with care and skill, but it should be borne in mind that, on account of the varying condition of a coal fire during the course of a determination, the quantity and distribution of radiation from it cannot be measured with anything like the same degree of precision as with a gas fire. Dr. Fishenden does seem to be satisfied, however, that the radiant efficiency of the coke fire is higher than that of the coal fire, and, according to the report, "the radiant efficiency of coal fires of different types varies from 19½ to 25 per cent., while, with fires of low-temperature coke in the same grate and burning under the same conditions, this amounts to 31 to 34 per cent." It may be noted that the radiant efficiency of a modern gas-fire is approximately 45 to 50 per cent., but the report does not fail to point out that the real thermal advantage of the gas fire is much greater than would be indicated by any such comparison, because it can be used almost immediately at full efficiency for any period of time, great or small, this, of course, apart from any question of labour-saving and cleanliness. Cooking ranges were brought under test by Mr. A. H. Barker, and his reports are summarised in an appendix. "Mr. Barker lays stress on the extravagance in fuel involved by the necessity of heating the whole apparatus in the use of only one or possibly two of its appliances," and points out the further difficulty of obtaining high economy under ordinary working conditions because of the large excess of air employed.

It is plain that, whether coke or gas is used as a means of replacing raw coal for domestic uses, the smoke nuisance would be abated, and a section of the report given under the head "Air Pollution" shows this aspect of the fuel problem to be receiving attention from the Board. The pioneer work of Prof. J. B. Cohen (which should not be overlooked) was of great service in directing attention to the considerable quantity and evil effects of smoke in our atmosphere, and observations have since been multiplied by the Atmospheric Pollution Committee of the Meteorological Office, Dr. J. S. Owens, Mr. William Thomson, and others whose work is referred to in this report. The appointment of properly trained inspectors whose help and advice would be welcomed by industrial consumers of fuel is advocated, in addition to the establishment in every large works of an organised fuel control as the "only solid foundation on which to build more revolutionary or further-reaching methods of fuel economy."

It is pointed out usefully that soot from the burning of raw coal, ash and dust from the burning of coal or coke, and acid impurities derived from the sulphur contained in coal, coke, and unpurified gas, are all to be taken into account in a consideration of atmospheric pollution resulting from the use of fuel, and it may be emphasised that the liability to pour out large quantities of fine ash into the atmosphere is not to be overlooked in considering the advantages and disadvantages of pulverised fuel. The use of pulverised coal has not been developed in this country to the same extent as in America, and, therefore, although the Board is putting down a small plant in order to make experiments at East Greenwich, it has thought it advisable to secure full information upon the subject through a report made by Mr. Leonard Harvey after a special inquiry conducted in America. Mr. Harvey visited important installations and collected there the experiences and views of the leading consumers of pulverised coal. His report has already been issued separately. "The advantages of the method as an almost perfect means of burning coal must be weighed against the cost of producing and handling coal-dust and the difficulties which may have to be overcome in dealing with its ash."

Another special inquiry has been directed to the subject of peat. This work has been carried out mainly in Ireland, and has undergone vicissitudes, but a beginning seems to have been made, and reference is made to a paper, read before the Royal Dublin Society in March last, in which Prof. Purcell gave an admirable summary of the peat situation, not only in Ireland, but also in other countries. It is interesting to note, as indicating elasticity of method, that this paper will be printed as one of the special reports of the Fuel Research Board, and also that the help of the Department

of Scientific and Industrial Research has apparently been accorded for the production of an English translation by Prof. Ryan of Hausding's "Handbook on the Winning and Utilisation of Peat."

As regards fuel alcohol, the position is summarised thus: "It is obvious that until an estimate has been made of the possible resources for the production of alcohol within the Empire, and until their probable amount and the cost of using them have been ascertained, it would be useless to embark upon research on any extended scale into methods of production or utilisation."

The report, under the head "Gas Standards," gives a summary of the steps taken by Sir George Beilby and the Board from the time they were asked to advise on the subject by the Board of Trade, which recognised the complete inapplicability to modern conditions of gas standards as they had existed before the war. Conferences were held with those interested in the matter in different ways, and at a final conference resolutions were put and adopted which were forwarded to the Board of Trade, and constitute a new and much more rational method of regulating gas supply by statute. The central principle is that the consumer shall be charged with the potential thermal units supplied to him in the gas. The permissible percentage of inert constituents is limited by another resolution, although, of course, the temptation to pull "inerts" into the gas is removed now that they have to be distributed at the same cost as combustibles, but have not to be paid for. The gas undertaking can decide on the calorific value of the gas it intends to deliver, a power which should open the way for extensive technical development of the industry, and allow of the realisation of economies which have hitherto been rendered impossible by useless and out-of-date restrictions. The refusal of Sir George Beilby and the Fuel Research Board to accept any restrictions in this regard, however pertinaciously and dogmatically they were put forward, unless they could be justified by some adequate reason, has exemplified in a striking way the advantage of referring a matter of this kind to a competent technical authority. The choice of a new standard is a new degree of freedom, but, the choice being made, the gas undertaking is required to adhere very closely to it. Recognition is here given to the valid principle that unsatisfactory performance of a gas-using appliance is far more likely to be due to variations from the standard than to any lowness (or highness) in the standard itself. It is recognised that if the standard is materially altered the burners in consumers' appliances may need alteration, and the gas undertaking has to make the adjustment. "The calorific value of the gas is to be continuously measured and recorded by a recording calorimeter of a standard type to be passed by the London Gas Referees," and by this means it is hoped that the control of gas quality can be made much more effective than it has been hitherto.

Sir George Beilby has had under observation for some time the Simmance recording gas calorimeter with apparently satisfactory results, but the strain will come when legal penalties are dependent upon the accuracy (or inaccuracy) of this or any other form of recording gas calorimeter. Presumably, however, the possibilities of error will receive full investigation, and the successful working of so promising a scheme for the regulation of public gas supply will not be endangered by the imposition of any rigid system of testing which is not one of fully proved trustworthiness.

Use of Sumner Lines in Navigation.[1]

By CAPT. T. H. TIZARD, C.B., F.R.S.

THE Sumner line as a means of aiding in the navigation of ships has been in use for certainly seventy years, and is one of the best methods of obtaining the position of a ship at sea, for by its means both latitude and longitude can be obtained simultaneously without difficulty, and it has certain other advantages. In obtaining both latitude and longitude simultaneously, observations of more than one heavenly body are required, and the Greenwich time must be known accurately, as well as the approximate latitude. The altitudes of two or more heavenly bodies can be observed at twilight, both morning and evening, when the weather is clear, the horizon distinctly visible, and the stars are yet to be seen before the sky is lit up by the sun. It is possible, too, even without using the Sumner line, to observe in daylight meridian altitudes of Venus or Jupiter if they cross the meridian at least two and a half hours before or after noon, and occasionally both sun and moon are available during the day. In northern latitudes the pole star is always available in clear weather, at twilight, for observations for latitude, and one or two other stars for longitude, but if neither the pole star nor a heavenly object near, or on, the meridian is available for obtaining the latitude, Sumner's method affords a means of doing so.

Sumner's method briefly is as follows: If straight line be drawn from the centre of the earth to any heavenly body, at the spot where this line cuts the circumference of the earth, the altitude of that heavenly body will be 90°, which spot is named by Mr. Comstock the sub-polar point; a more appropriate name would be the zenith point—that is, the point on the earth's surface where the heavenly object observed would be in the zenith; and if circles be drawn on the earth's surface round this spot, with it

1 "The Sumner Line or Line of Position as an Aid to Navigation." By G. C. Comstock. Pp. vi+70. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 6s. net.

as a centre, those circles are really circles of altitude of the heavenly body; so that when an observer takes an altitude of a heavenly body he is on a circle of altitude, and his position be taken, and the resulting Sumner line should coincide in cutting the other two lines in, or close to, the spot already determined.

The second method of obtaining the Sumner

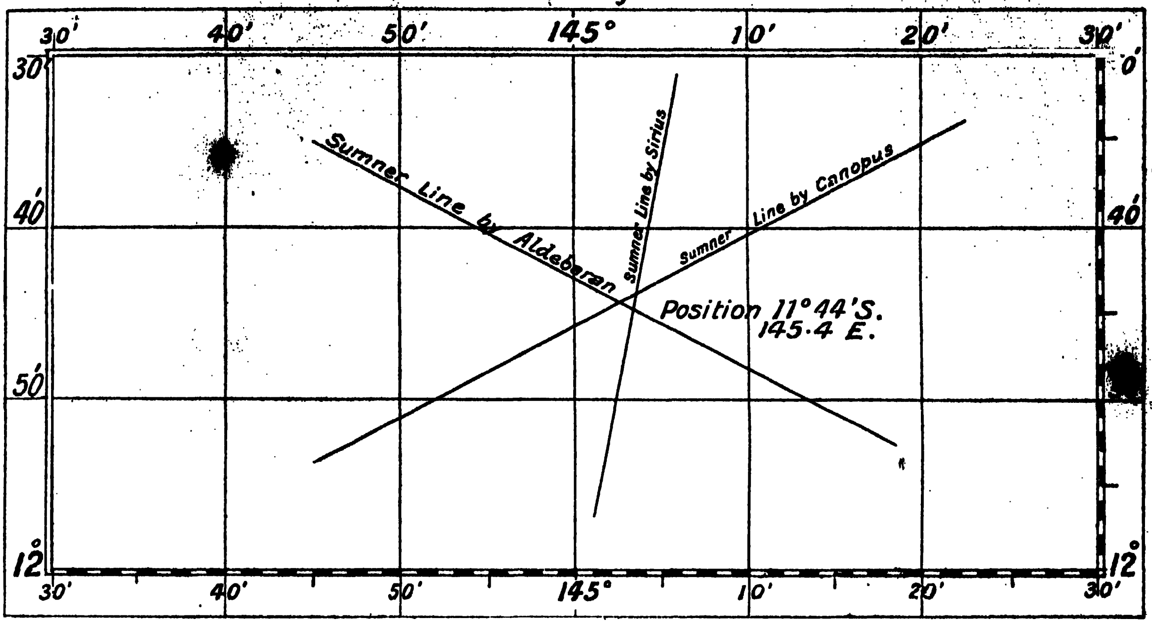

FIG. 1.

on that circle can be obtained by taking simultaneous altitudes of two heavenly bodies, or, in other words, of obtaining two circles of altitude which cut each other at a suitable angle, and the spot where they cut each other is the required position of the observer. The circles of altitude are of such a great radius that for short distances they are practically straight lines. There are two methods of obtaining the position of sections of these circles of altitude, or Sumner lines. In both it is necessary to know the exact Greenwich time, the approximate latitude, and the exact declination of the heavenly object. These are always available in a ship provided with a chronometer and a Nautical Almanac.

The first method is to assume two latitudes, one, say, 10 miles north, and the other 10 miles south, of the approximate position, and with each latitude, combined with the altitude and polar distance, to calculate the longitude, a process familiar to all navigators; then plot the two positions thus obtained and draw a line on the chart joining them, and the observer must be on that line. With observations of another heavenly body, and using the same latitudes, go through the same process, and the observer's position will be on the spot where the two lines cross each other. If it is very important to avoid error—as when sailing towards narrow channels through coral reefs, such, for instance, as the Raine Island passage through the Great Barrier Reef in Australia—observations of a third star can

line is to use only one latitude, and to calculate the longitude and the azimuth, or true bearing, of the heavenly body; then, as the circle of altitude, or Sumner line, is at right angles to the true bearing, already calculated, by plotting the

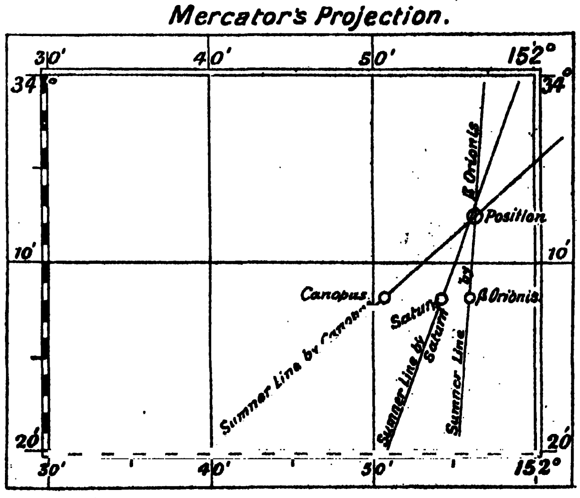

FIG. 2.

latitude and longitude and drawing lines at right angles to the true bearing, the position of the observer is where those lines cut each other.

The following examples illustrate the methods:

(1) On August 30, 1874, when H.M.S. *Chal-*

lenger was making for the Raine Island passage, observations were taken at 5 a.m. of Aldebaran, Sirius, and Canopus, and the latitude was assumed to be 11° 40′ S. or 11° 50′ S. Using these latitudes, the position of the Sumner lines was found to be as shown in Fig. 1, and the position of the vessel to be 11° 44′ S., 145° 4′ E.

(2). On June 13, 1874, observations were taken at 6 a.m. (to fix the position of a deep-sea sounding) of β Orionis, Canopus, and Saturn, the latitude being assumed as 34° 12′ S., the resulting longitude by β Orionis being 151° 56′ E., and its azimuth S. 86° 26′ E., the Sumner line therefore running N. 3° 34′ E. and S. 3° 34′ W. The longitude by Canopus was 151° 50′ 45″ E., and its azimuth S. 39° 18′ E., its Sumner line running N. 50° 42′ E., S. 50° 42′ W.; the longitude by Saturn was 151° 54′ 15″ E., and its azimuth N. 73° W., and the Sumner line by it running N. 17° E., S. 17° W. These lines are shown in Fig. 2, and the position of the sounding was lat. 34° 8′ S., long. 151° 56′ E.

But the Sumner line has another advantage. When only one heavenly body is visible, and, therefore, the exact position of the observer cannot be obtained, if with an assumed latitude the longitude and azimuth be calculated, and the resulting Sumner line be plotted on the chart, if this line runs in the direction of the port, or point of land, towards which the ship is sailing, by steering along the Sumner line the vessel will reach her destination. For instance, if when sailing towards the English Channel an observation of the sun be obtained in the forenoon, when its azimuth, or true bearing, is somewhere between south and east, the Sumner line will be between east and north; and if this line runs towards the Lizard or some other known point, by steering along this Sumner line a good landfall may be obtained.

Obituary.

Dr. F. A. Tarleton.

FRANCIS ALEXANDER TARLETON, who died on June 20, was born in Co. Monaghan in 1841. He was the youngest son of the late Rev. J. R. Tarleton, of the Established Church in Ireland, and received his earlier education from his father. At the age of sixteen he entered Trinity College, Dublin. He was in the same year as the late Sir Robert Ball, whom he defeated at the moderatorship examination in mathematics in 1861, taking also a junior moderatorship in logic and ethics. Elected to fellowship in 1866, and called to the Bar in 1868, he was for a time assistant to the professor of applied chemistry, and professor of natural philosophy from 1890 to 1901, when he was co-opted a senior fellow. From that time until a few days before his death he sat as an efficient member of the board of Trinity College. Dr. Tarleton held several college offices, including those of senior bursar, senior lecturer, and senior dean, the last being a sinecure—for its statutory duties have long since lapsed. As senior bursar he showed his qualities as a first-class financier. He was at one time president of the Royal Irish Academy, and a member of the Board of Irish Intermediate Education.

As professor of natural philosophy, Dr. Tarleton followed the traditions of his distinguished predecessors, Williamson, Townsend, and Jellett, in treating the subject from a strictly mathematical point of view. Although he had a considerable practical acquaintance with experimental science, he flatly ignored the judicial aphorisms of Francis Bacon, and, instead of treating mathematics as the handmaid of physics, he rather inverted the order, and almost succeeded in reducing hydrodynamics, elasticity, magnetism, and electricity to branches of pure mathematics.

The writer attended Dr. Tarleton's moderatorship and fellowship lectures about twenty years ago in hydrodynamics, elasticity, and the electromagnetic theory of light, and was struck with wonder at his extraordinary memory and accuracy. For two and a half hours he would write down long and intricate calculations without the aid of any notes. Sometimes a student at the end of an hour would ask to be allowed to leave in order to attend a lecture in experimental science or history or other subject, and Dr. Tarleton would say with a snarl and a grimace (covering a heart full of humour and humanism): "Waal, if you prefer that *abominable* subject to mathematics, you are welcome to leave, and we're glad to get rid of you."

The last time the writer spoke to him, Dr. Tarleton expressed his intense dislike of Einstein's theory of relativity. He held that the Newtonian and Kantian conceptions of space and time are good enough to explain all possible phenomena, if sufficient mathematical ingenuity is shown, and he placed relativism in the same category as Bolshevism.

Dr. Tarleton wrote the following papers:—"On the Solid of Revolution having a Given Volume which experiences the Least Resistance in Passing Through a Medium," "Chemical Equilibrium," "Deductions from MacCullagh's Lectures on Rotation," "The Foundations of the Science of Number," "Notes on Crystallography," "Geometrical Proofs of Some Properties of Conics," "The Harmonic Determinant," "Laplace's Coefficients," and "A Problem in Vortex Motion." His two books "Dynamics" (written in conjunction with Williamson) and "An Introduction to the Mathematical Theory of Attractions" are first-class text-books of their kind. The latter contains a chapter on Maxwell's electro-magnetic theory of light.

R. A. P. Rogers.

GEOLOGISTS will regret to learn that DR. WHEELTON HIND died on June 21. Dr. Hind was born at Roxeth, near Harrow, in 1860, and graduated in medicine and surgery in the University of London, also gaining the fellowship of the Royal College of Surgeons. He began practice at Stoke-on-Trent more than thirty years ago, and soon occupied a prominent place among the surgeons of North Staffordshire. His recreation from the first was field-geology, which suited both his athletic activity and his eagerness for purely scientific work. His early studies coincided with the movement initiated by Lapworth and others for the more exact correlation of stratified rocks by a very detailed study of their contained fossils; and Dr. Hind proceeded to apply this new method of "zoning," as it was termed, to the Carboniferous rocks of the neighbourhood in which he resided. His success in discovering the regular order in which the different assemblages of fossils occurred in Staffordshire and Derbyshire gradually led him further afield. He co-operated with members of the Geological Survey, and after extended researches in Lancashire and Yorkshire he joined Mr. J. Allen Howe in 1901 in contributing to the Geological Society of London a fundamentally important memoir on the classification of the Lower Carboniferous rocks of north-central England. Dr. Hind also recognised that, for the purposes of the stratigraphical geologist, the species of Carboniferous Mollusca needed more exact definition than had previously been attempted, and he devoted much labour to adding two finely illustrated monographs on the subject to the series published by the Palæontographical Society. Some of the molluscs proved to be of value for recognising the various seams of coal in the Staffordshire coalfield, and in 1903 Dr. Hind and Mr. J. T. Stobbs prepared an illustrated wall-chart of them for the use of the practical miner. On the outbreak of war in 1914 Dr. Hind joined the Army as a gunner, and took part in some engagements in France; but he was afterwards employed as surgeon, and attained the rank of lieutenant-colonel. He received the Lyell medal from the Geological Society of London in 1917.

THE death, at the age of seventy-eight, of MR. JAMES KENNEDY is a serious loss to Oriental studies. The son of an Indian missionary, Mr. Kennedy was employed in the Civil Service of India from 1863 to 1900. After his retirement he was a leading figure in the Royal Asiatic Society, serving as treasurer until illness compelled his resignation, and winning the respect of his colleagues by his learning, business capacity, and kindliness of nature. He was one of those patient workers who are always collecting materials, hoping for new light on difficult problems, and thus he failed to accomplish his projected task, a history of the relations of Indian culture with those of Nearer Asia. He contributed to the Proceedings of the Royal Asiatic Society several valuable monographs, the most important being devoted to the early trade intercourse of Babylonia with India, the cults of Krishna, and the Aryans, the last published only a few months before his death. Though some of his ingenious speculations failed to meet with general acceptance, it is much to be regretted that he failed to accomplish the work to which his life was devoted.

LAST week there died in Paris, in his eighty-second year, M. ADOLPHE CARNOT, a member of the Academy of Sciences and of the Legion of Honour. M. Carnot was the grandson of M. Lazare Carnot and the son of M. Hippolyte Carnot, the Minister of Public Instruction in the Provisional Government of 1848. President Sadi Carnot was his elder brother. For many years M. A. Carnot held a professorship at the École Supérieure des Mines, and was afterwards its honorary director. He was also Inspector-General of Mines in France.

M. Carnot's scientific reputation rests chiefly on his contributions to analytical methods, and his treatise on the analysis of mineral substances is the standard French work on this subject. It comprises a detailed account of the occurrence, properties, reactions, methods of separation, and analysis of all the metals, including the rare metals, which are very fully described. The information given with reference to the rare metals is based largely on his own original work. He was a frequent contributor to the *Annales des Mines*, and published papers on methods of determining phosphorus, silicon, potassium, iodine, chlorine, bromine, vanadium, molybdenum, chromium, etc. In 1900 there appeared his important joint paper with Goutal on the verification of compounds existing in iron and steel by using reagents with which to dissolve out certain of the constituents. This paper is one of the best that have appeared on this subject.

WE regret to have to record the death of MR. HAMMERSLEY HEENAN, which took place on June 17. Mr. Heenan was born in 1847, and had been a member of the Institution of Mechanical Engineers since 1875, and of the Institution of Civil Engineers since 1876. An account of his career appears in *Engineering* for June 25. At seventeen years of age he went to India and spent about fifteen years in the Public Works Department. Mr. Heenan returned to England in 1880 and founded the firm of Heenan and Froude, Ltd., of which he was chairman and managing director until his retirement two years ago. The firm is principally engaged on bridges and structural work generally. Among its undertakings is the Blackpool Tower. During the war Mr. Heenan rendered great service both in his personal capacity and in applying the resources of his works to the manufacture of munitions.

THE death is announced of DR. J. H. HYSLOP, the founder of the American Society of Psychical Research.

Notes.

THE report of the Advisory Committee on Civil Aviation (Cmd. 770, price 2d.), dealing with the question of Government assistance for the development of civil aviation, will be read with interest by those who are concerned in the commercial future of the aeroplane. The report considers at length the present position of civil aviation and the results which have been achieved, and reaches the conclusion that as regards both the progress of commercial flying and the maintenance of a healthy aeronautical industry the indirect assistance given in the past is insufficient. Definite proposals for direct assistance are made. It is suggested that such assistance should be limited to a sum of 250,000l. within the two financial years 1920–22, and calculated on a basis of 25 per cent. of the total revenue of the aviation companies concerned, without differentiation as to the nature of the load carried by the machines. "Approved" routes are suggested: (a) London to Paris, with extensions; (b) London to Brussels, with extensions; and (c) a route such as England to Scandinavia, giving opportunities for the development of seaplane and "amphibious" machines. Air-Marshal Sir Hugh M. Trenchard criticises this policy in a minority report. He considers that the Committee is not justified in its assertion that commercial aviation has hitherto been a failure, and expresses the view that there has not yet been sufficient time for the advantages of aerial transport to be appreciated widely and so to create the necessary demand. He further considers the policy of subsidies to be fundamentally unsound, and thinks the money would be better spent in encouraging the design of experimental machines and in helping forward general research on aeronautical questions—a view for which there is much to be said. Assuming the subsidy to be granted, however, Sir Hugh agrees with the mode of application suggested by the majority report.

THERE has just appeared the second interim report of the Water Power Resources Committee, which gives effect to the extended terms of reference it received in October last, viz. to take into consideration the steps necessary to ensure that the water resources of the country are properly conserved and fully and systematically used for all purposes. The Committee recommends that there should be established, by Act of Parliament, a controlling Water Commission, having jurisdiction over England and Wales, upon which should be conferred certain statutory powers and duties relative, *inter alia,* to the compilation of proper records of the water resources and water requirements of the country, the allocation of these resources, the adjustment of existing anomalies and hardships, and the reconciliation of conflicting interests. Such a body would assist Government Departments concerned in the uses and control of water, would advise Parliamentary Committees before which Water or Water Power Bills may be heard, and generally would act as consultants and technical specialists to the Government in regard to questions within their purview. They would also promote and initiate legislation for securing the development of rivers as a whole from source to mouth. The Committee recommends that further powers should be conferred on the Ministry of Health and other Government Departments to make orders authorising uncontested schemes of improvement. As regards its primary investigation, the Committee reports that there are several parts of Great Britain in which exist large sources of water power capable of development, but that it will deal more fully with this section of its inquiry in its final report, as well as with amendments required in the law in regard to pollution, underground water, and kindred subjects.

THE Department of Overseas Trade, in promoting the Empire Timber Exhibition at the Holland Park Skating Rink (July 5 to 17), has aimed at bringing under the notice of the British timber trade the various kinds of timber grown within the Empire. The exhibition will be fully representative of the timber-growing countries of the Empire, and should be of much interest and value.

THE annual meeting of the Somersetshire Archæological and Natural History Society will take place on July 20–22, and an interesting programme has been arranged. On the opening day, at Bridgwater, the new president, Mr. A. H. Thompson, will deliver an address on "Medieval Building Documents, and What We Learn from Them." In the evening of the same day Mr. A. F. Major will read a paper entitled "The Geography of the Lower Parrett in Early Times and the Position of Cruca." On July 21 a lecture will be given by Mr. H. Corder on "Rambles round Bridgwater." In addition, there will be many excursions to places of interest. Further particulars of the meeting can be obtained from Mr. H. St. George Gray, Taunton Castle, Taunton.

THE DUKE OF CONNAUGHT on Thursday last paid a visit to the Royal College of Surgeons of England and received the diploma of an honorary fellow of the college.

THE RIGHT HON. H. A. L. FISHER and Sir James G. Frazer have been elected fellows of the Royal Society, under the statute governing special elections, on the grounds of their having "rendered conspicuous service to the cause of science."

AT the meeting of the Royal Society of Edinburgh on Monday, June 21, the following were elected foreign honorary fellows:—William Wallace Campbell, director of the Lick Observatory; Yves Delage, professor of zoology, Faculty of Sciences, Paris; Hendrik Anton Lorentz, professor of physics, Leyden University; Alfred Gabriel Nathorst, Stockholm; Ch. Emile Picard, perpetual secretary, Academy of Sciences, Paris; Charles Richet, professor of physiology, Faculty of Medicine, Paris; and Georg Ossian Sars, formerly professor of zoology, Christiania, and Director of Norwegian Fisheries.

MEDALS have been awarded to the following by the Council of the Royal Society of Arts for papers read before the society during the past session:—J. W.

Pearson, "The Seed Crushing Industry"; S. Preston, "English Canals and Inland Waterways"; Sir J. Currie, "Industrial Training"; Air-Commodore E. Maitland, "The Commercial Future of Airships"; Sir W. S. Meyer, "The Indian Currency System and its Developments"; A. Howard, "The Improvement of Crop Production in India"; Sir F. Watts, "Tropical Departments of Agriculture, with Special Reference to the West Indies"; and Sir J. Cadman, "The Oil Resources of the British Empire."

THE Riberi prize of the Academy of Medicine of Turin has been awarded to Dr. G. Vanghetti for his researches on amputations and kinematic prostheses.

MAJOR KENELM EDGCUMBE has been elected chairman of the National Illumination Committee of Great Britain in succession to Mr. A. P. Trotter. A meeting of the International Illumination Committee is to be held in Paris next year to discuss technical subjects.

A MONUMENT to Wilbur Wright is to be dedicated on July 18 at Le Mans, France, near which town he carried out many of his aeronautical experiments.

THE annual meeting of the Research Defence Society was held on June 23, when an admirable address was given by Col. McCarrison on "Vitamines in their Relation to Health." Col. McCarrison spoke with authority; he made clear the facts already proved, and the intricacies of the study of vitamines. It is strange now to recall the old teaching about the "constituents" of our food; the proteins and the fats and the starches; the old South Kensington exhibits of an apple or a mutton-chop analysed down to half a dozen phials of chemicals, of water, and of "ash"; but not a word said of these potent and subtle vitamines which "animate the whole" and safeguard us against rickets and scurvy and beri-beri and epidemic dropsy. After the meeting Dr. and Mrs. Mellanby showed specimens of the results which they have obtained in this field of research, especially in the relation of vitamines to the growth of the bones and to the development of the teeth. The society's annual report speaks of increased activity in good educational work. The Jenner Society has become affiliated to the Research Defence Society, and this is a move in the right direction. The Research Defence Society has lately published an address by Sir Walter Fletcher on the work of the Medical Research Council, and is about to publish an essay by Sir David Bruce on tetanus and the use of tetanus antitoxin.

SIR CHARLES TOMES has presented to the museum of the Royal College of Surgeons of England the entire collection of microscopical preparations made by himself and also by his father, the late Sir John Tomes, during their investigations into the structure and comparative anatomy of the teeth. In this important donation are included the preparations—many of great beauty as well as of scientific worth—on which memoirs published in the Philosophical Transactions and Transactions of the Odontological Society were based. The gift thus made is to be known as the Tomes Collection, and will be accessible to all who are making a study of the comparative anatomy and microscopical structure of the teeth of vertebrate animals.

AMONG the worked flints collected from the ploughed fields of Norfolk and Suffolk Miss Nina F. Layard has lately observed several with well-defined finger-grips, which she describes in the latest part of the Proceedings of the Suffolk Institute of Archæology (vol. xvii., part i.). The implements are beautifully illustrated by photographs, showing how they are adapted by chipping for holding in the hand. They include both scrapers and borers, and one seems to be suitable for cutting hides. The age of the implements is undetermined, and Miss Layard compares them with certain scrapers obtained by the late Dr. Sturge from Luxor, Egypt. She also points out that the North Alaskan Eskimos at the present day carve finger-grips in the wooden or bone handles in which they fix their stone scrapers.

THE problem how to make philology interesting has been solved by Sir George Grierson in two papers on the Indo-Aryan vernaculars reprinted from the Bulletin of the School of Oriental Studies. The Aryan languages cover, roughly speaking, the whole of the northern plain of India, penetrating in the case of the Pahári dialects into the lower ranges of the Himalayas, while closely related to them is another group of tongues in the mountainous country lying south of the Hindu-Kush, which are here styled the Dardic or modern Pisácha languages. The most important result of the Philological Survey is that the Indo-Aryan vernaculars fall into three groups: the midland, occupying the centre of the great northern plain; the outer in a band on the west, south, and east; while between these lies the intermediate group representing the former shading into the latter. These groups of tongues are obviously the result of successive invasions or the peaceful introduction of foreign cultures. The pressing problem at present is how to combine the philological with the ethnological evidence, and Sir G. Grierson's papers are a valuable contribution to the solution of it.

MR. W. E. HEITLAND published in the *Journal of Roman Studies* (vol. viii., part i.) an elaborate, fully documented article on the conditions of agriculture in Italy in Imperial times. He specially deals with the question whether Italy furnished a large number of farmer emigrants to raise and maintain provincial agriculture. He finds that the evidence does not favour such an emigration. One of the most pressing anxieties of the Emperors was to maintain a corn supply from Egypt and other African regions. But for the development of this industry native African farmers would be best qualified. Therefore, while we are entitled to assume that the Emperors were anxious to protect their *coloni* from the oppression of dealers with the connivance of corrupt officials, we ought not to base far-reaching theories of State-assisted emigration on the occurrence of a few Italian names in provincial inscriptions, the authors of which may not have been themselves *coloni*.

INFLUENZA was persistent this year in London for seventeen weeks from February 7 to May 29, the deaths from the disease, according to the returns of the Registrar-General, numbering 20 or more each week. For the previous fifteen weeks, from

October 15, 1919, to January 31, the deaths in London had ranged irregularly from 12 to 24. The return for the week ending June 12 gives only 13 deaths in London due to the disease, and in the preceding week the deaths were only 19. For the seventeen weeks ending May 29 the average deaths per week numbered 59, and in ten previous epidemics out of a total of twenty-eight since 1890 this number was exceeded, the highest weekly average being 500 in the epidemic of 1918–19, which lasted thirty-one weeks; the next highest was 171 in the epidemic of 1891, and 162 in 1892. The maximum number of deaths in a single week in the recent epidemic was 131, whilst in that of 1918–19 the number was 2458, the next highest maximum being 506 in 1892 and 473 in 1895. Of the twenty-eight epidemics since 1890 only two have embraced the summer months, those occurring in 1891 and 1918. The age incidence of the last three epidemics has differed widely from all others inasmuch as the active and able-bodied, aged between twenty and forty-five, have suffered most severely, although the attack, which has apparently now abated, was less marked in this respect than the two epidemics of 1918 and 1918–19.

Medical Science: Abstracts and Reviews for June (vol. ii., No. 3) contains among its articles a review of the subject of tuberculosis, particularly in connection with the war. Tuberculosis only slightly increased in France and England during the war, and mainly among young women in industry, whereas, in Belgium, Germany, and Austria, all classes of the community suffered and to a rapidly increasing extent. The principal causative factor for this difference appeared to be that of food.

In recent years the development of genetics has been marked by the establishing in various countries of a number of new scientific journals dealing with this rapidly growing subject. The latest addition to this list is *Hereditas*, the first number of which we have just received. It is issued by the Mendelian Society of Lund, Sweden, the president of which, Prof. H. Nilsson-Ehle, is well known for his breeding experiments with wheat. The journal will appear three times annually so far as possible, making a volume containing about 350 pages. The contributions are to be published in English, German, or French, and the subscription is 25 Swedish crowns per volume. The first number includes a study of the resistance of wheat to the nematode Heterodera and its inheritance, by Nilsson-Ehle; the hereditary transmission of deaf-mutism, by Lundborg, and of hereditary tremor, by E. Bergman; the rate of pollen-tube growth in Œnothera and its possible effect on inheritance-ratios, by Heribert-Nilsson, as well as studies of colour inheritance in peas and poppies, chlorophyll factors in the onion, and bud-sports in wheat. The new journal, which thus includes in its range the study of human as well as plant and animal material, will be a welcome channel of publication for the growing Scandinavian school of geneticists, and will take its place among the standard journals on this subject.

In the Reports of the South African Museum for 1918 and 1919 Dr. L. Péringuey records some new facts relating to the Strand-loopers. In a cave-shelter a slab-painting was found above the kitchen-midden material and beneath a stalactitic column. Skulls in the midden were filled with gypsum. The geological conditions indicate that these formations must have taken a long time to produce—a longer lapse than is usually accepted. "If we take into consideration the conclusions of Shrubsall, that Strand-looper skulls differ materially from the Hottentot or so-called Bush races, I am justified, I think," says Dr. Péringuey, "in claiming for the Strand-looper branch of the 'San' that occupied at one time the southern littoral of the former Cape Colony, not only a mode of culture more primitive than that retained by any living human race, but also a greater antiquity than for any other living African race." From the South-West Protectorate was obtained, and is figured in the Report, a rock-graving on which hoofs of animals and reduced representations of human feet had been produced by picking. Such gravings may, perhaps, denote places where the Bush people had found game. These are only a few of many interesting discoveries mentioned in these Reports.

The Smithsonian Institution has a custom, which we commend to the British Museum, of publishing each year an illustrated account of its explorations and field-work. The report for 1919, just to hand, contains narratives and illustrations that might well stir the enthusiasm of the American public and lead to donations for similar purposes. Where so much is of interest to astronomer, anthropologist, ethnographer, geologist, and zoologist, we should be hard put to it to make a selection did we not find some notes by Mr. C. M. Hoy on the extermination of the Australian native fauna, to which the attention of British naturalists should be directed. "The greatest agent working towards the extermination of the native animals is the fox; next come the cattle and sheep men, who distribute poison by the cartload in the effort to reduce the rabbits. This has also caused or helped to cause the extermination of some of the ground-inhabiting birds. Another great agent is the bush-fires which sweep over the country. These are often lit intentionally in order to clear out the undergrowth and thus increase the grass. . . . The country at Bulliac is a good example of what the cattleman will do in a few years' time in killing off and burning the timber, and the consequent destruction of animal life. . . . The extermination of the native mammals has apparently gone much farther than is generally thought. Many species that were plentiful only a few years ago are now almost, if not altogether, extinct. Diseases have also played a great part in the extermination. The native bear died in thousands from a disease which produced a great bony growth on their heads. A mysterious disease also spread through the ranks of the native cat, *Dasyurus viverrinus*; the domestic cat also played a great part in their extermination. Even adult specimens of Dasyurus were often dragged in by the family cat. . . . There are very few game laws in Australia, and no one gives any attention to the ones that are in order."

THE greater part of a skeleton of the giant extinct marsupial Nototherium has lately been found in Mowbray Swamp, Tasmania. The skull and the limb-bones of the left side are described as well preserved, and are especially important for comparison with the numerous scattered remains of the same animal discovered in the Pleistocene deposits of Australia. The skeleton of Nototherium is less satisfactorily known than that of the allied Diprotodon, of which many specimens were found in Lake Callabonna, South Australia, about twenty-five years ago.

WE have received a copy of vol. v. (1918–19) of the Journal and Proceedings of the Royal Society of Western Australia, from which we learn that this society makes steady progress in membership and in the value and importance of its publications. The papers deal mainly with Western Australian problems. Prof. W. G. Woolnough writes on the physiographic elements of the Swan coastal plain, adding several details that have been overlooked in more general accounts. An important historical paper is one by Mr. J. S. Battye on the early colonisation of Western Australia. Mr. W. A. Saw contributes a paper on town-planning in Australia. His paper is noticeable for a number of well-chosen illustrations showing good and bad planning in various Australian towns.

M. EMILE BELOT, whose artificial volcanoes were recently mentioned in NATURE, vol. civ., p. 575, has published a work on "L'Origine des formes de la Terre et des Planètes" (Paris: Gauthier-Villars, price 14.40 francs). While holding that the earth and the moon developed from a state of luminous vapour of nebular origin, the heat of this vapour not being due to mere contraction, he points out, on the analogy of novæ, that the intensely heated stage may have lasted only a few months, while other successive changes, such as those when rains of chlorides fell upon a warm surface, may have occurred during the first few years of terrestrial evolution. We cannot here quote the figures by which M. Belot argues that the first waters would condense in the primitive atmosphere, owing to its high pressure, at the temperature of 364°; it is sufficient to mention that, on similar numerical reasoning, he shortens the interval between the first rainfall (Antarctic) and the middle of the Carboniferous period to less than ten million years. The tectonics of the crust are discussed with the aid of simple but suggestive diagrams, and the frequent reversal of views now popular will certainly encourage thought.

AMONG the handsome series of Professional Papers issued by the U.S. Geological Survey in these years of turmoil we may note one by Mr. E. de K. Leffingwell (No. 109) on "The Canning River Region, Northern Alaska." Its description and illustrations of soil and vegetation above permanently frozen ground, or above a subsoil consisting almost entirely of ice, are of wide interest in lands in which such conditions once prevailed. The author uses the term "ground ice" for bodies of ice in frozen ground, which involves confusion with what has always been known as ground ice ("anchor ice" is preferred by Mr. Leffingwell) in rivers or in shallow seas. In most of the areas in which underground ice has been recorded, the downward limit of seasonal thawing is less than 7 ft., 3 ft. being the rule. The author shows, however, that this ice is a product of surface-thawing, water penetrating downwards and adding to the frozen masses at the present day. Underground ice will form wherever the mean annual temperature is some 4°–6° C. below freezing point. The author makes a strong case for his view that very large continuous ice-masses, with occasional inclusions of earth, like those of the New Siberian Islands, may arise from the growth year after year of ice-wedges originating from surface-cracks.

ON May 27 Mr. B. S. Gossling read an interesting paper on "The Development of Thermionic Valves for Naval Uses" to the Institution of Electrical Engineers. He gives first a history of the introduction of the thermionic valve into naval radio-telegraphy, laying stress on the use of Langmuir's formulæ for the value of the electron current as a guide to the numerical design of valves. To old-fashioned electricians the formulæ, which are numerous, are very uninviting. The physical dimensions on both sides of the equations appear to be quite different, and the continual introduction of the voltage to the power 1·5 is very puzzling. We think that the time has now come when the definitions of the fundamental quantities should be made more rigorous, and symbols should be used for the various quantities which show their physical dimensions. In the paper the successive stages of the approximations which were adopted in the calculation of the characteristics of valves are recorded. The final result shows that the observed behaviour of a high vacuum valve can to a first rough approximation be accounted for in terms of known physical laws. Many ingenious tests are described. The method adopted, for instance, for estimating the vacuum in a valve while still on the pump is to have a special vacuum tube attached to the apparatus and measure the width of the "cathode dark space." The paper gives a good idea of the immense amount of work done on the valve by physicists and engineers during the war. The variations of the thermionic properties of the valves which were so puzzling and annoying a few years ago have now been brought within bounds, and a rough standard specification for their production is given. Unfortunately, sufficient information to enable rigid life test clauses to be made is not yet available. It is a great step forward, however, that even a rough specification can be given.

BULLETIN No. 2 for 1920 of the Classe des Sciences of the Royal Academy of Belgium contains a communication from Messrs. J. E. Verschaffelt and R. Crombez on the anomalous dispersion of methyl-violet, fuchsine, and paranitrosodimethylaniline. The authors use the method of Soret, which Wood also adopted, which depends on the division of a glass trough with parallel surfaces into two parts by a glass partition extending from one corner to the opposite one. One of the prismatic troughs thus formed is filled with a solution of the material the dispersion of which is to be inves-

tigated, and the other with the solvent alone. Owing to the opposing action of the two prisms the dispersion of the solvent is thus eliminated, and the anomalous dispersion of the solute observed directly. By this means the authors have determined the indi of refraction of the materials as follows:—Methyl violet for wave-length 6712, 2·52; 6497, 2·43; 4455, 1·23; and 4227, 1·45. For fuchsine 6712, 2·21; 6497, 2·41; 6170, 2·63; 5857, 2·78; and 4227, 1·19. For paranitrosodimethylaniline 6497, 1·74; 6170, 1·78; 5857, 1·81; 5603, 1·85; and 5270, 1·93.

In the course of an article in *Engineering* for June 18 on the Birkenhead shipyard and works of Messrs. Cammell Laird and Co., Ltd., reference is made to the original generating stations which supplied the whole of the power for the works. The original station was equipped entirely with gas engines supplied from a Mond plant, which also supplied gas to the furnaces in the platers' and other shops. The ten gas engines were of varying sizes, and had a total capacity of 2500 kw. This gas station has done good service, but the large number of comparatively small gas-driven units has resulted in a considerable maintenance charge. There has also been difficulty at times during the war in obtaining suitable fuel for the producers. These conditions, combined with a growing demand for power, have resulted in a decision to shut the gas station down altogether, and to transfer all power generation to the new turbine station. The matter is of some interest in view of the controversy on fuel economy, and illustrates the fact that there are points other than mere economy of fuel to be taken into consideration by large power-users.

We are asked to state that the Research Association of British Rubber and Tyre Manufacturers has secured laboratory accommodation in the Chemistry Department of University College, Gower Street, W.C.1.

We regret to learn from an inset announcement in the current issue of the *Scottish Naturalist* that, notwithstanding that all editorial work in connection with the journal is rendered gratuitously, there was a loss on the year's working, which, however, has been generously met, and that in consequence of the continued increasing cost of production there is a possibility of the magazine ceasing to exist. We trust that this contingency will be averted, for our contemporary has performed valuable services to Scottish natural history for the lengthy period of fifty years. A largely increased subscription list would probably save the situation, and the publishers, Messrs. Oliver and Boyd, Edinburgh, will be glad to have the names of all who will help in the way suggested to keep in circulation this useful scientific periodical.

The latest catalogue (No. 188) of Messrs. W. Heffer and Sons, Ltd., Cambridge, gives particulars of upwards of 1900 second-hand books ranging over a number of subjects. There are sections devoted to science and mathematics; folk-lore and mythology; archæology; India; Ceylon; China, Japan, and the Far East; Turkey, etc. The catalogue, which will be sent free upon request, is worthy of perusal.

Our Astronomical Column.

Tempel's Second Periodic Comet.—The only additional information that has come to hand about this comet is that it was of magnitude 11 at the end of May. It should be of magnitude 9 or 10 in July, and therefore visible in moderate instruments. Accurate observations of position are badly needed, as very few were obtained at the last apparition in 1915. The period of this comet ($5\frac{1}{4}$ years) is the shortest known except that of Encke. Observations were secured in 1873, 1878, 1894, 1899, 1904, 1915, and 1920. The following approximate ephemeris is for Greenwich midnight:

	R.A. h.	S. Decl.	Log r	Log Δ
July 6 ...	23 14 51	7 17	0·1216	9·6962
14 ...	23 39 41	8 59	0·1216	9·6791
22 ...	0 2 40	11 5	0·1236	9·6685
30 ...	0 22 24	13 27	0·1274	9·6636
Aug. 7 ...	0 38 50	16 1	0·1330	9·6650

Denning's Comet of 1881 and a Meteoric Shower.—The Rev. M. Davidson has recently made some interesting computations of the dates and radiant points of certain comets if they originate meteor showers. Among these, Denning's comet of 1881 indicates a radiant on August 4 at 303°–10° about 3° N. of α Capricorni. For many years a prominent shower of slow, bright meteors has been visible from this point at the end of July and the early part of August, and it is quite possibly connected with the comet named. It was well seen in 1900 and 1902, as well as in 1908 and 1916. The comet probably returned in 1899, 1907, and 1916, though it escaped observation, and the next return should occur in 1925 if the computed period of about $8\frac{3}{4}$ years is correct. There are, however, meteors every year from this shower in Capricornus, and it should be specially looked for during the period from July 25 to August 8.

Capture Orbits.—Text-books on astronomy frequently contain a good deal of speculation on the possibility of capture of comets and satellites; we may quote as instances the Leonid meteors, supposed to have been diverted by Uranus from a quasi-parabolic orbit into an ellipse of short period, and the numerous comets of the Jovian family, on which Jupiter is presumed to have exerted a similar influence. In these cases the perturbing planet made the capture, not for itself, but for the sun. Capture of the former sort, in which the planet retains the captured body as a satellite, can apparently take place only with the aid of a resisting medium, in which case we must date the event in remote ages.

Little research of an accurate numerical character has hitherto been carried out on the subject. Prof. L. Becker contributes two papers to *M.N.* (vol. lxxx., No. 6), in which he shows that a star approaching a binary system may in certain cases suffer capture, while one of the original pair may be expelled from the system. He then points out that approaches would be more frequent in the direction of relative motion of the two star-streams, and by analysis of the distribution of the major axes of the orbits of binaries obtains a result in fair conformity with the theory. The research is made more difficult by the fact that there are two possible positions of the plane of a binary orbit. In a few cases (notably in the systems of Sirius and α Centauri) the spectroscope has decided which of these positions is the correct one. There are probably several other systems in which the spectroscope is capable of giving a decision. Observations of this kind are very desirable wherever they are possible.

Education in the New Era.

IN addresses given in Leeds last February Mr. F. W. Sanderson, headmaster of Oundle School, very boldly faces the root of the evil in existing educational systems as it is felt in the school, and advocates radical reconstruction upon new lines. His view is that schools should be altruistic in their aims and methods and be based on service and co-operation rather than on competition. They exist solely to aid and enrich the life of the people. Traditional methods based upon public-school models accentuate the anti-social spirit of competition and damp down co-operation, whereas the schools of the country ought to be the source from which the transfiguring and transforming spirit of the age is breathed through the thoughts of men. A school is a microcosm, and its subject-matter is to be found, not in books, but in the world around it, of which it itself should be an idealised model upon a small scale. It should concern itself with the tragedies of undeveloped talent, the slow decay of the faculties of masses of men caused by their employment in industry, and the sullen mental stupor that, after the violent revolutionary period of youth, brings peace on an animal level. For the schools are concerned with similar problems. The elevation of the submerged, the bringing back into the stream of school-life of the weak, and the raising of the general average are even more important there than the provision of the fullest opportunity for talent and ability. So is it in the national life. We are presented with a vision of spacious halls and galleries, workshops, laboratories, gardens and fields, art-rooms, libraries, and museums for children to learn in instead of in stuffy class-rooms, by doing, making, inquiring, and co-operating rather than by the preparation for interminable examinations, which suit better those of the possessive and dominating order, of whom the world is growing so tired.

The policy of leaving dull, bread-winning drudgery unredeemed in the state it is, and concentrating upon the cultivation of the artistic and literary faculties of the workers in enlarged periods of leisure, can only have the effect of making the real work even more impossible. In spite of the cold douche of authority, we are told; in spite of the attitude of labour-leaders, once bit twice shy; and in spite of the enthusiasm ever seeking a new rallying ground for lost causes, workers, when they are left to themselves to plan their own scheme of salvation, choose for their education vocational and technical work. The average man glories in his daily work and trade so long as his heart is kept in it by his being treated as a human being rather than as a machine. In the spirit of craftsmanship, better than in medieval and drawing-room studies, is to be found the remedy for the evils of industrialism.

Science, the gift of the age, notwithstanding its repercussion upon the foundations of society, has not yet penetrated appreciably into our institutions of governance and education. It is the bed-rock upon which all future educational ideals must be based, and the new creative spirit it has reincarnated in the world—its spirit of inquiry for the love of truth for its own sake and its spirit of co-operation with others engaged in the same work—is that by which the age must outgrow the nightmare which the old spirit has made of it and the world. Scientific thought and research must be applied to creating new wine-skins rather than more new wine until this is put right. It has demolished the cobwebs of traditional economics and finance and substituted for them fundamental conceptions of the laws by which men live and move and have their being. It meets no opposition, and scarcely even discussion, now from the professional exponents of the merits of the existing *régime*. Were it not for private interests and the ignorance of its ruling classes science would not have any difficulty in restarting the world on saner lines.

What is especially remarkable about this is that it is no vision of a dreamer, "sicklied o'er with the pale cast of thought," but rather that of a practical public-school headmaster, who has burst open the prison-doors of the pedagogic strongholds of the past and reclaimed for the schools the right and duty of serving and studying their own age. If there were ten such men, haply they might yet be in time.

This picture from a schoolmaster of what could be done in the school opens out broader visions of what universities might accomplish. They are in the most extraordinary case. They can claim that they have given in the research ideal of science—the finding out of the fundamentally new, *not* the mere rediscovery of the old that has been lost—the creative agency by which alone the modern world is great or even distinguished. But it has been done in the teeth of official apathy and discouragement. On the other side of the balance sheet is the traditional education they continue to give to the ruling classes, training them to be impervious to new knowledge and able only to find in the old and dead past ideals for imitation and reverence. These ideals and maxims have set the producers of wealth of the modern world at one another's throats for the benefit of its wasters. The code of laws remains as in olden time, though its obvious result has been to turn to debt the increase in the wealth of the community which the labours of scientific investigators have made possible. The world despises such results and wants something more from its old universities than that they should be beggars for their existence for crumbs from the tables that its own schools of science have loaded with gifts. It looks to them for a clear enunciation of the first right of the community to the produce of its own labours, which the law allows by taxation, for the upbringing of its own youth and for the cultivation of its creative institutions where knowledge is made and disseminated. The claim of the usurer upon that produce is secondary both by law and by common sense. And, lest again the stability of the world be endangered by its rulers being educated on myth and verbal subtleties to the total exclusion of the laws that appertain equally to Nature and to life, let them in the spirit of Plato inscribe over their reformed portals:—

"Let no one enter who is destitute of science."

FREDERICK SODDY.

British Aeronautics.[1]

THE Report of the Advisory Committee for Aeronautics for the year 1918–19 is an interesting record of work achieved, which acquires additional interest by including a general review of progress made since the beginning of the war. More than ever, after reading it, one is impressed by the range and extent of the demands which this new industry has made upon existing knowledge; of the structural engineer it requires that its stress calculations and the testing of its materials shall be conducted with an accuracy never contemplated before; of the mechanical engineer, that its engines shall be economical both of material and of fuel to a degree which until very recently would have seemed almost

[1] "Aeronautics." Report of the Advisory Committee for Aeronautics for the Year 1918–19. Pp. 77. (London: H.M. Stationery Office, 1920.) Cmd. 488. Price 4*d*. net.

fantastic; and, above all, of its pilots, that with the skill and technique peculiar to their craft they shall combine a practical working knowledge of structure and of machinery, of instruments and "wireless," of meteorology and of navigation, which in other professions would be the province of different specialists. And this universality, as might be expected, is no less characteristic of the appeal which aeronautics has made to the man of science, who provides it with fresh data; so that it is not surprising to find that the single committee of pre-war days has been compelled to adopt a policy of devolution, and that special sub-committees have been formed to deal with problems of such different scope as "scale effect," the investigation of accidents, internal-combustion engines, light alloys, meteorology, atmospheric electricity, and new inventions.

The report abounds with indications of fields in which further research is needed, and there seems every reason to believe that this research will be prosecuted with equal success under the auspices of the newly constituted Aeronautical Research Committee. We learn with satisfaction that the demand for the earlier technical reports has been vigorous enough to justify the printing of a complete second edition, since an opportunity is thus given for inserting much more complete cross-references than were possible when they first appeared. It is, perhaps, a matter for some little regret that a more definite lead has not been given in this direction by the present report. We imagine that any reader whose interest in the subject extends to the detailed reports of the several sub-committees would wish to have such references to individual papers and their authors as will enable him to find additional information on any special point; moreover, an account so detailed, and yet empty of names and references, may fail to impress what we believe is the secret of British supremacy in aeronautics: that our official Committee has interpreted its functions as being advisory rather than executive, and has endeavoured to assist, co-ordinate, and encourage research rather than to originate and control it.

No useful end would be served, and perspective would be lost, by abstracting from these excellent and thoroughly condensed reports. Their range is very wide, extending from complete investigations, on both the practical and theoretical sides, of such complex evolutions as "spinning" to researches on the properties of light alloys, the transmission of heat from rough and smooth surfaces to passing currents of air, the conditions leading to discharge of atmospheric electricity from kite-balloons and cables, and the best shape for parachutes. Few, we believe, will read these pages without discovering some points of contact between aeronautical science and their own particular field of investigation.

Mention should be made of the very interesting table of comparative performances of British aircraft which is included as an appendix.

Climatic Cycles and Tree-growth.

PUBLICATION No. 289 of the Carnegie Institution of Washington is devoted to Prof. Douglass's study of the annual rings of trees in relation to climate and solar activity. When the late Prof. Lowell was seeking an ideal climate for his observatory, with the view of studying the planet Mars, he chose the dry region of Flagstaff, Arizona, on account of its low rainfall and high proportion of clear skies. While Prof. Douglass was at the Lowell Observatory it occurred to him that variations in solar activity might have a measurable effect on tree-growth, since the latter was probably dependent on rainfall, and rainfall might very likely be affected by solar activity. He began by studying the yellow pines of those arid regions, arguing that a very dry climate should be the best for such an investigation. He soon found that the intimacy of the connection between the width of the annual tree-rings and the rainfall, when the latter was known, was far closer than he had dared to hope, and he pushed further afield, examining tree specimens and fossils in European collections as well as in other districts of America.

Considerable labour was involved in the interpretation of the various appearances of the rings, the red tissue that denotes the close of a period of growth. The year starts in the autumn. With normal winter snow and spring and summer rainfall growth continues throughout until the autumn, and a ring of normal width is produced. If winter snow is deficient and spring rain also scanty, a narrow ring is produced, closing prematurely without waiting for summer rain. An intermediate condition is shown when winter snow is deficient and the spring drought is not so severe; red tissue begins to form, but growth starts again, and the result is a double ring for the year.

The author considers that five trees in a group give a trustworthy result in general, though in a very dry district like Arizona two might suffice. The only district where five trees failed to give a satisfactory cross-identification was a rugged region near Christiania, in Norway.

The Flagstaff record is complete from A.D. 1385, but among the sequoias of California stumps are in existence dating back more than three thousand years. Some of these sequoias grew on hillside slopes, and others in basins where plenty of moisture is found at all times. The latter are unsuitable for investigation, and the author calls them "complacent," as they show practically no variation in the annual growth. The others he calls "sensitive," as they have to depend upon snow melting down the slope and upon rain as it comes, not being provided with any storage such as that found in the basins. Some specimens, including the oldest of all, showed signs of a change in environment, "complacent" in later growth but "sensitive" earlier. Prof. Huntington had previously investigated these sequoias in his search for evidence of climatic change, but his purpose was served with much less detailed measurements, ten-year periods being short enough for his unit of time. His dates agree fairly well with those of the present work. The analysis of the data for periodicities required considerable accuracy in the method employed, and ultimately led to the adoption of the "automatic optical periodograph," of the construction and application of which full details are given.

Practically all the groups of trees investigated show the sun-spot cycle or its multiples; the solar cycle becomes more certain and accurate as the area of homogeneous region increases or the time of a tree record extends farther back; this suggests the possibility of determining the climatic and vegetational reaction to the solar cycle in different parts of the world. A most suggestive correlation exists in the dates of maxima and minima found in tree-growth, rainfall, temperature, and solar phenomena, pointing to a physical connection between solar activity and terrestrial weather. There is a very important point discussed under the title of "Meteorological Districts." It is essential to restrict any such district for this purpose to one in which homogeneous weather conditions are found. Clearly, if one set of conditions makes one district wet and a neighbouring district

dry, these cannot be lumped together for correlation purposes, as the whole effect will be masked. We are reminded of the sun-spot maximum of 1893, which was associated with great heat in England and France, but was exceptionally cold in America and other parts of the world. This limitation of districts may not, as the author recognises, be the same for short periods as for long ones, but he finds the major characteristics in mountain regions very much alike over distances of fifty or sixty miles, and relies upon the evidence of the trees themselves for the demarcation of the districts.

One other small difficulty Prof. Douglass has met in an ingenious manner. It is often noticed that such an element as rainfall, when expressed as departure from the mean, as it must be in correlation problems, is arithmetically lacking in symmetry, since the defect can only be 100 per cent. at most, while excess can be very much larger. Geometrically, this can be avoided by using a logarithmic scale, but this flattens the variation very much. Prof. Douglass's device is to leave the deficient amounts unaltered, but in the case of excessive falls to invert the fraction and measure upwards from the normal. Thus a rainfall of twice the normal is indicated by a point just so far above the normal line as the point indicating a rainfall of half the normal is below it. The symmetry is not perfect, as, of course, no possible wetness can give a point corresponding to zero rainfall, but the method is convenient in places where zero rainfall in the unit period is unknown. W. W. B.

The Interferometer in Physical Measurements.[1]

A FOURTH volume describing the researches of Prof. Carl Barus with interferometers has recently been issued. The classical work of Fizeau, who applied interference methods to the determination of expansion coefficients, directed attention many years ago to the possibility of the kind of work which has been so well developed by Michelson and others, and in the present series of papers Prof. Barus seeks to develop the methods of application of the interferometer to a somewhat wide range of physical measurements. These include spherometer measurements, elastic deformation of small bodies, elongations due to magnetisation, pressure variation of specific heat of liquids, and even electrodynamometry. The remainder of the volume deals with various modifications of the interferometer methods and with certain gravitational experiments.

Doubtless such an investigation of methods will be useful to workers in any of the foregoing fields, but so far as a first impression is to be trusted it would appear that the main interest has lain in the *method* rather than in any results which have been attained.

In order to study the motion of a contact lever, it may be made to carry two small mirrors reflecting normally two beams which are afterwards caused to interfere. Any rotation of the lever obviously causes a difference of path, which appears in the shifting of the easily recognisable and distinctive central "achromatic" interferometer fringes, such motion being measured by a plate micrometer or "graticule" in the observing telescope.

The two mirrors form the limbs of a "T" piece, which is pivoted about a hinge at the end of the foot. One limb ends in a contact pin which abuts against the surface, the motion of which is to be measured.

In such circumstances Prof. Barus estimates the limiting sensitiveness to be 33×10^{-8} cm., or perhaps even a third of this amount; but it should not be forgotten that the very simple interferometer system of an optical test-plate has a sensitiveness of about a quarter wave-length, say 12×10^{-6} cm., and this without a doubtful hinge and another contact. The contact lever can, of course, deal with non-specular surfaces, but to use it as a spherometer for a glass lens seems quite needless. Naturally, an apparatus of this nature is excellently adapted to such a problem as that of investigating the changes of length of a magnetised rod, and, although no very novel results are obtained, the investigation has been comparatively easy, and the method is well adapted for demonstration.

Suitable self-adjusting interferometers, such as are described in chap. vii., ought to find an increasingly useful place in the physical laboratory, and students should be taught the practical use of such instruments and their modifications. There is too great a tendency to treat an interferometer as a piece of apparatus sacred to one or two highly specialised purposes, but with little more than a few pieces of good plane parallel glass a set of instruments can be made up which should be of the greatest use in teaching and research.

One could wish, perhaps, that some one problem had been attacked and solved thoroughly. The curiously unfinished nature of the work is disappointing, but we must conclude that the method is the chief object. As regards the text, the descriptions are clear and praiseworthy, but the diagrams are both inadequate and unsatisfactory. L. C. M.

[1] "Displacement Interferometry by the Aid of the Achromatic Fringes." Part iv. By Prof. Carl Barus. (Carnegie Institution of Washington, 1919.)

Canvas-destroying Fungi.

WHEN men again began to take to their tents at the outbreak of war, many noticed that dark brown and black spots, frequently of a diamond shape, were not uncommon on the canvas. Small, surreptitiously acquired bits began to be scattered around for information as to the identity of the moulds causing the rot. Now it is very surprising that so little work has been done on canvas-destroying fungi. That canvas is liable to suffer from moulding seems generally to be known, judging from the fact that any material likely to get wetted is usually "cutched." Shortly before the war aircraft workers began to interest themselves in the fungi concerned in the damage, but it was not until war broke out that one realised the extent of the destruction of sails, tents, etc., by these organisms.

Major W. Broughton-Alcock, in the Journal of the Royal Army Medical Corps for December last, gives a short account of investigations carried out by him in Malta, Italy, and (in conjunction with Miss A. Lorrain Smith) at the Natural History Museum. In Malta attention was soon attracted to the rapid spotting and destruction of tentage—awnings last there only about a year. The investigators found that the principal agents of destruction of cotton- and flax-made canvas are Macrosporium and Stemphylium. The latter is the more prevalent in Malta, and could be isolated by exposing culture plates to the air. The colours of the spots on canvas correspond to the colours seen in cultures, being first brown and then black. The variation in the colour of the spots, especially noticed in flax-made and more resistant canvas, was found to be due to other fungi in association with the above genera—Septoria, Alternaria, Helminthosporium, Chætomium, Exosporium, Penicillium, Oospora, Torula, Saccharomyces, and yellow pigment-forming and other air-borne bacteria. Though

these fungi may assist in the destruction, no proof was obtained that this took place without the presence of Macrosporium and Stemphylium. The fungi grew well on Sabouraud's medium and on ordinary agar.

According to the author, the first signs of fungoid growth appear on the inner side of the roof portions of tents and marquees. Often within three months pressure on the spots made by the fungi leads to perforation, or a strong wind causes tearing.

Cotton and linen duck-canvases ready for tent-making were examined, but, though the flax fibres were in good condition, brown mycelium was found more or less in abundance. It is suggested that the fungi reach and begin growth during the retting of the flax, though they may be present on the growing plant. Mycelium was not found on new cotton-made canvas, and "this is not surprising when its method of preparation is studied." It is not, however, probable that the infection of linen canvas is restricted to the period of retting. Guéguen (NATURE, vol. xcix., 1917, p. 206) was of the opinion that fungi from the dead stems of the textile plant were introduced amongst the fibres. This might account for their absence from new cotton-made canvas, but there is little doubt that both linen and cotton canvas often become infected after having been made up.

Experiments showed that the Willesden (cuprammonium) method and cutch treatment prevented the growth of the fungi. A method suggested by Prof. Pinoy (soft soap 1 in 5000 solution, followed by a mixture of 1 per cent. of alum and $CuSO_4$) greatly inhibited the growth, and its extended employment in Malta gave very satisfactory results. Mango-treated canvas was in no way inhibitive.

No mention is made as to whether the "cutch" was the ordinary commercial cutch (product of Acacia, etc.) or whether it was sodium chromate, which was used in certain areas. In Salonika this was found the best preventive for "diamond spot" on comparison with Guéguen's and Pinoy's treatments, and was at the same time a satisfactory camouflage.

J. RAMSBOTTOM.

The Economic Pursuits of the Trobriand Islanders.

AT a meeting of the Royal Anthropological Institute held on Tuesday, June 1, Mr. S. H. Ray, vice-president, in the chair, Dr. B. Malinowski read a paper on "The Economic Pursuits of the Trobriand Islanders." In his opening remarks Dr. Malinowski criticised the methods usually followed by observers in dealing with the economics of primitive peoples. Whereas it was usually held that such peoples were preoccupied solely with obtaining an adequate individual food supply, he had found that, at any rate among the peoples which had come under his observation, there was a highly complex economic organisation. In support of his view he described the economic system of the natives of Kiriwina or the Trobriand Islands, lying to the north of easternmost New Guinea. These natives are very efficient and industrious tillers of the soil. Agricultural production is highly organised, being based upon two social forces: the power of the chief and the influence of magic. The chief is overlord of the garden-land, and initiates in each season the allotment of garden-plots to individuals and settles any disputes about garden-land; he finances any communal work to which the natives resort when clearing the bush, planting the yams, and bringing to the gardens the big, heavy poles used in connection with magical rites. On the other hand, the traditional garden magician controls the detailed proceedings of the work and performs magical rites at each stage.

There are several customary forms of communal work. An interesting institution of ceremonial enterprise, called *Kayasa*, is applied to gardening, fishing, oversea expeditions, and industrial activities, as well as to tribal sports, games, and dancing. Such a period of communal work is announced by the chief, who gives a big feast, which is followed during the continuation of the work by periodical distributions of food. Fishing, the building of houses and canoes, and other economic activities are based upon organisations similar to that of gardening. All are dependent upon the social power of the chief and the influence of the respective magician.

The distribution of the products is as highly organised as the production. The producer receives a certain portion, but a considerable part is used for the financing of big tribal enterprises through the chief, and another part is transformed into permanent wealth. By various tributes, dues, and offerings the chief collects about 30–50 per cent. of the tribal wealth, and he is the only member of the community who is allowed on a large scale to transform it into permanent wealth. This he does by keeping a number of industrial workers dependent on himself, who, for payment in food, produce polished "ceremonial" axe-blades, neck-strings of red shell discs, and arm-shells made of the conus shell, which are of very high value in the eyes of the natives, form the foundation of certain kinds of native trade, and are an indispensable feature of the social organisation of the natives. Every important transaction, whether ceremony or magical rite, birth, death, or marriage, has to be accompanied by gift and counter-gift. These are arranged, as a rule, so that while one party gives a substantial present of food, the other offers one of the tokens of native wealth, such as a ceremonial axe-blade, an arm-shell, or a string of shell discs. The powers of the chief are largely exercised through economic means. In inter-tribal affairs the chief backs up with gifts his summons to arms of his vassals, and the conclusion of peace after hostilities; and the same method of remuneration was followed when, in his narrower jurisdiction, direct punishment was meted out by ordering a special henchman to kill the offender or by calling upon a sorcerer to cast an evil spell on the victim. In both cases payment for the service was made in native tokens of wealth. These tokens of wealth have sometimes been designated by the term "money," but rather they represent stored-up wealth. Although a basketful of yams, a set of four coconuts, or a bundle of taro is, to a great extent, the common measure of value, there is no article among these peoples which, properly speaking, fulfils the function of a medium of exchange.

Two of these tokens of wealth, the arm-shells and the necklaces of shell beads, are used for a remarkable form of trade, called by the natives *Kula*, which embraces a ring of islands and archipelagoes lying to the east and north-east of British New Guinea, in which these two articles circulate in opposite directions. They are constantly being exchanged, scarcely ever being put to any use, but returning after a few years to the same district whence they were originally sent out, and then being traded again. The exchange is of a highly formal and ceremonial character, based on mythological tradition, and carried on according to very complex and rigid rules. Extensive and daring oversea expeditions in big sea-going canoes are made year after year, mainly in order to carry on this exchange. It involves a singular form of ownership, by which a token of wealth never remains in the hands of one man for any length of time. Instead of owning one article permanently, he owns a great number of articles temporarily. As a result of this

investigation it would appear that chieftainship, kinship, and social organisation in general are intimately bound up with the economic organisation.

In the discussion which followed the reading of the paper all the speakers emphasised the value and originality of the view of primitive culture which Dr. Malinowski had formulated in his interesting communication. Prof. Seligman asked how far the elaborate organisation of garden cultivation depended upon the existence of the chieftainship. Among the Southern Massim of New Guinea, for instance, there were no chiefs, and the native social organisation was based upon the hamlet. Had the elaborate garden organisation been observed among such peoples?

Sir James Frazer agreed that the economic aspect of primitive culture had not been adequately studied. It was interesting to note how the tribal economics were saturated with magic, and how the fallacy of magic still persisted among people who had developed a high system of agriculture. The mention of torches used by the magician in the ceremonies led him to compare the torches to which reference was made in the Greek legends of Demeter's search for Persephone. Was it possible that these torches represented a survival of a use of torches in early Greek agricultural ceremonies similar to that to which they were put in the Trobriands?

Mrs. Routledge suggested that an analogous complexity of economic organisation might be found among the people of East Africa with whom Mr. Routledge and herself had come into contact, where ivory played an important part.

Mr. Ray said that Dr. Malinowski had submitted a new view of ethnological investigation to the institute. Some of the ceremonies described by him suggested ceremonies from the other end of Melanesia, namely, Loyalty Island and New Caledonia, where the agricultural operations were directed by the chief, who prescribed what ground should be put under cultivation, the kind of crop, and the like, and received the first and best of the produce. Was it possible that these complex economic systems existed wherever there were chiefs whose position, power, and prerogatives depended upon the fact that they were of extraneous origin?

The lecturer in his reply stated that although garden magic was carried out by the Southern Massim at Dobu, cultivation was not accompanied by such a complex organisation for distribution.

The Organisation of Scientific Work in India.

THE Indian Industrial Commission during its tour through India found that all was not well with the scientific worker, especially in connection with the application of his work to industrial development. While stating specifically in its report that "we do not propose to deal with the general problems of pure scientific research," it adds: "We were impressed by the value of the work which had already been done in the organised laboratories, and by the absolutely unanimous opinion which was expressed by all scientific officers as to the inadequacy of the staffs in point of numbers. Everywhere we were brought face to face with unsolved problems, requiring scientific investigation on an extended scale. On the one side, we saw the results accomplished by enthusiastic scientists, which, regarded from the purely economic aspect of the question, have added enormously to the productive capacity of India; on the other side, we were told by forest officers, agriculturists and indigo planters, engineers, and manufacturers, of the limitations placed upon the development of their work and the frequency with which they were brought to a standstill by a lack of knowledge regarding matters which could only be ascertained by systematic research work." It is clear from these and other passages that the Industrial Commission desired to direct attention to the necessity for the elaboration of some scheme by which an organised attack might be made on the large number of problems awaiting solution in connection with the development of industry, and the conclusion reached is that "the maintenance of a staff of suitable technologists and scientific experts is essential to industrial development."

The Commission then gives its reasons for considering that it is the duty of the State to provide the necessary facilities, and concludes: "We have thus no hesitation in recommending a very substantial increase in the scientific and technical services as essential to industrial development." A general discussion follows as to the relative merits of a system in which the science is the bond, and one in which the bond is formed by the application of the sciences dealt with. In the first case the Geological Survey is given as an example, and the Agricultural and Forest Departments are quoted as examples of the second. But it is clear that the Commission was fully alive to the difference between a service and a department, and realised that the differentiation given above was the same as that between a service and a department, because it says: "The constitution of a certain number of scientific services based on the assumption that the science itself is a chief link between all members does not prevent the formation of departments, either Imperial or provincial, where the application of various sciences is the chief bond of union." The essential difference between the two types of organisation is clearly indicated in subjoined extracts from a despatch of the Government of India.

The Commission states that its proposals in the case of chemistry will have to be submitted to a special committee, and that it "hesitates to offer suggestions in greater detail regarding the organisation of the Imperial scientific services for bacteriology, botany, and zoology, as we consider that the best plan will be the appointment of special small committees for the purpose of formulating proposals." The first of these, that for chemistry, has now reported, and the report is open for discussion. As regards other sciences, it would be best to await the reports of the other committees before offering any remarks upon them.

The following extracts from the Government of India's dispatch dated June 4, 1910, place in a very clear light the intentions which underlie the recommendations of the Commission:—

The Scientific Services.

One of the main proposals refers to the constitution of scientific services and of an industrial service. The Commission direct attention to the extreme importance of research under modern industrial conditions, and to the especial needs of India, in view of her vast unexploited resources in raw material and of the paucity of her scientific workers. They criticise the complete lack of organisation among men of science employed by the Government, and describe the difficulties, both administrative and technical, to which this gives rise. The Commission recommend as a remedy the creation of a similar mechanism to that through which the Central and Local Governments have hitherto carried out almost all their most important activities, especially those requiring technical knowledge, viz. all-India services; and they discuss the basis on which these services should be con-

stituted. The Commission propose the creation, not of scientific departments, but of scientific services—an essential distinction which has been clearly brought out in the replies of Local Governments, though it has not been so clearly apprehended by critics of the proposal. The Commission contemplate the recruitment of officers into separate scientific services, such as a Chemical, Botanical, or Zoological Service, for employment under Imperial and provincial departments, such as Forests and Agriculture, which deal with the application of a number of separate sciences. They propose that scientific officers in the employ of the Government, instead of being recruited in small numbers or single units into the different services which happen to require them, should be recruited as experts in their several sciences into scientific services, each with its appropriate conditions of qualification, pay, pension, and promotion. Although the services will be distinct entities for the above purposes, yet the only members of those services that will not be actually employed under the various departments that require their services will consist of a central staff, engaged under such officers, for instance, as Deputy Chief Chemists, at research centres, in scientific work. This central agency will also serve as a reservoir to meet the demands that may be put forward by other departments or by Local Governments for men to undertake temporary special investigations, to fill new posts or leave vacancies, or for the replacement of existing officers.

The head of each scientific service would thus exercise an influence over the members of his service in matters scientific, by the check of scientific results, and by the provision of advice and criticism on scientific work, whether for Local Governments or for research workers. It is not, we understand, proposed by the Commission, nor do we ourselves contemplate, that he should actually control research work in the sense of ordering definite problems to be taken up by officers serving under Local Governments, or should turn his department into a gang of hack researchers. We rely on constant correspondence between scientific officers of the same caste and periodical conferences as sufficient to correlate research programmes.

Local Governments and heads of Departments find the greatest difficulty in forming an opinion of the work done by men of science employed under them, or of the probable value of lines of research proposed by their officers. Should the administrative authority consider the results obtained by a man of science unsatisfactory, it is almost impossible to obtain an authoritative opinion on his work or qualifications; or to say whether he might not do better in another post; or to find such a post for him. The difficulties arising from the existence of isolated specialists in a department are, in fact, notorious.

The impossibility of applying any common measure in determining the respective claims to promotion of a botanist, a chemist, an engineer, and a political economist has been recognised in the existing services by the creation of separate posts on a time-scale. But this does not get over the difficulties already indicated, or supply the proper incentive to the research worker, or afford scope or prospects for men of more than average ability. The absence of such prospects is bound to militate against our chances of obtaining good recruits, to render our staff discontented, and to prevent our securing the best work from the best men.

Moreover, so long as students of a particular science are recruited sporadically on behalf of different departments as vacancies occur, the Government will have to accept the men that happen to be left over, whatever their qualifications, after other and more regular demands have been supplied. The prospect of regular annual recruitment will enable the Government of India to fill its future demands for men of science, as it has hitherto done for engineers, forest officers, and medical men.

The present system, under which the only chemists employed by the State are scattered through numerous departments without any organisation that can marshal the chemical forces of the country to attack problems of national importance, can give no help towards an active industrial policy.

We might quote as illustrating the inspiring value of a central co-ordinating authority, the work undertaken by the Munitions Board through its chemical adviser. The report of the conference of chemists at Lahore shows that even our isolated and scattered chemists can be moulded into one team for the purpose of suggesting new lines of research and means for turning the results to practical account without overlapping and consequent waste of effort.

This experience, in the light of the magnificent results obtained in England by the Research Committee of the Privy Council, shows clearly how much may be expected from a system which provides a permanent organic connection between all chemists in Government employ.

The importance of a common system of recruitment and of a common service has recently been recognised by the council of the Institute of Chemistry in the United Kingdom (*vide* Proceedings of the Institute of Chemistry, 1918, part iv., p. 14) in a representation submitted by them to all Government Departments in which chemists are employed. They state their opinion that "the time is opportune for taking steps to secure for the provision of chemistry a position corresponding to that occupied by the learned professions, and they feel that much would be accomplished towards the attainment of that end if, in the first place, adequate and uniform conditions of appointment were accorded to chemists directly engaged in the service of the State. The necessity for a definitely organised chemical service (both in peace and war) for all purposes of the State on which the science of chemistry has a bearing has long been recognised in the chemical profession."

Conditions in India render the services of chemists employed under Government of even greater relative importance than in England. India is far more deficient than England in the knowledge of its raw materials and of the appropriate industrial processes; consulting chemists and chemists in private employ are almost entirely absent here, and this deficiency is not likely soon to be remedied. Research institutes with special reference to a particular industry in England, it would seem, will usually be financed and controlled by the industry itself, with a Government grant-in-aid, whereas in India the position will be precisely the opposite, and the industry will rely primarily on State chemists. We therefore agree with the Commission that the advancement of industries in India must depend for scientific assistance almost entirely on State-employed men, and these men will be far more concerned with the initiation of important new lines of development and research and far less with merely routine work than is the case in England. The need of organisation is the greater in that the functions of Indian State chemists are more important to the country; while their greater isolation and the consequent absence of a scientific atmosphere furnish an additional argument. The case for a State chemical service is thus even stronger in India than in England.

We are much influenced by the prospects which the proposed system affords of increasing the number of

Indians in the scientific services. An Indian appointed to an isolated post, or as an assistant to an isolated professor in a country where the scientific atmosphere is non-existent, or at the best exceedingly attenuated, lacks guidance and the stimulus of his fellows in the pursuit of scientific knowledge. His ambitions tend to become limited to the improvement of his pay and prospects rather than of his professional attainments. His membership of an all-India service, based on the pursuit of a common science, will increase the prestige of that science in his eyes and in those of the Indian public; the existence of the proposed Imperial nucleus of scientific workers under a distinguished chief will provide him with an incitement to excel with assistance in his studies and with opportunity for training if he desires it.

The Commission propose that, if the principle of scientific services is approved, committees should be appointed to formulate proposals for the permanent organisation and the terms of employment of each such service, and for the location and equipment of research laboratories. We support this recommendation, subject to the condition that the terms of reference to each committee should include a direction to report as to the advisability of constituting all-India services for each well-defined science.

Without anticipating the conclusions of the proposed committees, we think it desirable, in view of criticisms which have been expressed, to indicate certain principles in the general administration of these services which should govern the relations between the members of the scientific services and the heads of departments and provincial Governments, under whom many of them will be employed.

We do not think that members of scientific services should be seconded by the method which the Commission propose, viz. by deputation for periods of five years at a time; but we consider that (as in the case of other services) an officer, when once placed permanently under the orders of a local Government, should remain with the Government for the rest of his service, unless the Government under which he is serving itself desires his transfer, or unless his services are required in a higher post or in a post requiring special qualifications outside the province, in which case the local Government will recognise that the Imperial Government has a claim on them. This is the system which exists at present in respect of all similar services.

Local Governments would have complete liberty to appoint, after consulting the head of the service, to any post in their industrial or scientific cadre, any available member of the respective services; they would also be at liberty, in the special circumstances arising during the initial stages, to appoint to such posts men outside the service; but the subsequent admission to the all-India service of men so appointed would be entirely controlled by the Secretary of State. The local Governments universally support the proposed scheme of scientific services, and though the Governments of the Punjab, the United Provinces, and Bombay, and the officers and public bodies consulted by them, put forward certain criticisms of the scheme, especially with reference to the position of men of science in the Education Department, these criticisms are, we think, fully met by the foregoing explanation of the lines on which we think the proposed services should be administered.

We desire, however, to add a few remarks with special reference to the case of science teachers. We fully recognise that much is required of a scientific professor in a college, outside his scientific work. He must look on himself as a member of the body responsible for the tone of the college and for its general success. It will, therefore, we agree, be most undesirable that such a man should continuously have in mind the possibility of promotion outside his own department. We think, however, that this difficulty will be obviated by the general principle laid down by us above, viz. that members of scientific services serving under the Department of Education should not be removed from that Department, unless at the request of the educational authorities, or for posts requiring high administrative capacity, or special scientific qualifications.

The advantage to the Education Department of a system of scientific services will still be very considerable. In the first place, we consider that, though university and college science workers should be by no means entirely divorced from technical research, their main sphere of activity should lie among problems of pure science. The proposed central scientific organisation should afford a means whereby such problems arising in the course of technical research can be referred to university and college laboratories.

Such co-ordination, both in respect of pure science problems and technical problems, can be most readily effected in cases where the educational researchers are themselves members of a scientific service. This policy will doubtless stimulate the interest in research work taken by students and professors. Officers who have entered the educational service as teachers may be in some cases expected to develop as research workers. The existence of all-India scientific services will afford a ready means for accommodating men whose aims in life have thus been diverted from one form of work to another. In the next place, the present system of recruitment of men of science into the Educational Service is capable of improvement, and far better results could be obtained with the aid and advice of watchful central agencies in India. The absence of a scientific atmosphere, again, has been particularly injurious to scientific officers in the Educational Service, and has led to great stagnation in respect of research work. This atmosphere will in future reach individual officers by the numerous channels of communication which will be created between them and the central agency on technical subjects, whether by way of correspondence, conferences, and scientific publications, by the central staff's tours of inspection, or by officers spending some portion of their vacations at research institutes. The case of men of science at present employed under the Department of Education will obviously require careful treatment; such men should not be allowed to join the scientific services as a matter of course, but each case will have to be considered on its merits, and there may still be classes of appointments for which men will have to be recruited independently. Further, the whole question, so far as it affects the employment of officers with scientific qualifications in colleges and universities, will have to be reviewed in connection with the proposals of the Calcutta University Commission regarding recruitment.

In addition to the opinions expressed in the letters received from local Governments, two important conferences of chemists have recently put forward their views on the Commission's proposals. A record of their discussions is appended. A full meeting of the Sectional Conference of Agricultural Chemists at Pusa in February passed the following resolution:—

"That this Conference considers that, in view of the intense local knowledge required for effective work for agricultural improvement by chemical methods, it is not desirable that the chemists in the Agricultural Departments should be formed into a service apart from the ordinary agricultural service,

in which the bond of union would be the science rather than its application. On the other hand, in addition to agricultural chemists attached to the Provincial Departments, this Conference is definitely of opinion that a strong central body of chemists should be maintained by the Imperial Department of Agriculture from whom Provincial Departments could draw for the investigation of special problems."

The main objection taken was, it will be observed, based on the idea that men would usually be transferred after five-year periods. We have explained already that such idea forms no part of the system which we contemplate. It is also significant that the same resolution declared the necessity of a strong central body of chemists for the Department of Agriculture; and, it may be added, the same meeting pointed out the desirability of equipping the agricultural research organisation to deal with certain industrial problems arising out of agricultural research. The sum of these conclusions seems to point to the desirability of supplying some agency which can correlate chemical research with agricultural and industrial problems, and of avoiding the needless expense of creating separate research nuclei for dealing with each separate class of chemical problems.

A conference of chemists was convened in Lahore in January, 1918, by the Indian Munitions Board. It included not only Government officers, but also chemists attached to missionary colleges and employed under private firms. The conference passed no formal resolution, but strongly supported the proposed system of scientific services.

University and Educational Intelligence.

CAMBRIDGE.—As stated in our issue of June 24 (p. 537), a donation of 1000*l.* has been received for the provision of lectures on tropical agriculture for five years. Dr. C. A. Barber has been appointed as lecturer in tropical agriculture.

Dr. F. W. Aston has been elected to a fellowship in Trinity College.

In presenting Sir Joseph Thomson and Sir Joseph Larmor for honorary degrees at Cambridge recently, the Public Orator spoke as follows: "Democritus, philosophus ille antiquus, ut mundum explicaret, atomos finxit, solida rerum primordia, non partium conventu conciliata,

'sed magis æterna pollentia simplicitate.'

Sed, ut discipulus illius ait, difficile est credere in rebus esse quidquam solido corpore, quod demonstravit Professor noster. Atomum enim ipsum ingressus, partes discrevit, ordinavit, legibus subjecit. Immo ut Græcus ex atomo κόσμον eduxit, Anglus in atomum κόσμον introduxit. Et multa quidem ejusmodi investigavit, quæ dicere non concedit Latini sermonis egestas; hoc saltem concedit exponere, quanta universorum lætitia collegio suo Magistrum a Rege impositum nuper viderimus." And: "Adest alter e burgensibus nostris, idem rei physicæ Professor, Isaaci Newton et Georgii Gabrielis Stokes non indignus successor, Societatis Regiæ olim a secretis, qui scientias innumeras provinciam sibi depoposcit et illustravit. Ut carmen quoddam cenaticum discipulorum commemoremus

'æthera materiemque electraque cogitat ille
somnia quæ possint mentes confringere nostras.'

Sed quem mundus ut virum sollertem ingeniosum sapientem miratur, illum collegium suum amicum diligit, providum modestum fidelem. Quem si amplissimis honoribus hodie extollit Academia nostra, hoc multæ et apud nos et apud exteros facere occupaverunt.'"

EDINBURGH.—Her Majesty the Queen has consented to accept the honorary degree of LL.D. on the occasion of the impending laying of the foundation-stone of the new chemistry department.

GLASGOW.—The degree of D.Sc. was conferred on June 23 on the following:—P. A. Hillhouse, for his thesis "Ship Stability and Trim," with other papers, and D. B. Meek, for his thesis "Cyclonic Storms in the Bay of Bengal for a period of thirty years, from 1886 to 1915 inclusive, with special reference to their Location and Direction of Motion," with other papers.

On the same occasion the following special class prizes were awarded:—Mathematics (Advanced Honours Class): The Cunninghame gold medal to J. M'Kinnell. Natural Philosophy (Ordinary Class): The Cleland gold medal to D. H. Findlay. Political Economy: The Alexander Smart memorial prize to Stewart Mechie. Moral Philosophy (Honours Class): The Edward Caird medal to I. W. Phillips.

On June 24 the degree of LL.D. was conferred on Dr. J. MacIntyre and Sir Robert W. Philip.

LONDON.—At a meeting of the Senate on June 23 Dr. S. Russell Wells was re-elected Vice-Chancellor for the year 1920–21.

Communications were received from the University College Committee and from the Dean of the University College Hospital Medical School, setting forth respectively the terms of the recently published offers made by the Rockefeller Foundation to present (*a*) to the University, on behalf of University College, the sum of 370,000*l.*, and (*b*) to University College Hospital Medical School the sum of 835,000*l.*, for the advancement of medical education and research. Resolutions were adopted expressing the Senate's grateful appreciation of the magnificent generosity shown by the Trustees of the Foundation to the University and to the Medical School of University College Hospital, and accepting the offer made for the benefit of University College.

Mr. A. E. Jolliffe, tutor in mathematics at Corpus Christi College, Oxford, was appointed to the University chair of mathematics tenable at the Royal Holloway College; Dr. B. J. Collingwood (professor of physiology at University College, Dublin) to the University chair of physiology tenable at St. Mary's Hospital Medical School; Prof. L. R. Dicksee to the Sir Ernest Cassel chair of accountancy and business methods tenable at the London School of Economics and Political Science; Mr. H. C. Gutteridge to the Sir Ernest Cassel chair of commercial and industrial law tenable at the London School of Economics and Political Science; Mr. T. E. G. Gregory to the Sir Ernest Cassel readership in commerce, with special reference to foreign trade, tenable at the London School of Economics and Political Science; Mr. D. Knoop to the Sir Ernest Cassel readership in commerce, with special reference to the organisation of industry and trade in the United Kingdom, tenable at the London School of Economics and Political Science; Mr. H. Dalton to the Sir Ernest Cassel readership in commerce, with special reference to tariffs and taxation, tenable at the London School of Economics and Political Science; Mr. Ll. Rodwell Jones to the University lectureship in commerce, with special reference to commercial geography, tenable at the London School of Economics and Political Science; Mr. J. D. Smith to the University lectureship in commerce, with special reference to business organisation, tenable at the London School of Economics and Political Science; and Mr. T. A. Joynt to the University lectureship in commerce, with special reference to transport and shipping, tenable at the London School of Economics and Political Science.

Grants from the Dixon Fund for 1920–21 were

made to Mr. A. S. E. Ackermann, for researches into the physical properties of clay; Mr. J. T. Carter, for researches on the minute structure of the teeth of fossil mammalia; Mr. L. T. Hogben, for researches on the influence of ductless glands; Miss M. A. Murray, for the study of anthropolgy in Egypt; Dr. F. J. North, for preparing illustrations for work in palæontology; Mr. A. K. Wells, for the conduct of a geological survey of part of Merionethshire; and Dr. C. West, for researches on the effect of environment factors on the growth of Helianthus.

The degree of Bachelor of Science in household and social science for internal students is to be instituted.

MR. P. J. HARTOG, Academic Registrar of the University of London, has been appointed Vice-Chancellor of the University of Dacca, Bengal.

DR. R. E. M. WHEELER has been appointed keeper of the department of archæology in the National Museum of Wales, and lecturer in archæology in the University College of South Wales and Monmouthshire.

WITH reference to the recent offer by the Government of a site for the University of London (see NATURE, May 27, p. 404), a largely attended meeting of the council of the University of London Graduates' Association was of the opinion that the "offer of land on the Duke of Bedford's estate, accompanied by an undefined maintenance grant now made by the Government, is in no sense an equivalent for the accommodation as at present guaranteed by the Government, and does not comply with the stipulations laid down by the Senate."

THE following bequests, amongst others, of the late Dr. Rudolf Messel have recently been published:—5000*l.* to the Royal Institution of Great Britain; 1000*l.* to the Chemical Society; 2000*l.* and his platinum still, "in which I carried out with W. S. Squire my experiments in connection with the decomposition of sulphuric acid," to Mr. Squire, requesting him on his death to leave it to the Society of Chemical Industry; his platinum crucible to the Society of Chemical Industry; and his electric telephone by Reis to the Institution of Electrical Engineers. The residue of the property is to be divided into five parts, four of which are to go to the Royal Society and one to the Society of Chemical Industry, the wish being expressed that the fund shall be kept separate from the funds of the society, the capital to be kept intact, and the whole of the income expended in the furtherance of scientific research and other scientific objects, and that no part thereof shall be applied for charitable objects, as the granting of pensions and the like.

THE first annual conference of the International Federation of University Women will be held at Bedford College, London, on July 12–14. The federation has been formed to promote understanding and fellowship between educated women of different nations, and to unite them into a league to further their common interests and to strengthen the foundations of international sympathy which must form the basis of the League of Nations. The practical means by which the federation seeks to realise its aims are: (1) Organisation of a system of exchange of lecturers and scholars of different universities. (2) Provision of international scholarships and travelling fellowships, particularly the endowment of post-graduate and research scholarships. (3) Establishment of club-rooms and hostels for international hospitality in the various centres of university life. (4) Useful co-operation with the National Bureaux of Education in the various countries. Further information may be obtained from the acting secretary, Miss T. Bosanquet, Universities Bureau of the British Empire, 50 Russell Square, London, W.C.1.

Societies and Academies.

LONDON.

Aristotelian Society, June 7.—Prof. Wildon Carr, vice-president, in the chair.—Rev. A. E. **Davies**: Anselm's problem of truth and existence. The famous proof of the existence of God is not purely ontological, but rather the verification of a specific mode of experience termed "faith." In Anselm's words, it is "faith seeking understanding," and by "faith" is meant a mode of immediate apprehension, awareness of God. Two stages are distinguishable in the reasoning. The first seeks to prove that we must think of ultimate reality in terms of existence. Here the appeal is to logical thought. In the second stage Anselm proves that this ultimate reality is his personal God. Here the appeal is to experience. The argument implies that truth and existence are two ultimate forms of reality: existence is the reality of things, truth the validity of thought-contents. Hence truth must be sought in terms of validity. This is the logical character of the "proof." We can "only *know* as perfectly as possible." We know existent reality only as our thinking is valid, and we cannot think validly that God is non-existent. Between these two ultimate forms of reality is presupposed a fundamental agreement, such that the relations of thought validly represent the real relations of things. For Anselm such agreement has its ground in God. A second implication is that when thinking is valid it starts from existence, in the same sense that its contents are occasioned by existent reality. So that without experience we cannot know. The ethical character of the basic conception of God proves it to be no mere thought-product—that is, knowledge presupposes a mode of reality dissimilar from itself.

Zoological Society, June 15.—Prof. E. W. MacBride, vice-president, in the chair.—Dr. P. Chalmers **Mitchell**: Report on the additions to the society's menagerie during the month of May, 1920.—Prof. J. E. **Duerden**: Exhibition of and remarks upon a series of ostrich eggs.—Miss Joan B. **Proctor**: (1) A collection of tail-less batrachians from East Africa made by Mr. A. Loveridge in the years 1914–19. (2) The type-specimen of *Rana Holsti*, Boulenger.—R. I. **Pocock**: The external and cranial characters of the European badger (Meles) and the American badger (Taxidea).—Dr. R. J. **Tillyard**: Life-history of the dragon-fly, with special reference to Australasian forms.

Mineralogical Society, June 15.—Dr. A. E. H. Tutton, past president, in the chair.—F. P. **Mennell**: Rare zinc-copper minerals from the Rhodesian Broken Hill Mine, Northern Rhodesia. Copper minerals, including malachite, chessylite, copper-glance, and undetermined phosphates, are of rare occurrence in the lead-zinc ore of this locality. Still rarer are the copper-zinc minerals aurichalcite and veszelyite; the latter forms minute sky-blue monoclinic crystals ($a:b:c=9{\cdot}71:1:0{\cdot}95$), and differs from the original mineral from Hungary in its colour and in containing little or no arsenic.—Prof. R. **Ohashi**: Note on the plumbiferous barytes from Shibukuro, Prefecture of Akita, Japan. This mineral, which is deposited as a white to brownish-yellow crystalline crust in the fissures and near the orifices of hot springs, is similar to the mineral recently called "hokutolite" from Taiwan (=Formosa); it contains 6·69 to 17·78 per cent. of PbO, and is radio-active.—W. A. **Richardson**: The fibrous gypsum of Nottinghamshire. The relation to the nodular types of gypsum of the fibrous veins of the mineral, which are associated with every other type of gypsum deposit in the district and occur at levels

where there is no other development of the mineral, was considered. Most of these veins are regarded as having been formed shortly after the nodular deposits. The fibres grew upwards and downwards from a plane in the marl, and were probably deposited by descending solutions, being precipitated at planes of tension in a contracting medium. The veins of fibrous calcium carbonate of "beef" described by Dr. Lang show similar structure and field relations, and doubtless originated under similar conditions.—W. A. **Richardson**: A new model rotating-stage petrological microscope. This instrument is intended as a substitute for the larger pre-war models, which at the present time could be manufactured only at very high prices. It is provided with a mechanical stage interchangeable with a plane stage and a conventional substage, and provision is made for rapid change from parallel to convergent polarised light. Owing to the reduction in size, a rotation of 270° only can be provided for the rotating stage.—W. **Barlow**: Models illustrating the atomic arrangement in potassium chloride, ammonium chloride, and tartaric acid. In the case of the chlorides the suggested structure reconciles the X-ray phenomena with the crystalline symmetry. The arrangement proposed for tartaric acid agrees with the graphical formula of the chemists, and the molecular groups have the symmetry and relative dimensions of the crystals.

Royal Meteorological Society, June 16.—Mr. R. H. Hooker, president, in the chair.—W. H. **Dines**: The ether differential radiometer. This instrument has been designed to measure the radiation from the sky after sunset. It consists of two glass test-tubes containing air and a few drops of ether connected by a glass U-shaped tube containing ether to serve as a pressure-gauge. Each test-tube is provided with a movable shield, which protects it from draughts and allows radiation from one direction only to fall upon it. It is used by first directing radiation from the sky upon one of the test-tubes, and then radiation from a "black" body at a known temperature. The known temperature is adjusted until the change has no effect upon the pressure-gauge, and when this is the case it may be assumed that the radiant energy absorbed by the test-tube from the sky is the same as that from the black body, whence the radiation from the sky is found by a table. The equivalent radiation temperature of the sky is often below 0° F., and a method is shown by which in this case the sky radiation can be found without the use of freezing mixtures. This is done by compensating the small radiation from the sky by the excess of radiation from a hot body, so that neutral effect is obtained. The method of calculation and of making up the results is given.—Prof. S. **Chapman** and E. A. **Milne**: The composition, ionisation, and viscosity of the atmosphere at great heights. In the stratosphere, owing to the absence of large-scale mixing, the different constituents of the atmosphere must tend to separate out by diffusion, so that the composition varies with the height: in particular, well-known calculations have shown that, on the usual assumption of the presence of free hydrogen, the atmosphere above 150 km. must consist almost entirely of hydrogen. The authors criticise this assumption; an examination of the evidence renders uncertain the actual existence of this hydrogen atmosphere, and the authors accordingly recalculate the variation of composition with height on the assumption that hydrogen is absent. In this case helium, the next lightest element, is the predominating constituent above 100 km. The results are then used to make an estimate of the depth to which α-, β-, or γ-radiation arriving from an extra-terrestrial source would penetrate the atmosphere. It appears that the range of α-particles would extend down to about 80 km., some 20 km. below the auroral zone. In the case of β- and γ-radiation it is found that the maximum absorption, and consequently the maximum ionisation, should occur at heights of about 50 km. and 25 km. respectively. In each case the region of appreciable ionisation would be confined to a layer of 35 km. thickness, and the unexpected result emerges that the layers would be comparatively sharply defined at their under-surfaces, which practically coincide with the positions of the maxima. These estimates have an interesting bearing on recent theories of the existence of ionised layers in the atmosphere. Lastly, attention is directed to the fact that at great heights, though the coefficient of viscosity is little altered, the density is so small that the effective viscosity is very high, so that any large-scale motion must die down immediately.

Royal Microscopical Society, June 16.—Mr. A. N. Disney, vice-president, in the chair.—L. T. **Hogben**: The problem of synapsis. The data of Mendelian experiment furnish the only critical basis for correlating genetic phenomena and cell-structure, and recent work on the cytoplasmic inclusions (Duesberg, Gatenby, and others) indicates that these elements fulfil none of the conditions which would provide a satisfactory material foundation for alternating, and in many cases biparental, inheritance of any sort. The theory of synapsis postulates the conjugation in the meiotic phase of homologous chromosomes derived from alternate parents preparatory to their segregation in the reduction division, and thus affords an interpretation of gametic purity and allelomorphism. The theory itself rests upon the assumption of the persistent individuality of chromosomes and the definitive organisation of the nuclear reticulum. The study of the meiotic phase raises three questions: (α) Is there an actual conjugation of chromosomes in the prophase? (β) If so, in what manner is it effected? (γ) Do the chromosomes which pair in synapsis separate in the reducing divisions? As regards the first, it is pointed out that the parasynaptic and telosynaptic interpretations for animals are mutually exclusive; the early meiotic phenomena in plants and animals are probably very different. With respect to the second, the question of discovering a mechanism for the interpretation of partial linkage arises. To the last question it is impossible to provide a definite answer from the available data, hence the most valuable evidence on synapsis is inferred from the different sizes and shapes of chromosome pairs in premeiotic mitoses. It is submitted, therefore, that while the cytological phenomena of hybridisation and mutation may yield significant facts, a clear recognition of the relation of the mitotic chromosomes to the organisation of the interkinetic reticulum and a fuller knowledge of the synaptic processes are the most pressing needs for further development of the chromosome hypothesis.—Sir Horace **Darwin** and W. G. **Collins**: A universal microtome. This instrument, which is designed on similar general principles to the Cambridge rocking microtome, cuts sections from objects embedded in paraffin or celloidin or from frozen preparations. It has the advantage over the rocking microtome of cutting flat sections. The plane of the sections is horizontal, which facilitates examination, and the orientating object-holder is of a novel form and easy of adjustment. The rigidity of the frame and object-holder, and the fact that the knife is rigidly clamped at both ends, secures uniformity in the sections. The microtome has no large working surfaces which must be covered with oil, hence irregularities due to varying thickness of the oil-film are eliminated.

The regularity of cutting is unaffected by wear. The rigid connection between hand and object and the smallness of the friction and inertia of the moving parts make for convenience of manipulation. The knife-holder is easily adjusted to give a slicing cut, and can also be moved so that sections can be cut with new parts of the knife as it becomes blunt or damaged. A simple accessory also enables the clearance angle of the knife to be adjusted.

PARIS.

Academy of Sciences, June 14.—M. Henri Deslandres in the chair.—The president announced the death of Prof. Auguste Righi, and gave a short account of his life-work.—A. **Rateau**: Maps of the network of electricity distribution in France. Work of the Technical Committee of the Hydrotechnical Society of France. An account of the work of the society since its establishment in 1912. Its object is the study of all questions relating to the regulation and utilisation of waterfalls. The map, on the scale of 1/200,000, will consist of eighty-four sheets, seventy-eight of which are now submitted to the Academy.—C. **Guichard**: Determination of the congruences C and the congruences 2O which belong to a linear complex.—Ch. Ed. **Guillaume**: The action of metallurgical additions on the anomaly of expansion of the nickel-steels. Certain applications of nickel-steels render necessary the addition of other elements—manganese, carbon, chromium, tungsten, and vanadium. A detailed study of the action of additions of manganese, chromium, and carbon has been made, and the results obtained have been summarised in two diagrams.—J. **Tilho**: The frequency of fogs in the Eastern Sahara. Detailed observations of these dry dust fogs are necessary, especially in the interest of aerial navigation. The results of three years' observations are given, classified as thick, medium, and light, according to the month. The fogs are relatively rare in the months between August and November.—M. Ch. Riquier was elected a correspondant for the section of geometry in succession to the late M. Zeuthen, and M. Pierre Weiss correspondant for the section of general physics in succession to Sir J. J. Thomson, elected foreign associate.—E. **Cartan**: The projective deformation of surfaces.—J. **Andrade**: The special right lines of contact of general helices.—S. **Procopiu**: The double refraction and dichroism of the fumes of ammonium chloride in the electric field. The double refraction and dichroism of ammonium chloride fumes vary with the time and differently. The double refraction varies very nearly inversely as the square of the wave-length, and the dichroism inversely as the third power. If the phenomenon predicted by Voigt exists, it is masked.—MM. **La Rosa** and A. **Sellerio**: A galvanomagnetic effect parallel to the lines of force and normal to the current.—G. **Le Bon**: Certain antagonistic properties of various regions of the spectrum. A screen of zinc sulphide placed behind a trough containing a solution of sulphate of quinine remains unaffected; if a trough of ammoniacal copper sulphate solution is superimposed, the zinc sulphide screen phosphoresces. Similar phenomena were utilised for signalling at night during the war.—J. **Meunier**: The catalytic action of aluminium in the preparation of the chlorobenzenes. Aluminium is superior to the usual catalyst, iodine, in this preparation. A weight of aluminium equal to one-thousandth of the benzene gives the best results. A detailed example of the method is given.—P. **Landrieu**: Researches on the polyacid salts of the monobasic acids: sodium tribenzoate.—R. **Blanchard**: The Durance glacier at Sisteron.—L. **Cayeux**: The iron minerals of the Longwy-Briey basin.—G. **Mangenot**: The chondriome of the Vaucheria. Further experimental evidence, both on the living plant and on fixed stained sections, in support of the views put forward in an earlier communication and adversely criticised by M. Dangeard.—E. **Saillard**: The sugar-beet during the war. The general conclusion is drawn that by using little manure, and especially little nitrogenous manures, the roots are richer in sugar and easier to work. The total production of sugar per hectare is alone affected by this abnormal culture. Similar results have been obtained in Germany.—Ch. **Porcher**: Want of food and the chemical composition of milk. A criticism of the experiments of Lami, together with additional work on the same subject. While accepting the figures of Lami, the author gives them another interpretation, and considers that the variations of chemical composition observed are due to the retention of milk and not to starvation.—P. **Mathias**: The structure of the lips of fishes of the genus Chondrostoma (family Cyprinidæ).—M. **Piettre** and A. **Vila**: The separation of the proteins of the serum. The technique proposed differs considerably from the classical methods studied by Hofmeister, Starke, Michailoff, and J. Kauder, as large quantities of mineral salts are not used. The serum is exactly neutralised, precipitated by acetone, and the albuminoids extracted with water, the last washings being saturated with carbon dioxide. The insoluble proteins free from albumin are left as a greyish-white precipitate.—G. **Bertrand** and Mme. **Rosenblatt**: The action of chloropicrin upon some bacterial fermentations. Details of experiments on the action of chloropicrin at different concentrations on the lactic ferment, the ammoniacal ferment, and the sorbose bacterium. Chloropicrin was found to exert a strongly toxic action upon all living cells, and is comparable, in some cases, with the most powerful known disinfectants.—A. **Frouin**: Variations in the fatty matters of the tubercle bacillus cultivated on definite media in the presence of earths of the cerium group.—F. **Ladreyt**: Trophic superactivity: giant cell and cancer.—MM. **Fauré-Fremiet**, **Guieysse**, **Magne**, and A. **Mayer**: Cutaneous lesions determined by certain vesicant compounds.

Books Received.

Chemical Theory and Calculations. By Prof. F. J. Wilson and Prof. I. M. Heilbron. Second edition. Pp. vii+144. (London: Constable and Co., Ltd.) 4s. 6d. net.

The Elements of Electro-Technics. By A. P. Young. Pp. viii+348. (London: Sir Isaac Pitman and Sons, Ltd.) 7s. 6d. net.

Historical Geography of Britain and the British Empire. In two books. Book i.: The Making of England: The Making of Empire: The Establishment of Empire, B.C. 55 to A.D. 1815. By T. Franklin. Pp. viii+216. (Edinburgh: W. and A. K. Johnston, Ltd.; London: Macmillan and Co., Ltd.) 2s. net.

Space, Time, and Deity. By Prof. S. Alexander. 2 vols. Vol. i., pp. xvi+347; vol. ii., pp. xiii+437. (London: Macmillan and Co., Ltd.) 36s. net.

Medical Education.

DURING the last thirty years the feeling has become increasingly insistent, both in this country and in America, that certain radical reforms were needed in the methods of education in medicine. But our American colleagues have been fortunate in having the opportunity and the means for building new schools of medicine to meet the new circumstances and for making drastic changes in their methods of teaching which a variety of circumstances has hitherto prevented us from attempting in Britain. Now that the Rockefeller Foundation, by its magnificent generosity, has made it possible for us to embark upon the difficult sea of reform, it is particularly interesting and instructive to study the policy adopted in the more advanced schools of America during the twenty-seven years since the Johns Hopkins Medical School gave the study of medicine in America a new aim and a higher ideal. Though we are a quarter of a century behind our American colleagues in making a start, our delay has given us the advantage that we can profit by the experiments made on the other side of the Atlantic.

It is not generally recognised here how thoroughly the leaders of medical education in America explored every possible method of education throughout the world, and how much devotion and thought they have expended on experiments to discover, by truly scientific methods, how best to employ the few years that the medical student can devote to the training for his profession. Those who want to understand something of the spirit and the high ideals that have inspired the American leaders in this great reform movement should read the account of their work and aims in the volume "Medical Research and Education," issued by the Science Press in New York in 1913. Briefly expressed, the matters upon which chief insistence is placed are as follows: The absolute necessity of (*a*) an adequate preliminary education and a serious University training in the basal sciences, physics, chemistry, and biology, without which foundation it is impossible for the student really to profit from his training in medical science; and (*b*) a method of practical teaching in all branches of professional work, whereby the student can, so far as possible, investigate for himself the facts and theories of each subject under the direction of men who are themselves engaged in research work, and not rely mainly upon lectures and demonstrations to give him merely the *results* of other people's work. In other words, the aim of the reform is to train the student in scientific methods rather than to "cram" him with traditional lore.

So impressed were certain American teachers with the evils of the lecture system of instruction that the attempt was made to eliminate lectures altogether. On this side of the Atlantic (and in most American schools also) it is recognised that some lectures are essential to give the student guidance and a right perspective in his work, and that demonstrations are an invaluable means of instruction, provided the student can really see the objects and appreciate the significance of the experiments. No impartial observer will, however, refuse to admit that in most British schools an altogether undue amount of the medical student's and his teacher's time is wasted in the attendance upon lectures and demonstrations of a useless or distracting kind. Several circumstances make it difficult to break with this vicious system. The financial arrangements in most of our schools are based upon payments for certain courses of lectures or demonstrations: the requirements of most institutions and examining boards are for attendance at so many lectures: and the method of awarding the Board of Education grants for some time helped still further to stereotype this system. In the American schools the student pays for his instruction, and the teacher is free to decide how best the required instruction is provided; in other words, the method of administration of the department is so arranged that the perpetuation of obsolete and vicious methods is not made compulsory for a teacher who has his own ideas as to how to educate his students to the best advantage.

The other great reform in American medical educational practice has been to bring the methods of teaching and research in the clinical subjects into line with those of the intermediate subjects.

The teachers of medicine, surgery, gynæcology, etc., used to be men practising their profession who gave up a certain amount of time to teaching medical students. Such men could bring to their teaching the ripe experience gained not only in the hospital wards, but also in contact with private patients; and, in addition to teaching the science and practice of medicine, were supposed to be able to convey to the student something of the subtle art popularly known as the "bedside manner," which is sometimes reputed to be more useful to the practitioner than either knowledge or skill. But it has long been felt that such teachers, in the course of their individual careers, would become more and more strongly tempted to neglect teaching and research as the demands of their practices became more insistent, and that it was only the exceptional man who would be sufficiently interested in investigation and teaching to make the financial and social sacrifice which the cultivation of his scientific interests would inevitably entail.

British medicine, both now and in the past, has been extraordinarily fortunate in such "exceptional" physicians and surgeons, who have deliberately set aside part of their time for scientific research and teaching. But for their zeal, this country could not have acquired or maintained its deservedly high reputation for clinical research. Nevertheless, the fact has to be faced that in some of the hospitals attached to our schools of medicine no real research of any kind is being carried on, and the clinical teaching is of the most perfunctory order. The obvious remedy for this disastrous tendency is to appoint selected men to investigate the problems of medicine and surgery and to direct the education of students, who will devote the whole of their time to this work, as the professors of anatomy, physiology, pathology, and pharmacology do at present. Such a development has, in fact, become inevitable, for now that a real science of medicine is beginning to emerge the investigation of its difficult problems and the direction of the students' training demand the whole time and energy of specially selected men with the necessary technical training and self-denying devotion to science to cope with such tasks.

This system has been tried in America with most encouraging results. Acting on the advice of Sir George Newman, the Board of Education last autumn agreed to provide financial help to enable certain medical schools to introduce the system of full-time teachers of medicine and surgery in England. Of the institutions that availed themselves of this offer, the University College Hospital Medical School was the only one which adopted a really whole-time system; and it was this consideration that focussed the interest of the Rockefeller Foundation upon the Co[illegible] School, for in America the Rockefeller Fo[illegible]on has played a large part in encouraging the a[illegible]tion of the whole-time professorships of medicine and surgery. Another factor that played some part in determining its selection was the [illegible] that University College had made provision in its Institutes of Physiology and Pharmacology for the adequate training of students in those subjects, so as to equip them to make the best use of the new facilities for clinical study in the medical school; and further that Prof. Starling had agreed to hand over to the department of anatomy the sub-department of histology, which is vitally important for the full development of teaching and research in anatomy.

The great development in the science of anatomy during the last thirty years has been due mainly to the use of the microscope for the investigation of the structure of the body and for the study of embryology. British anatomy has been hampered by the lack of the facilities for teaching these vital parts of the subject, and has suffered enormously from the lack of stimulating daily contact with them. In other countries, and especially in America, the cultivation of histology and embryology has not only made anatomy one of the most active branches of medical study and research, but also brought the work of the department into close touch with physiology, biochemistry, and pathology, to the mutual benefit of all these subjects, and especially to the student who has to integrate the information acquired in the different departments. It was the radical reforms effected in the teaching of anatomy by the late Prof. Franklin Mall at the Johns Hopkins Medical School in 1893 that played the chief part in starting the great revolution in medical education in America. The stimulating influence of the abolition of the methods of medieval scholasticism in anatomy and the return to the study of Nature and to the use of experiment brought about a closer co-operation with other departments and a general quickening of the students' interest in the real science of medicine.

The effects of these developments spread to other American schools, and the Rockefeller Foundation came to their help and contributed part of the cost of the vital reforms. In 1914 it helped the Washington University at St. Louis to build a new medical school and hospital, with full-time

professors of the clinical subjects, for the endowment of which it gave 250,000*l.*, a quarter of the cost. In 1917 it gave the Chicago University 500,000*l.*, and in ninety days the University collected a further 900,000*l.* to complete the endowment of full-time clinical chairs. In 1918 Yale University raised 650,000*l.* for the same purpose, of which the Rockefeller Foundation contributed one-quarter. In 1919 the Johns Hopkins Hospital established a full-time teaching staff in obstetrics and gynæcology, with an endowment of 250,000*l.*, of which the Rockefeller Foundation gave 100,000*l.* It is rumoured that the same Foundation, which has also given such vast endowments for medical education in Canada and China, is about to excel all its former efforts by a new scheme for further helping medical education in the United States. With such examples of the scale on which these things have to be done, surely England can do more for medical education than she is doing!

The task of the reformer of medical education is vastly more difficult in this country than in America, because on every side there is the hampering influence of cast-iron conventions; but now that the Rockefeller Foundation has helped us to begin the urgent reform there can be no doubt as to the ultimate result.

The Theory and Facts of Colour Vision.

(1) *The Physiology of Vision, with Special Reference to Colour Blindness.* By Dr. F. W. Edridge-Green. Pp. xii+280. (London: G. Bell and Sons, Ltd., 1920.) Price 12*s.* net.

(2) *Card Test for Colour Blindness.* By Dr. F. W. Edridge-Green. 24 cards. (London: G. Bell and Sons, Ltd., n.d.) Price 25*s.* net.

(1) THE great importance of the subject-matter of the volume under notice and of the card-test which supplements it is beyond all question. Interest in it is enhanced by the fact that the subject is admittedly full of difficulties. In every discussion of human sensations and of the organs which serve as the receivers of stimuli, one is impressed by the uncertainty of much which has been put forward as assured truth. It is not long ago that the mechanism of audition was being discussed anew, and even now, in spite of the renewed examination, the functions of various parts of the ear are much in debate. Yet in audition we have to deal with purely mechanical stimuli which we might have expected to have yielded up the secrets of their operation long ago. In the case of light the problem is clearly of a more recondite order, and it is not so surprising that little is actually known with certainty about the functions of various parts of the eye, and that we have therefore to fall back upon surmise.

The theory of vision most espoused by physicists is the three-colour theory of Young and Helmholtz, based upon the facts of colour mixture. It is possible to reproduce any tint whatever by mixing together three selected tints in a suitable proportion. This is accepted now by every school, and it must be taken as the basis of any theory of colour vision. The Young-Helmholtz theory explains the fact by *assuming* that there are three units in the sensitive apparatus of the eye (either three sorts of nerves or rods or cones), each of which responds in a maximum degree to one of the three primary tints, but also to a less degree to all (or most) other tints. Red, green, and blue of selected wave-lengths are taken (for reasons which cannot be given here) as the primary tints. A spectral yellow stimulates both red and green sensations, so does a mixture of red and green lights; hence a certain such mixture will produce the same sensation as does a spectral yellow. In this way the phenomena of colour mixture are explained.

Unfortunately, there are difficulties in accepting this theory. In the first place, there is no histological evidence of the existence of these three units. This objection, taken alone, is not fatal. It is conceivable that anatomical differences exist which are beyond detection with the microscope. But, in addition, there is a vast number of phenomena to be explained besides those of colour mixture, and many of these seem to be directly in opposition to the theory. Dr. Edridge-Green is well known as one who, after prolonged study of the question, was compelled to give up the trichromatic theory. The volume under review summarises the conclusions to which he has come. We can cite only a few of the experimental facts.

In certain cases of defective colour perception the yellow sensation is diminished, and in others lost altogether, although the percipient experiences three definite colour sensations (red, green, and violet). Why do not the red and green make yellow in such cases? If the eye be fatigued with pure spectral yellow light, and be then turned aside to view a spectrum, this will appear to have lost its yellow; and though yellowish-red or yellowish-green will appear less yellow, the terminal red of the spectrum will not be affected. According to the trichromatic theory,

it should be reduced in intensity. Again, the eye may be fatigued with red or green without altering the hue of spectral yellow.

If the image of a white object be suddenly formed on a portion of the retina which was previously occupied by the image of a black object, this image is surrounded by a red border. If, instead of white, a spectral greenish-yellow illumination is used, the border is colourless; if the same greenish-yellow be made up of red and green, it appears red (Bidwell).

Many dichromics have a luminosity curve similar to the normal, although their colour sensations are limited to red and blue at the ends of the spectrum, with a neutral colour in between. This would not be the case if their blindness were due to the absence of one of the sensory units (green).

The theory which Dr. Edridge-Green has developed may be outlined as follows:—

A ray of light impinging on the retina liberates the visual purple from the rods, and a "photograph" is formed.

The ends of the cones are stimulated through the photochemical decomposition of the visual purple by light, and a visual impulse is set up which is conveyed by the optic nerve to the brain.

Instead of analysing this impulse into three components, Dr. Edridge-Green regards it as an integral unit the shape of which depends upon the nature of the light exciting it.

The physicist may be reminded that he himself has already recognised that if the motions in the æther corresponding to white light could be seen, he would not be tempted to speak of them as periodic, though they are capable of being resolved by Fourier's theorem into monochromatic components. The gist of Dr. Edridge-Green's theory is that he deals with the visual impulse as a unit, but asserts (in effect) that if for convenience it is resolved into components, the number of necessary components is usually large. We do not mean that he says this in so many words; but this is, in physical language, what his statements appear to us to imply. His theory is therefore of greater generality than the restricted Young-Helmholtz theory which it supplants.

(2) The card test, which is supplementary to the text-book, consists of twenty-four cards, each containing a large number of irregular, coloured patches or spots. The shapes of these are precisely the same on all the cards, so that the examinee cannot be coached to discriminate by the form alone. These patches are differently coloured on all the cards. Each card contains a number of patches of a selected hue, different from the other patches, arranged in the form of a letter. The examinee is required to declare the letter on each card in turn. The colours are so chosen as to enable the examiner to discriminate between the different kinds of colour blindness.

We have tested them on numerous individuals. Card 8 is particularly useful in the quick detection of weakness in the green. It contains a green C and a brown S. To a normal individual the C is very prominent, while the S is a difficult letter to detect. One examinee who was quite unconscious that he was in any way defective detected the S instantly, while he could not detect the C even when his attention was directed to it.

We have not space to discuss either the book or the card test fully. We congratulate Dr. Edridge-Green on having brought together a wealth of important and interesting material on the physiology of vision.

Hydrographical Surveying.

Hydrographical Surveying: A Description of Means and Methods Employed in Constructing Marine Charts. By the late Rear-Admiral Sir William J. L. Wharton. Fourth edition, revised and enlarged by Admiral Sir Mostyn Field. Pp. xii+570. (London: John Murray, 1920.) Price 30s. net.

THE fourth edition of this work on hydrographical surveying differs but slightly from its predecessor, the main text being practically untouched, and the only important changes being the addition of several articles on newer surveying methods and experimental devices which had been introduced in the years immediately preceding the war.

Of these the description of a form of "vacuum tide-gauge," devised by Rear-Admiral H. E. Purey-Cust, a former Hydrographer of the Navy, is perhaps the most interesting, and it will certainly appeal to every nautical surveyor who has had to fight against the difficulties of observing the vertical movements of the tide in situations where direct readings are almost impossible. The addition of a trustworthy self-recorder to the instrument is obviously merely a question of time and experiment, and when it has been perfected this form of tide-gauge will undoubtedly prove an immense boon to nautical surveyors for use in those parts of the world where the ordinary methods of tide reading are impracticable.

It is to be regretted that no mention has been made of the extremely useful and convenient form of current meter known as the "Ekman." This instrument has been used with conspicuous success

by the Admiralty and by the Ministry of Agriculture and Fisheries, and is the standard form of current meter now used by both Departments.

In the new chap. xx. the "Douglas-Schäfer" sounding traveller is described on pp. 434–36, but as this is the official method of obtaining soundings in H.M. surveying vessels, it would have been more suitably placed at the commencement of this chapter than among the miscellaneous collection of methods which are largely experimental.

Several new methods connected with sweeping are now described in the new material of the book, and all have something to be said in their favour; but it is much to be hoped that the results of mine-sweeping, which developed into such a gigantic and well-organised piece of war machinery, will eventually assist in the devising of some form of thoroughly effective sweep for surveying purposes.

This last remark applies similarly to the improvement of surveying devices and methods generally. During the war such enormous progress was made in so many directions affecting scientific developments that many surveying methods must of necessity be entirely, or at least very drastically, altered to bring them up to date. The remarks under the heading "Recent Developments" on p. 470, which deal with this aspect, are, however, distinctly on the conservative

old systems must be adopted in a very wholesale manner rather than that attempts should be made at their modification to conform to the most modern methods. It is perhaps somewhat difficult to appreciate what an enormous saving of time, and, therefore, of expense and labour, will eventually result from the introduction of many of these methods into hydrographical surveying, but a good example will be found in connection with the use of hydrophones, by the aid of which accurate positions afloat can be obtained in as many hours instead of days or even weeks, which would have formerly been required under the procedure described under the heading "Triangulation by means of Floating Moored Beacons" in the new chap. xxi.

The war, in fact, has shown the necessity in this, as in so many other directions, of revising the text-books which deal with technical subjects, and this is the condition of affairs as regards hydrographical surveying. The work under notice is undoubtedly the standard publication on the subject, and has a well-deserved and world-wide reputation; but it is considered that all such standard works on technical matters, such as that now under discussion, should be prepared and published by the Government Department which is directly concerned, and, therefore, in a position to obtain the fullest information in every possible direction; and lastly, but not least in importance, which is also in a position to keep such an official work always up to date by the periodical publication of supplements.

Forestry, Tree Diseases, and Timber.

(1) *Our National Forests: A Short Popular Account of the Work of the United States Forest Service on the National Forests.* By Dr. Richard H. Douai Boerker. Pp. lxix + 238. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1918.) Price 12s. 6d. net.

(2) *Commercial Forestry in Britain: Its Decline and Revival.* By E. P. Stebbing. Pp. vi + 186. (London: John Murray, 1919.) Price 6s. net.

(3) *National Afforestation.* By A. D. Webster. Pp. 160. (London: T. Fisher Unwin, Ltd., 1919.) Price 6s. net.

(4) *Manual of Tree Diseases.* By Dr. W. Howard Rankin. (The Rural Manuals.) Pp. xx + 398. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1918.) Price 12s. 6d. net.

(5)–(8) *A Map of the World (on Mercator's Projection), Having Special Reference to Forest Regions and the Geographical Distribution of Timber Trees: Timber Map, No. 1. North America: Timber Map, No. 2. South America: Timber Map, No. 3. Europe and Africa: Timber Map, No. 4.* All prepared by J. Hudson Davies. Each on rollers, size 40 in. by 30 in. (Edinburgh: W. and A. K. Johnston, Ltd.; London: Macmillan and Co., Ltd., n.d.) Price 8s. net each.

(1) DR. BOERKER'S book is a popular account of the administration and protection of the national forests of the United States, which now constitute about a third of the timber lands in that country. The original forest area was enormous, being estimated at 850,000,000 acres. Nearly half of this has been cleared away, as the land was needed for farms by settlers; but forest fires, felling for timber, and grazing have shared largely in the destruction. To-day the land under timber trees is about 500,000,000 acres. Private ownership entailed disappearance of the forests, as no steps were ever taken to provide for the growth of a second crop of trees upon the ground. State intervention became necessary, and nothing in the political history of the United States is more creditable than the legislation of late years enforcing measures to preserve from fire and to manage

on scientific principles as much of the primeval woodlands as could be rescued from private ownership. Dr. Boerker sketches the history of this great movement.

The first effective step in conservation was the passing of an Act in 1891, which empowered the President to create forest reserves by proclamation. The first to be proclaimed was the Yellowstone Park, and others were added until they amounted to 100,000,000 acres in 1905. In that year the Forest Service was constituted as it now exists, with enlarged powers and increased appropriations from public funds. In 1907 the "forest reserves" were re-named "national forests," to do away with the impression that the timber was not to be used until some future time.

Dr. Boerker gives a list of the national forests, arranged by States, and showing the acreage of each and the headquarters of the Forest Supervisor. The national forests are nearly all in the west, comprising the higher parts of the Rocky Mountains, the Cascades, the Pacific Coast ranges, a part of the coast of Alaska, some of the hills in the Dakotas, eastern Montana, Oklahoma and Arkansas, and small areas in Minnesota, Michigan, and Florida. In March, 1915, there were 162 national forests in all, with a total area of 163,000,000 acres.

Besides the national forests, set aside out of the public lands of the west, there are mountain forests in the east, in the White Mountains and southern Appalachians, which have been gradually acquired by purchase under the Weeks law of 1911. These totalled nearly 2,000,000 acres in 1919. Under the same law the Federal Government co-operates with the States in the protection of forested watersheds, and much has been done to stop the ravages caused by fire.

In 1910 the Forests Products Laboratory was established at Madison (Wisconsin), and this great research institute has since then made signal advances in almost every phase of wood utilisation, to the great gain of the nation in times of peace and during the war. Researches have been made in wood distillation, the testing and seasoning of timber, the pulp and paper industries, tapping pines for turpentine, using wood waste, the production of artificial silk from sawdust, etc. Investigations in the industrial uses of woods have also been carried out. The attention paid to scientific research has been a significant feature of the U.S. Forest Service, as is well shown by the abundant literature on forestry subjects which has been published at Washington during the past ten years.

Dr. Boerker's book is well illustrated, and contains interesting notes on the field work in the national forests, including harvesting seed, modes of planting, diseases and insect attacks, fire protection, the building of roads, trails, and telephone lines, and the supervision of felling operations and grazing. The richness of details makes the book valuable to foresters as well as to general readers.

(2) The two small books by Mr. E. P. Stebbing and Mr. A. D. Webster narrate in a popular manner the achievements and hopes of British forestry, and are in strong contrast to the American treatise just noticed. Both authors fail notably in their historical chapters. Mr. Stebbing tries to compress into a few pages the history of the woodlands and forest policy of Great Britain from the earliest times until 1885. He bases this abstract on Nisbet's disquisition on the subject in his manual "The Forester." The fact is that the history of forestry in Britain cannot be written until it is taken up seriously, and the public records and other documents are studied and made use of.

Mr. Stebbing devotes a chapter to the various Committees and Royal Commissions appointed in the period 1885–1914 to inquire into and deal with forestry in this country. His favourable opinion of the activities of the Development Commissioners will meet with some criticism. This body did useful work from 1909 to 1914 in encouraging forestry education, but made no progress in Great Britain in the "purchase and planting of land found after inquiry suitable for afforestation," one of the main objects for which the Commissioners were appointed. The next chapter treats of the difficulties in timber supplies during the war period. In the remaining chapters Mr. Stebbing is concerned with the future of British forestry, and discusses various matters, such as the requirements of timber by Britain, what afforestation will do for the people, the connection of forestry and agriculture, the acquisition of land for planting by the State, the protection of afforested areas, etc. He is not content with the recommendations of the Reconstruction Committee for the planting of 1,770,000 acres during the next eighty years. However, we must be satisfied, in the present state of public finance, with the immense progress that has been made in the appointment last year of the Forestry Commission with a definite income and an assured programme for the next ten years. At the end of this period the problem can be reconsidered in the light of the experience gained in the meantime.

(3) Mr. Webster's small book begins with a short chapter on the history of British woodlands, which contains too little information to be of any

value. His remaining chapters deal briefly with schemes of afforestation, financial returns, trees for planting, the use of the unemployed in forestry work, the transport of timber, etc. There is nothing novel, and a good deal that is debatable, in his treatment of these subjects.

(4) Dr. Rankin's "Manual of Tree Diseases" is the first American text-book on the subject. Injuries caused by insects or other animals are not included. The first four chapters treat of general diseases, such as many species are liable to, and those affecting seedlings, leaves, stem and branches, and roots are successively dealt with. The main part of the book describes the diseases which attack various groups of trees, beginning with alders and ending with willows. Chapters on tree surgery and on spraying conclude the volume, which is fairly well illustrated. Exact and copious references to the literature of the subject are a useful feature. This manual will be of considerable use in Great Britain, although the diseases occurring here and in America are often different. The account (p. 90) of *Keithia thujina*, a dangerous fungus which has recently appeared in England and Ireland on the valuable forest tree, *Thuya gigantea*, is of considerable interest. In America it is essentially a disease of seedlings, often killing large numbers of those less than four years old. Preliminary experiments indicate that soap-Bordeaux mixture applied every ten days in autumn will greatly reduce the infection.

(5)–(8) These four maps are attractive in appearance, and will prove useful to merchants and teachers, as they show approximately the districts which yield the more important commercial timbers. Their scientific value is impaired by the fact that in a considerable number of species the areas of distribution are incorrect, and the names erroneous or confusing. For example, the small map of Old World larch is incorrect. European larch does not occur, as depicted, in the Pyrenees, Apennines, Serbia, Bulgaria, etc. The Siberian larch is wrongly styled *Larix dahurica*, whereas it is *L. sibirica* which occupies northern Russia and Siberia west of Lake Baikal. *L. leptolepis*, which is restricted to Hondo, in Japan, is represented as existing on Hokkaido, where there is no larch, and in Manchuria and Korea, where the finest *L. dahurica* grows. The small maps might readily convey more information. On the one showing Sequoia and Taxodium it would be easy to add the distribution of important timber trees like Lawson cypress, *Thuya gigantea*, and Western larch.

The author has not tried to explain by notes in the margin the peculiarities of popular nomenclature, such as the use of the term "boxwood" for the Venezuelan *Casearia praecox* (see *Kew Bulletin*, 1914, p. 214); and the application of the word "cedar" to trees so different as Cedrus, Cedrela, and Juniperus. One must acknowledge that the construction of correct maps of distribution is very difficult, as accurate information on some of the tropical woods is difficult to obtain.

Our Bookshelf.

The Natural Wealth of Britain: Its Origin and Exploitation. By S. J. Duly. (The New Teaching Series.) Pp. x+319. (London: Hodder and Stoughton, 1919.) Price 6*s.* net.

THE general scheme of this little book is decidedly good; it is intended to teach young people how the industries and commerce of Great Britain are conditioned by the geology of our island, both because the geological structure determines the sources from which we derive the materials upon which our national existence depends, and because it has produced the surface contours and configuration that have decided the lines along which our streams of commerce flow to-day. The first portion of the book gives an outline of the main principles of structural geology; then follows a section on the fundamental industries based on geological structure; and the third part deals with the geographical and geological relations of some of our most important industrial districts.

In view of the evident educational value of the plan of the book, it is all the more to be regretted that its execution is so defective. The first requisite in a text-book for young people is accuracy, and in this respect the author fails lamentably. A few random examples will illustrate the slipshod nature of the work. Thus the author, in describing granite, states that it consists of three constituents—quartz, felspar, and "the third constituent of granite comprises all the various metallic compounds." Again, a few pages further on, he tells his readers that "sapphire, ruby, aquamarine, and topaz are crystalline forms of clay."

The chapters devoted to mining are by far the worst, and it is not too much to say that there is scarcely a page that is not disfigured by some inaccuracy of more or less importance. It is impossible to imagine anyone with any real knowledge of mining writing that "the *foot-wall* beneath the coal seam is cut away . . . by *pick-axe*" (the italics are the reviewer's), or that pillars of coal "are sometimes left to support the roof." Were it not for the numerous inaccuracies of the kind indicated, this would be a most useful text-book for the general reader, but, as it is, it is greatly to be feared that he is as likely to pick up totally false impressions as to obtain useful information from its pages.

H. L.

Animal Heroes: Being the Histories of a Cat, a Dog, a Pigeon, a Lynx, two Wolves, and a Reindeer. By Ernest Thompson Seton. Fourth impression. Pp. 363. (London: Constable and Co., Ltd., 1920.) Price 8s. 6d. net.

THIS lively and generously illustrated book begins with the story of four of the lives of a "Royal Analostan" cat—we were a little afraid that there were to be nine—which, in virtue of considerable worldly wisdom, got on well against heavy odds. "But in spite of her prosperity, her social position, her royal name and fake pedigree, the greatest pleasure in her life is to slip out and go a-slumming in the gloaming, for now, as in her previous lives, she is at heart, and likely to be, nothing but a dirty little Slum Cat." The second story tells of the ability of a homing pigeon and of its successful education. "The hardest of all work is over the sea, for there is no chance of aid from landmarks; and the hardest of all times at sea is in fog, for then even the sun is blotted out and there is nothing whatever for guidance. With memory, sight, and hearing unavailable, the Homer has one thing left, and herein is his great strength, the inborn sense of direction. There is only one thing that can destroy this, and that is *fear,* hence the necessity of a stout little heart between these noble wings." This is a fair sample of the more reflective passages in the book, and it is too easy-going. There is a stronger note in the two descriptive studies of wolves, for Mr. Thompson Seton excels in proportion to the wildness of the scenery and of the *dramatis personae.* The other subjects are "The Boy and the Lynx," "The History of a Jack-Rabbit," "The Story of a Bull-Terrier," and "The White Reindeer." The author is an artist in reading the man into the beast—a great art, but a dangerous one; and we are afraid that some of the book is in the danger zone. But those who recoil from "apsychic" biology will probably agree that Mr. Thompson Seton's anthropomorphic faults lean to virtue's side.

The Year-book of the Scientific and Learned Societies of Great Britain and Ireland. Thirty-sixth Annual Issue. Pp. viii+336. (London: C. Griffin and Co., Ltd., 1919.) Price 12s. 6d. net.

As is well known, this invaluable year-book gives official particulars and records of work not only of scientific societies in the British Isles, but also of such institutions as the Imperial Institute, Meteorological Office, National Physical Laboratory, Rothamsted Experimental Station, etc. Titles are given of papers read during the session 1918–19, and twenty-six new societies have been added to the comprehensive list of those surveyed in this volume. The work is one which we continually consult, and it is an essential volume for the reference library of every newspaper, institution, college, or club which desires to provide its staff or members with accurate particulars of the officers and activities of scientific organisations throughout the kingdom.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Weather Forecasts and Meteorology.

THE experience gained during the last few years in aerial navigation has shown, among other things, that weather forecasts, in these latitudes at any rate, are trustworthy only for a few hours in advance, and not always that.

If weather forecasting were at all accurate for a day or two ahead, it would be possible to make a correct weather-chart for to-morrow from the information received to-day. This has never yet been done, and it seems unlikely that it ever can be done, for the simple reason that in latitudes higher than 30° or thereabouts the conditions of the flow of the air are those of the permanent instability which characterises a stream exposed to the influence of surface friction at a velocity greater than that compatible with lamellar flow.

The unstable motion referred to consists of eddying motion superposed on a general drift, the eddies themselves being of all sizes and in all stages of growth and decay—some showing actual rotation, others being merely distinguishable by differences of velocity and direction. Eddies, when formed, have a certain individual life, generally of not many hours' duration, though in some cases there may be maintaining causes which will prolong their existence for days. The deviations of their courses (*i.e.* the path of their centres) from the average direction of the stream depend chiefly on the state and intensity of the other eddies in the neighbourhood, and, within wide limits, must be treated as a matter of pure chance.

Let anyone watch the motes of dust in the air illuminated by a beam of sunlight passing through a slit. They may all, on the whole, be drifting in some one direction, but combined with the general drift there will be irregular eddying motions, some quick, some slow, but deviating largely from the average for the whole. Much the same sort of thing on a large scale takes place in the atmosphere, and a weather forecast professes to determine from the motion over a certain area and at a certain time, together with the then existing variations, what the future motions will be.

For a time so short that the eddying motions preserve their respective characters this can be done, but not for longer periods, the causes which alter existing eddies and develop new ones being incalculable.

If the weather prophet makes no observations whatever, but is content to say that "to-morrow will be like to-day," he will be right rather more than sixty times out of a hundred. With all the information which can be obtained, by telegraph or otherwise, he may add 10 or 15 per cent. to his correct predictions for twenty-four hours ahead.

The Meteorological Office, I believe, claims rather a better average than this, but its forecasts are often so vague (*e.g.* "Wind moderate, strong to a gale at times in places. Fair, but with some cloud and rain. Temperature moderate") that almost any sort of weather might be said to fulfil the prediction.

The proper test of the value of forecasts for a day in advance would be to prepare a chart for that day and to publish it side by side with one formed from

the actual data when they come to hand. A comparison of the two would soon show that weather prediction for more than a few hours ahead was impossible in present conditions.

While, however, long forecasts are, for the most part, mere untrustworthy guesswork, there are many meteorological subjects now neglected which might be investigated with success, but concerning which at present practically nothing is known. Such are the origin of the variation of electric potential in the air, the origin of thunderstorms and lightning, the coalescence or non-coalescence of cloud particles, the origin of hail and the causes which determine the shape and size of snow crystals or the volume of raindrops, the forms of clouds, and many others. Also there are more general questions still to be answered concerning trade winds and the circulation in equatorial regions. All investigations on these subjects should include the proper scales of comparison and attempts to produce corresponding phenomena on a small scale.

A. MALLOCK.

New University Club, June 28.

The Rate of Ascent of Pilot-Balloons.

IN NATURE for June 17 Dr. van Bemmelen directs attention to the excess rate of rising which pilot-balloons often show in the first few minutes of their ascent, and refers to two explanations of this phenomenon which have been put forward. These are that the rapid rising may be due (1) to turbulence in the lower layers of air or (2) to the tendency of balloons to be drawn into rising columns of air and thus to partake of their upward motion. The curves reproduced by Dr. van Bemmelen, which indicate the relation between rising velocity and height under different conditions, are of great interest, and show that the effect is not found when working on a small island in the Java Sea.

As double-theodolite observations over a sea exposure are not numerous, it may be of interest to refer to

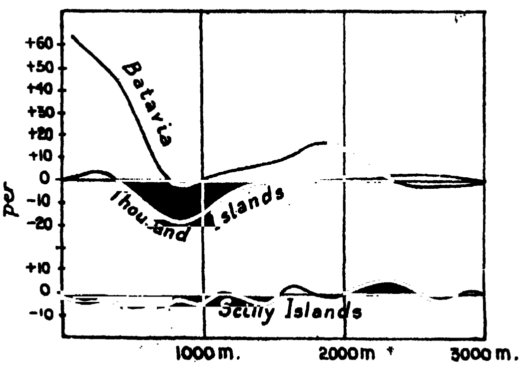

FIG. 1.

the results obtained by Capt. C. J. P. Cave and the present writer in some ascents made from the Scilly Islands during two winter months, November and December, some years ago. Particulars have recently been published by the Meteorological Office in Geophysical Memoir No. 14. The mean rate of ascent of the balloons used was found to be 160 metres per minute. Mean departures from this value for each minute of the ascent measured from the start are shown in Fig. 1. Dr. van Bemmelen's diagrams for the Thousand Islands and Batavia (0–3 p.m.) are also reproduced for comparison. It will be seen at once that the rate of ascent at Scilly, like that at the Thousand Islands, shows no excess above the normal in the first kilometre of height; if anything, the effect is slightly the other way.

Ascents in the Scilly Islands are of particular interest in this connection. The area of the islands is so small that no convection effects due to solar heating would be expected, at any rate in the winter. On the other hand, the group contains a great number of small islands of a rocky and hilly nature, and these are spread over an area of some ten miles by five. They might naturally be expected to produce some turbulence in the air passing over them, and such turbulence is, in fact, shown by the records of the pressure-tube anemometer on St. Mary's, the largest of the islands. If the excess rate of rising so frequently noticed in the first kilometre over land is due to turbulence, as suggested by Wenger, we should expect to find it in the Scilly ascents; if it is due to convection currents caused by solar heating, we should not expect to find it. The evidence afforded by this example seems clear.

J. S. DINES.

66 Sydney Street, S.W.3, June 22.

Diamagnetism and the Structure of the Hydrogen Molecule.

IN a letter to NATURE of June 24 (p. 516) Dr. J. R. Ashworth has pointed out a possible origin of the diamagnetism of hydrogen by assuming oscillations or rotations of Bohr's paramagnetic hydrogen atom or molecule. Granted that such motions tend towards a diamagnetic effect, it is important to examine the plausibility of such a view in the light of recent experimental data. We know that:

(1) The specific susceptibility (χ_H) of *gaseous hydrogen at* 16° *C.* is $-19{\cdot}8(2)\times10^{-7}\pm0{\cdot}15\times10^{-7}$, with a mean error of 0·76 per cent. (Také Soné, Science Reports, Tôhoku, vol. viii., p. 115, 1919). *No variation of this, within the limits of experiment, could be detected over a pressure range of* 1 *to* 68 *atmospheres.*

(2) The value of χ_H for *liquid hydrogen at a temperature less than* −253° *C.* is -27×10^{-7} (Onnes and Perrier, Proc. Amsterdam Acad., vol. xiv., p. 121, 1911).

(3) The value of χ_H for atomic hydrogen in various types of chemical combination, as deduced from the additive law of atomic diamagnetism for the hydrocarbons, is $-30{\cdot}5\times10^{-7}$ (Pascal, *Ann. de Chim. et de Phys.*, vol. xix., p. 5, 1910).

(4) There is no definite evidence that the diamagnetic susceptibility varies simply with temperature over a range −180° C. to 20° C. Such small variations as do occur never change the sign of χ (except in the case of tin), and are attributable to changes of molecular grouping, *e.g.* crystallisation or aggregation (Ishiwara, Science Reports, Tôhoku, vol. iii., p. 303, 1914; A. E. Oxley, Phil. Trans. Roy. Soc., vol. ccxiv., A, p. 109, 1914).

(5) The theory of molecular rotation developed by Honda and Okubo (Science Reports, Tôhoku, vol. vii., p. 141, 1918), which is similar to that proposed by Dr. Ashworth, accounts for the diamagnetism of hydrogen and helium only if we suppose molecular rotations of angular velocity $6{\cdot}54\times10^{14}\,sec^{-1}$ and $3{\cdot}80\times10^{15}\,sec^{-1}$ respectively. In the case of the paramagnetic oxygen molecule it is necessary to suppose that *there is no rotation whatsoever* in order to obtain

the hyperbolic susceptibility-temperature relationship for gaseous oxygen (Také Soné, *loc. cit.*).

(6) If the diamagnetism of hydrogen is attributed to thermal oscillations or rotations, we might expect that χ_H for the gas at 16° C. would be greater than χ_H for liquid hydrogen at −253° C. Precisely the reverse holds, according to the above data, and there is certainly no indication that at low temperature χ_H is tending to change sign.

A variation of χ_H from -19.8×10^{-7} to -27×10^{-7} for a temperature interval of 16° C. to −253° C., together with the fact that χ_H in different types of organic compounds is constant and equal to -30.5×10^{-7}, points to the conclusion that thermal oscillations and rotations have little to do with the *origin* of diamagnetism in molecular hydrogen, and that the Bohr hydrogen molecule will not account for it.

The present writer's view is that the free hydrogen atom is probably paramagnetic, but the structure of the hydrogen molecule must be such that by compensation it is, as a whole, diamagnetic. A model of the hydrogen molecule which satisfies these conditions was suggested in NATURE of May 13, 1920. In this model the individuality of the hydrogen atom is preserved, and this may have some bearing on the origin of the primary and secondary hydrogen spectra.

University Stipends and Pensions.

ALL university teachers will thank you for the leading article in NATURE of June 17 pointing out the injustice done to them and to university education by the exclusion of such teachers from the provisions of the School Teachers (Superannuation) Act, 1918. On one point, however, the article is misleading. It is stated that "what complicates matters is the fact that there exists a contributory pension scheme in the universities—the federated superannuation scheme—which is thought by some to be superior to the Teachers Act in certain respects." It should be made quite clear, however, that the governing bodies of university colleges are at liberty to adopt the federated scheme or not, and that the governing bodies of some colleges have refused to adopt it, with the result that the staffs of these colleges have no prospect of any pensions whatever. The position in the University of London is, therefore, even more anomalous than was suggested, since some schools come within the provisions of the Act, some have contributory pension schemes, and some have none. The Northampton Polytechnic Institute and the Imperial College of Science and Technology have each an engineering department the courses in which enable their students to take the B.Sc. degree of London University as internal students of the University. The lecturers of each sit side by side on the Faculty of Engineering and on the various Boards of Studies of the University. The first-named institution is included in the Teachers Act, but the last-named is excluded. Lecturers at the former retire at the age of sixty with a non-contributory Government pension, whilst their *confrères* at the Imperial College may work as long as they are able with no prospect of any pension whatever.

G. W. O. H.

THERE is nothing in "G. W. O. H.'s" letter to support his statement that the article is misleading. It is true that no university or university college is compelled to join the federated scheme, but it is equally true that such a scheme exists, and that most universities and university colleges have adopted it. The additional particulars which "G. W. O. H." gives were known to us, but obviously in a short article every variety of illustration could not be included.—ED. NATURE.

The Separation of the Isotopes of Chlorine.

IN agreement with Prof. Soddy, I find myself unable to understand how it is possible to separate isotopes by the method suggested by Mr. D. L. Chapman in NATURE of June 17. Nevertheless, a certain paradox has been brought to light in connection with Nernst's theorem the solution of which is not without interest.

The paradox to which I refer is this: Consider the equilibrium in the gaseous reaction $Cl_2+Cl'_2 \rightleftharpoons 2ClCl'$. If the gases behave as perfect gases, and if Cl and Cl′ are identical or differ only very slightly, then it is easy to show by probability considerations that the equilibrium must be given by

$$\frac{[ClCl']^2}{[Cl_2][Cl'_2]}=K=4.$$

From this it follows that to convert a gram-molecule of Cl_2 *plus* a gram-molecule of Cl'_2 into two gram-molecules of ClCl′ at the same temperature and pressure, *a* will require an amount of available energy equal to $-RT\log 4$.

Now if the chemical and physical properties of the isotopes are truly identical, then from this and the necessary equality of the vapour pressures it is readily shown that to convert a gram-molecule of solid Cl_2 *plus* a gram-molecule of solid Cl'_2 into two gram-molecules of solid ClCl′ also requires $-RT\log 4$ of available energy. Therefore the difference in the entropies of the two sets of solids is $R\log 4$, which, being independent of the temperature, must exist at the absolute zero.

It is, however, unjustifiable to say that this contradicts Nernst's theorem, and to deduce from this theorem that K for the gaseous reaction must be 1 in order to make the change in the entropy zero. For if there is a true identity, then this implies that there are no forces to guide the atoms into any particular configuration, so that even down to the zero of temperature no true reaction is possible, and what occurs is really of the nature of mixing. That a difference of entropy occurs on mixing, even at the zero, is necessary, and in no way contradicts Nernst's theorem; in fact, the case of mixtures is explicitly excluded by Nernst.

If, on the other hand, there is a real, but small, difference in the two isotopes, then, as before, K will very nearly equal 4. Now, in order to obtain the difference in the entropies between the solids near the zero of temperature, let us carry out the cycle described by Mr. Chapman, but in the neighbourhood of the zero. Then, in spite of the fact that the isotopes differ very little, it is impossible to say that the vapour pressures remain equal. Thus it is impossible, so long as there is any difference at all between the isotopes, to argue that because K=4 for the gaseous reaction there must be a finite change in entropy at the absolute zero.

The Island of Stone Statues.[1]

By SIR EVERARD IM THURN, K.C.M.G., K.B.E.

MRS. ROUTLEDGE'S account deals with her most adventurous yachting cruise, with her husband, to Easter Island, the easternmost—*i.e.* the nearest to the American coast—of that great archipelago of innumerable islands which begins off the Australian coast and ends at this islet of stone images. A considerable number of the pages of the book are occupied by a vivid and rather unusually interesting travellers' story of places visited on the outward and homeward voyages, Patagonia and the islands of Juan Fernandez and Pitcairn among others; but it is to the much fuller account of Easter Island itself, occupying one hundred and seventy-six pages of the middle of the book, that we turn most eagerly.

The mystery which surrounds the history of Easter Island, with its great statues and its unique, and perhaps for ever indecipherable, script, unparalleled elsewhere, has from time to time long attracted the attention, though very rarely the visits, of ethnologists; but in the absence of exact data the mystery has hitherto never been even approximately solved.

Mr. and Mrs. Routledge, in search of new adventure, sailed in their own small yacht, the *Mana*, to the island, spent some fifteen months there (Mr. Routledge was away from the island during a considerable part of the time), and have now given us a somewhat full account of their experiences there. The story, if far from completely satisfying, at least supplies a very great deal of material for home-staying ethnologists to study. Moreover, Mrs. Routledge holds out hopes of "another volume in prospect, with descriptions and dimensions of some two hundred and sixty burial places in the island, and thousands of measurements of statues, and other really absorbing matter." It is greatly to be hoped that this further instalment of exact data

FIG. 1.—Exterior of Rano Raraku. Eastern portion of southern aspect. Diagrammatic sketch showing position of statues. From "The Mystery of Easter Island."

[1] "The Mystery of Easter Island: The Story of an Expedition." By Mrs. Scoresby Routledge. Pp. xxi+404. (London: Sifton, Praed, and Co., Ltd., n.d.) Price 31s. 6d. net.

will be published before the great interest which has been aroused by the present foretaste has evaporated.

The most interesting points brought out in the present book are those which serve to throw partial light on the great stone statues which are so abundant in the island, and, in connection with these, on the origin of the Easter Island folk. It has hitherto generally been assumed that these folk were of Polynesian race. But recent research, by Prof. Keith and others, seems to show that, in Easter Island, as in so many of the South Sea Islands, several races with other than Polynesian culture have from time to time invaded this remote and isolated islet. Mr. Henry Balfour (in *Folklore* for December, 1917) has suggested (modestly he disclaims to have done more) some of the main results to which Mr. and Mrs. Routledge's experiences seem to point, and chiefly to the probability that at some long-distant time a strong wave of Melanesian influence reached Easter Island. Certain points of curiously strong resemblance between Easter Island arts and customs and those found in certain of the Solomon Islands serve to illustrate this.

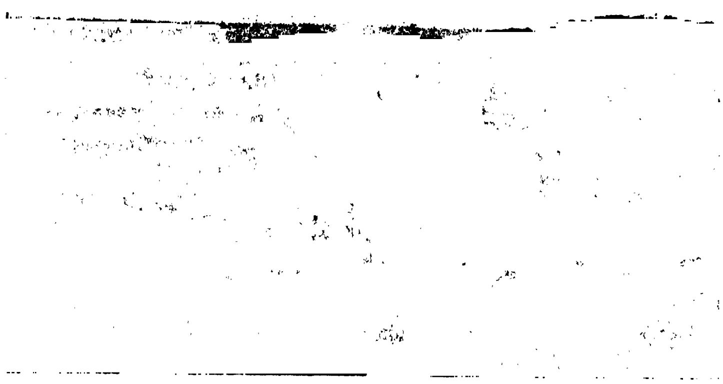

FIG. 2.—A finished Hat at Ahu Hanga O Ornu; others in the distance. From "The Mystery of Easter Island."

Without throwing any doubt on this suggestion, tentatively put forward by Mr. and Mrs. Routledge, with the strong support of Mr. Balfour and others, I again venture to put forward the view that, while Easter Island culture is doubtless of very mixed origin, Polynesian and Melanesian elements being most strongly represented, there were probably also other elements—*e.g.* some influence, possibly slight, and only very occasional, from the not far distant American shore lying to the eastward. For instance, the script (on wooden plaques), the rock-carvings, the featherwork, and the very peculiar form of tapa (bark cloth) which was used in Easter Island, all seem to me to suggest an Eastern, rather than a Western, origin.

One other suggestion may here be put forward as a contribution to the consideration of the Easter Island mystery. Mrs. Routledge writes of the well-known "top-pieces" which are, or were, superimposed on the statues as "hats"; and Mr. Balfour suggests that these were very probably meant to represent not hats, but hair, and in the number of *Folklore* above quoted he works this out in very ingenious detail. I venture to suggest a slight amendment to Mr. Balfour's proposition—*i.e.* that the stone cap-pieces in question were meant to represent not actual growing human hair, but wigs, such as those which were, and still to some extent are, commonly used by Fijians—though whether by those of Polynesian or Melanesian origin I cannot now say. It would be interesting to know how far such wigs were used in other parts of the Pacific.

It is satisfactory to know that a second edition of Mrs. Routledge's book is already in course of preparation, and all ethnologists must hope that the full scientific data will also soon be published.

The Blue Sky and the Optical Properties of Air.[1]

By the RIGHT HON. LORD RAYLEIGH, F.R.S.

Scattering by Small Particles. Polarisation.

THE subject chosen for this evening is one which specially interested my father throughout his career. I shall try to put before you some of his conclusions, and then pass on to more recent developments, in which I have myself had a share.

Let us begin with one of his experiments which illustrates the accepted theory of the blue sky. We have here a glass tank containing a dilute solution of sodium thiosulphate. A condensed beam from the electric arc traverses it and then falls on a white screen, where it shows the usual white colour. I now add a small quantity of acid, which decomposes the solution with slow precipitation of very finely divided particles of sulphur. As soon as this precipitation begins you see that light is scattered—that is to say, it is diverted to every side out of the original direction of propagation. Moreover, you will observe that the

1 Discourse delivered at the Royal Institution on Friday, May 7, 1920.

scattered light is blue. The transmitted beam is robbed of its bluer constituents, and tends to become yellower, as you may see on the screen.

The light scattered laterally is to be compared to the blue sky; the yellow transmitted light to the direct light of the setting sun when it has traversed a great thickness of air.

As the precipitation goes on, the transmitted light becomes orange, and even red. But the particles of sulphur eventually get bigger, and then give a less pure blue in the lateral direction. We shall have more than enough to occupy us if we confine our attention to the earlier stages, when the particles are small compared with the waves of light.

A very important property of the scattered light is its polarisation. The vibrations of the scattered light as you have seen it, viewed laterally in the horizontal plane, are almost wholly up and down. No light is emitted which vibrates in the horizontal plane. It is easy for individual observers to verify this with a Nicol's prism held to the eye, but this direct method unfortunately does not lend itself to public demonstration.

We may, however, use polarised light to begin with, and you can then observe that if the polarising Nicol is set so as to transmit up and down vibrations, these are abundantly scattered towards you by the small particles. As I turn the polarising Nicol through a right angle, you will see that the light scattered towards you is extinguished.

The polarisation of light scattered by the sulphur particles is one of the most conclusive reasons for considering it to be an analogue of the blue light of the sky, for the latter shows a polarisation of exactly the same kind when examined at right angles to the sun.

A cloud of small particles of any kind is capable of producing these effects, the essential condition being that the individual particles should be of small dimensions compared with the wave-length of light, so that at a given moment the vibration at a given particle may be regarded as having a definite phase. In this case it was shown by my father that the shorter (blue) waves are of necessity more scattered than the longer ones (red); thus the scattered light is bluer than the original. This conclusion can be justified in detail whether we adopt the elastic solid theory, or the electromagnetic theory of the nature of light, but it is also deducible from the general theory of dimensions, without entering upon any details of the nature of light beyond its characterisation by the wave-length.

An alternative theory which still sometimes shows its head attributes the colour of the sky to a blueness of the air, regarded as an absorptive medium. Such blueness is referred to the presence of ozone, and appeal is made to the undoubted fact that a sufficiently thick layer of ozone shows a blue colour by absorption. This theory gives no account of why the sky light is polarised, or indeed of why there is any light in the clear sky at all. Further, its fundamental postulate that the air is blue by transmission is contrary to observation. The setting sun is seen through a greater thickness of air than the midday sun. According to the theory under discussion, the setting sun ought to be the bluer of the two, which everyone knows it is not. No doubt the presence of ozone tends to make the air blue by transmission. But this effect is more than compensated by the lateral leakage (scattering) of blue light from the beam, which makes the transmitted light yellow.

Dusty Air and Pure Air.

If it be conceded that the blue sky is due to scattering by small particles, we are confronted with the question: Of what nature are these particles? At the time of my father's early investigations (1871) this was left open, though they were regarded as extraneous to the air itself. In 1899 he returned to the subject, and considered the matter from the point of view of what was lost by the original beam by lateral leakage (scattering), which simulates the effect of absorption. He then found that the air itself, regarded as an assemblage of small particles (molecules of oxygen and nitrogen), would have an apparent absorbing power not much less than that actually deduced by observations of the sun at different altitudes. The inference was that the air itself was capable of accounting for much, if not all, of the scattering which is observed in the blue sky; in fact, that the molecules of air are the small particles in question.

When a beam of sunlight enters a room through a small aperture in the shutter, its course is readily traced by the brightly illuminated motes in the air. Prof. Tyndall, working in this institution, devoted much attention to the nature of these motes, and the methods by which they may be got rid of. His results may be consulted in his fascinating essay on "Floating Matter." One way of getting rid of the motes is to filter the air through cotton-wool. We have here one of Tyndall's own experimental tubes. The electric beam passes axially along it, and is concentrated to a focus about the middle of its length. Its track is conspicuous. If now we displace the air originally in the tube by filtered air, you see that the cone of light fades into invisibility.

Another of Tyndall's experiments was merely to place a spirit lamp or Bunsen burner under the beam. Since most of the dust particles are combustible, the gases rising from the flame are free from them. As you now see, dark rifts appear in the beam where the uprising stream of dust-free gases traverses it.

Tyndall, on the strength of these experiments, stated without qualification that dust-free air does not scatter light, but my father's views and theory lead clearly to the conclusion that it does. But when I asked him what he thought about the feasibility of detecting it by a laboratory experiment, he was not very sanguine of success. It seemed worth while, however, to make the attempt, and I came to the conclusion that the difficulty was not

so much in the faintness of the effect to be looked for as in the avoidance of stray light which came into competition with it. The essential thing is to get a perfectly black background against which the beam (viewed transversely) can be observed. We cannot get this with a vessel like Tyndall's tube just used. It is necessary to have what may be called a black cave, and to view the beam as it crosses in front of the mouth of the cave, the latter forming the background. If the cave is deep enough, there is no limit to the blackness attainable. The great sensitiveness of the well-rested eye, or the photographic plate, can then be brought to bear, and the track of the beam can be well seen, however carefully the dust is removed.

Some persons have been inclined to question whether the dust is removed completely in these experiments. As a matter of fact, this is not where the difficulty lies at all. Dust so fine as to be very difficult of filtration is an arm-chair conception, not encountered in practical experimenting. An enormous multiplication of the length and tightness of the cotton-wool filter makes no difference at all, a filter of modest dimensions doing all there is to do.

The dust particles which are originally present in the air, near the ground or in a room, are large, being in some cases individually visible to the naked eye; thus they do not fulfil the condition for scattering a preponderance of blue light. The molecules of air are, of course, amply small enough, and the band of light seen stretching across the mouth of the dark cave is, to my eyes at least, of a full blue colour. In exhibiting the effect to individual friends (and unfortunately it is not bright enough to be shown to an audience), I have been surprised and somewhat disconcerted to find that they do not all see it blue as I do, but some, for example, describe it as lavender. This is undoubtedly due to a peculiarity of colour-vision where faint lights are concerned. The ultimate test is the spectroscope. Photographs of the scattered light taken with this instrument clearly show that the maximum of intensity is shifted towards the blue, as compared with the original exciting light.

Polarisation of Light Scattered by Pure Air.

A very important point to examine in connection with the scattered light is its state of polarisation. Visual examination with a Nicol's prism soon showed that the polarisation was very nearly complete. For closer examination I had recourse to photography. It may perhaps be thought an easier and more effective plan to look at a phenomenon than to photograph it, and no doubt it is so in many cases: not, however, where the light is very faint, but admits of long exposure. It has long been recognised that photographs of the nebulæ will show much more than can be detected visually by the keenest and most discriminating eye. In this work on the scattering of light, I have found it positively less trouble to take a photograph than to make a visual observation, even when the latter was feasible. The time required to rest the eye in darkness and the effort of attention required in observing a faint effect cost the experimenter more than the exposure and development of a plate.

When the scattered beam in pure air is photographed, with a double image prism of Iceland spar mounted over the photographic lens, it is found that the polarisation is nearly complete, but not absolutely so. However carefully the instrumental adjustments are made and the air filtered, I have found that there is a slight residual polarisation indicating vibrations parallel to the direction of the original beam. The intensity of this residual polarisation, in what may be called for convenience the wrong direction, is about 4 per cent. of the whole. Now, as the theory shows, there are two causes to which failure of complete polarisation may be attributed. One, which we may dismiss in this case, is that the particles are not small enough. Another is that they are not spherical—that is to say, it is not a matter of indifference which way they are presented to the primary beam. The latter alternative may be illustrated by considering an extreme case—namely, what we may call a needle-like molecule, capable of vibrating only in one direction fixed within it. Evidently such a molecule when obliquely situated will have a component vibration parallel to the direction of the incident light.

From the experimental fact that there is such a component we may infer that the molecules of air are not in the optical sense spherical. Experiments on various gases have shown a characteristic departure from complete polarisation, different for each gas. Much effort has been spent on determining the exact amount for each, and it is hoped that the numbers obtained will form valuable material in the future for investigating the structure of atoms and molecules.

Polarisation of the Night Sky.

We have seen that the polarisation of the daylight sky is one of the most conclusive proofs that its light is due to scattering by small particles. What of the sky at night? Some of you will perhaps be inclined to reply that the sky at night is dark, and that the question whether its light is polarised does not arise. It is, however, by no means the case that the sky on a clear night is absolutely dark, as anyone may readily prove by holding his hand with outstretched fingers against the sky. The fingers will appear dark against the sky as a luminous background.

The light is no doubt very faint, but I thought it would be practicable to test whether it was appreciably polarised or not. For this purpose what is called a Savart polariscope was used. Time will not allow us to consider the rather complex theory of this apparatus; it must suffice to say that if the light which falls upon it contains even a small part which is polarised, bands alternately bright and dark are produced, which further show colour due to the composite nature

of white light. These bands are clearest when the incident light is completely polarised, as you now see them projected on the screen. But they can still be seen when the polarisation is but slight. I will illustrate this by removing the polarising Nicol which I have been using, and substituting a single glass plate, through which the incident light passes. If I incline this plate so as to polarise a small fraction of the light, you see the bands, faint but sufficiently distinct. In examining the light of the night sky, a photographic plate is substituted for the paper screen I have been using to-night, and the apparatus is designed for the utmost economy of light. With two hours' exposure a definite image of the sky was obtained, with the stars superposed upon it. The Savart bands could be seen, but they were very faint compared with what would have been observed with an equally good image of the daylight sky. The part of the sky examined was near the pole, and therefore nearly at right angles to the sun. If, as seemed possible, the night sky derived its light from an attenuated atmosphere so high as to be outside the earth's shadow, we should expect it to show the same polarisation as the day sky. Since it does not do so, we must attribute the light at night to some different origin.

I was fortunate in being able to interest Prof. Hale in this matter while he was on a visit to England, and as a result Mr. Babcock repeated the observations in a modified form at the Mount Wilson Observatory in California. The traces of polarisation which he obtained in that clear atmosphere were even less than what I got in England.

Ozone, and the Limit of the Solar Spectrum.

Although, as we have seen, the idea that the blue colour of the sky is due to any action of ozone cannot be admitted, yet there are points of great optical interest connected with the presence of this gas in the atmosphere. We may now turn to the consideration of some of these.

It is of course well known that when the solar spectrum is formed by a prism of quartz or by a grating, the spectrum can be observed to extend beyond its visible limit in the violet into the region called ultra-violet. When, however, we examine the spectrum of an electric arc (and for this purpose an iron arc is particularly suitable), the extension is observed to be very much greater than in the solar spectrum. This is not because the sun does not emit any rays of the kind in question, but because the earth's atmosphere will not allow them to pass through so as to reach us at the earth's surface. There are many reasons for feeling sure that this is the true explanation, but one of the simplest will here suffice. When the sun is near the horizon, so that the rays pass obliquely through the earth's atmosphere, and consequently have to traverse a thicker absorbing layer, the extent of the ultra-violet spectrum is found to be even less than when the sun is high and less air is traversed by the rays. This sufficiently proves the point.

It has long been suspected that ozone in the atmosphere is the effective cause of this absorption of the ultra-violet rays. The most important constituents of air, oxygen, and nitrogen do not appreciably absorb at the point where the solar spectrum ends, nor do the constituents of secondary importance, carbonic acid, water-vapour, and argon. We must therefore look to some rare constituent of air which is very opaque to this region of the spectrum. Ozone possesses this opacity, as I shall now show you. So far as I know it has not been attempted to show this before to an audience, but I think you will be able to see it without difficulty. As a source of light an iron arc is used, and the lenses and prism employed in forming the spectrum are of quartz. I allow the spectrum to fall on a piece of paper, and you see the usual succession of colours, red, yellow, green, blue, and violet, forming a comparatively narrow rainbow-like band. Beyond the violet all appears dark, the eye being insensitive to the ultra-violet rays. If now I substitute for the paper a screen of barium platinocyanide[2] (of the kind used in X-ray work), we see an immense extension of the spectrum beyond the violet. The screen has the property of transforming the ultra-violet rays, which the eye cannot detect, into green rays which are readily visible. Thus beyond the violet region we see green, which is, of course, in no way to be confused with the original green which was present in the source. and appears in its normal position in the spectrum, on the other side of the blue-violet. I interpose a thin sheet of ordinary glass, and the greater part of this extension of the spectrum which we get on the fluorescent screen disappears. What I want specially to show you, however, is that a thin layer of ozone, much too thin to have any perceptible colour, will have the same effect. There is a glass tube, about 6 in. long and $\frac{3}{4}$ in. in diameter, situated between the quartz lantern condenser and the slit, when the beam is parallel, and the walls of the tube are projected as two thin transverse lines on the slit, dividing the spectrum into thin horizontal strips, one over the other. The light constituting the middle strip has traversed the tube, but the light constituting the upper and lower strip has traversed the open air above and below the tube. A stream of oxygen passes through a Siemens ozone generator and enters the middle of the observation tube, streaming out at the two ends. While the ozone generator is not excited, the middle strip of the spectrum is similar to the comparison strips above and below. If the induction coil is turned on so that ozone passes into the tube, you see that in a few seconds the greater part of the ultra-violet spectrum fades out from the middle strip, which contrasts sharply with the upper and lower ones. When the coil is turned off, the ozone is rapidly blown out by unozonised oxygen, and the original state of things restored.

It must be remembered that the ozone used in this experiment is extremely dilute, probably only a fraction of 1 per cent. of the oxygen in the tube.

[2] Kindly lent by Messrs. Watson.

Yet it interposes an impassable obstacle to the ultra-violet rays, at least to those of shorter wave-length than about 2900 angstroms. It cuts off the iron spectrum at about the same point where the solar spectrum ends. Speaking roughly and generally, it may be said that glass is somewhat more opaque than ozone—*i.e.* that with diminishing wave-length the limit of transmission is reached somewhat sooner. To make a statement of this kind quite definite the thickness must of course be specified.

Sir William Huggins devoted a great deal of attention to the spectra of the sun and stars in the extreme ultra-violet region, using for the purpose a reflecting telescope, and prisms and lenses made of quartz or Iceland spar. In this way the absorption of a glass objective was avoided. He noticed in 1890 that the spectrum of Sirius showed a number of bands near the extreme limit of atmospheric transmission, the bands tailing off into complete absorption.

These bands were observed and discussed by other authors, but no definite conclusion was reached as to their origin until 1917, when the matter was taken up by my colleague, Prof. Fowler, and myself. Our interest was stimulated by an excellent photograph of the bands, taken at Edinburgh Observatory under Prof. Sampson's direction, which I show on the screen. We found that the same bands were present in the solar spectrum. It may seem strange that this had not been observed long ago, considering how closely the solar spectrum has been scrutinised for more than a generation. As a matter of fact this is one of the cases where a powerful instrument is a positive disadvantage. The bands are diffuse, and under high dispersion they are unrecognisable. In any case, they are less conspicuous than in the spectrum of Sirius, because in the sun numerous metallic lines are superposed upon them and distract the eye.

Now the position and general aspect of these bands suggested that they were connected with the absorption which terminates the spectrum. This led us to suspect that they were due to ozone, and the suspicion was readily confirmed by experiment. Burning magnesium ribbon gives a convenient source of continuous spectrum in the ultra-violet region. Interposing a long tube containing ozone between the burning magnesium and the slit, a series of bands was photographed which exactly corresponded to those photographed in the solar spectrum with the same instrument, as you will see in the slide shown.

Absence of Ozone near the Ground.

We are then driven to the conclusion that the absence of short waves from the spectra of the sun and stars is due to absorption by terrestrial ozone. But it was not thought desirable to let the matter rest there. It is true that many attempts had been made to determine the (no doubt very small) quantity of ozone in air by chemical means, but with very conflicting results, because other constituents of air, such as oxides of nitrogen, are liable to produce reactions not unlike those of ozone. It seemed more satisfactory to test the absorbing power of air near the ground for ultra-violet rays, to which ozone is so opaque. I used for this purpose a mercury vapour lamp in a quartz vessel, which is a powerful source of ultra-violet rays, and observed its spectrum four miles away, so that the mass of air intervening was as great as that between the midday summer sun and the top of the Peak of Teneriffe, from which observations of the extent of the solar spectrum have been made. The result was to show that the mercury lamp spectrum was by no means stopped when the solar spectrum stops, but that it extended to the region where ozone is most opaque. There is a strong mercury line (wave-length 2536) at about this point which was distinctly photographed. Its intensity was of course a good deal reduced relative to the visible spectrum by atmospheric scattering. But there was no evidence whatever of ozone absorption.

What conclusion can we draw? Evidently that the absorbent layer of ozone in the air is high up, and that there is little or none near the ground. It may seem at first sight that this thin and inaccessible layer of ozone, which we have learned of by a chain of reasoning not less conclusive than direct observation, is a matter of little importance to man and his welfare. There could be no greater mistake. It acts as a screen to protect us from the ultra-violet rays of the sun, which without such a protection would probably be fatal to our eyesight: at least if one may judge from the painful results of even a short exposure to such rays, which those who have experienced it are not likely to forget.

The Future of the Iron and Steel Industry in Lorraine.

By PROF. H. C. H. CARPENTER, F.R.S.

DURING the spring of last year two Commissions were appointed by the Minister of Munitions to visit and report upon certain steel-producing areas in Western Europe. One of them visited the steel works in Lorraine and certain parts of the Saar Valley, the other journeying to the occupied areas of Germany, Luxemburg, and certain parts of France and Belgium. The former was under the charge of Sir William Jones, and included Messrs. Percy Cooper, Rowland Harding, and Cosmo Johns, while the latter was entrusted to Dr. F. H. Hatch, who had with him Messrs. L. Ennis, James Henderson, and Richard Mather. The Commissions were absent about three weeks. The terms of reference to them were the same and were to ascertain:—

(a) The character and extent of the technical and other developments which had taken place during the war, with special reference to the steps taken for the development of munitions output.

(b) The present condition of plant and machinery.

(c) The prospects of these areas either as competitors with or markets for British industries.

(d) The developments in fuel economy in the steel trades of these areas.

The reports furnished by the Commissions were printed in the first instance as confidential documents by the Ministry of Munitions, but have now been made public. That of the Commission which visited Lorraine and the Saar Valley is the more complete and interesting in that it throws light on the possibilities of development of the iron- and steel-producing area, which, as a result of the war and the Peace Treaty, has passed from German to French ownership.

The view of the Commission is that the acquisition by the French of these areas should be of advantage to British industries on the whole, and that while France may become a competitor with Britain in so far as her surplus steel production is concerned, taking the place of Germany to some extent, it will not be until the destroyed works have been reconstructed and full production has been reached in a period which it estimates at from three to five years. As a result of the war, France has replaced Germany as the possessor of the largest iron-ore supplies in Europe, her reserves having been increased by more than 2,000,000,000 tons, making them now about four times those of Germany. Before the war they were approximately the same.

Whereas France's production of pig iron in 1913 was about 5,000,000 tons, with her new possessions in Lorraine and the Saar Valley she is in a position to produce 11,000,000 tons annually. Prior to the war German steel makers frequently complained of the difficulty of obtaining adequate supplies of foreign ores, and this is regarded by many as one of the chief causes of the war, since they hoped thereby to obtain possession of France's ore reserves. The Commission states that whereas in 1913 Germany produced 27,000,000, and France 21,000,000, tons of iron ore, it estimates future production to be in the ratio of Germany 7,000,000 to France 42,000,000 tons. It would appear that outside France Germany can expect to obtain ore only from Sweden or Spain, but as both these countries are actively developing their steel industries they will probably not have very much to spare.

With regard to coal, however, France's position is by no means so satisfactory. Her pre-war production was about 40,000,000 tons, and her consumption 60,000,000 tons, the balance being obtained from Great Britain, Belgium, and Germany.

The control by France of the coal of the Saar Valley area is estimated to enable her to produce twice the tonnage obtained from the Valenciennes district. This would mean an addition of 17,000,000 tons to the annual output, which nearly meets the deficit. The Commission states, however, that the ideal of the French iron and steel makers in the Lorraine area at the present time is that means should be devised whereby a reciprocal business may be done with Great Britain by their supplying basic pig iron in exchange for furnace coke or coking coal. If the anticipated output of oven coke in this country is realised there should be some to spare, but the difficulties of transport, transhipment, etc., and the resultant breakage are serious factors to be considered. Possibly the solution of the present problem may be found in the erection of coke ovens in Lorraine close to the furnaces, and in the production of coke on the spot from a mixture of Saar coal and Durham coking coal. The supply of the latter cannot take place until better and cheaper means of transport are available.

The Commission states that France dreads the present position of dependence upon Germany for coke supplies, since, although the Peace Treaty gives her control of the Saar Valley coalfield for, at any rate, fifteen years, the fact remains that under existing conditions the works must have coal or coke from Westphalia for their blast furnaces. The coke obtained from Saar coal is apparently unsatisfactory, so that so long as this position continues French industry will remain to a great extent at the mercy of the Germans, a position the French are, naturally, most anxious to avoid. It is true that Germany will want iron ore from Lorraine, but she will not be so entirely dependent upon this one source of supply as the Lorraine works will be upon Germany for coke, unless some means are provided to enable them to obtain coke from elsewhere or to produce what they need from Saar coal and imported coking coal.

Various schemes for improved transport are under contemplation by France. The construction of a canal to Dunkirk from the Briey district known as the "Canal du Nord et de l'Est" has been under consideration for a long time. This would take at least five years to complete, and is not generally favoured by the French steel makers in Lorraine owing to the enormous cost of construction and the great difficulties to be overcome in cutting it through the densely populated industrial areas of Northern France. The scheme most favoured is that known as the canalisation of the Moselle from Coblenz to Thionville and thence to Metz, coupled with free navigation of the Rhine to Rotterdam or by canal from the Rhine to Antwerp *via* Maastricht. Either of these schemes, it is considered, would be much cheaper and more quickly operative than the canal to Dunkirk. The estimate of the cost of the Moselle Canal scheme would be between 15,000,000*l.* and 20,000,000*l.*, and it is calculated that the construction could be completed in three years. Plans for this scheme are in the hands of the French authorities. The strong feeling in favour of this scheme to enable reciprocal business to be done with Great Britain is accentuated by the treatment

accorded to the Lorraine steel works by Germany in the matter of coke supplies, since the Germans have failed to carry out their obligations under the terms of the Peace Treaty, and have delivered only about one-third of the tonnage promised, notwithstanding the fact that there are large stores of furnace coke in Westphalia. Since Great Britain has been short of basic pig iron for a long time, and there is every prospect of the shortage continuing, some such reciprocal arrangement as that put forward might be of advantage to both countries.

The Commission states that there is no doubt that economy in fuel consumption is very fully effected, owing to the absence of cheap and suitable fuel and the dependence of the works upon Westphalian coke. All the waste heat is utilised at every works. The blast-furnace gas is suitably cleaned and fully absorbed. The works at Homécourt may be cited as an instance. Before the war they were producing 9000 tons of pig iron and 7000 tons of steel weekly, and they used only 280 tons of coal, all the remaining power being produced from blast-furnace gas. This is quite typical. The molten metal is taken from the blast furnaces to the mixers in the adjacent steel works and the sensible heat thus utilised.

A study of the report leaves the impression that the development of the iron- and steel-producing areas in Lorraine which have passed from German to French management presents problems which will call for patient consideration, dispassionate counsel, and scientific treatment, if they are to be surmounted successfully. The formidable position which Germany had built up between 1871 and 1914 has been lost to her by the war. It remains to be seen what France will make of the heritage which has passed into her hands.

Obituary.

WE regret to note that the death of MR. JOHN W. W. DRYSDALE is recorded in the *Engineer* for June 25 as having occurred on June 21. Mr. Drysdale was in his seventy-second year, and was one of the founders of the well-known Glasgow firm of Drysdale and Co., Ltd. He finished his education at Glasgow University under Prof. Macquorn Rankine, and thereafter started a small works in conjunction with a fellow-student, Mr. Lewis J. Pirrie, son of Principal Pirrie of Aberdeen. Centrifugal pumps formed their outstanding speciality from the first, and the firm has acquired a wide reputation for its products. Mr. Drysdale was a member of the Institution of Engineers and Shipbuilders in Scotland.

WE announce with great regret the death, at the Queen Alexandra Military Hospital, Millbank, of SURGEON-GENERAL W. C. GORGAS, of the U.S. Army, so well known for his work in combating yellow fever and malaria.

Notes.

THE Lord President of the Council, as president of the Committee of Council for Scientific and Industrial Research, has appointed Dr. J. S. Flett, at present Assistant to the Director in Scotland, to be Director of the Geological Survey and Museum. Dr. Flett succeeds Sir Aubrey Strahan, who retires this month. Mr. G. W. Lamplugh, Assistant to the Director in England, also retires.

SIR JOHN CADMAN, Mr. W. B. Hardy, and Prof. S. Young have been appointed by an Order in Council members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research.

IT is announced that Sir T. Clifford Allbutt is to be sworn a member of the Privy Council.

THE secretaryship of the Royal Irish Academy, vacant through the death of Prof J. A. McClelland, has been filled by the election of Prof. G. H. Carpenter.

THE Barnard medal of Columbia University has been awarded to Prof. Einstein "in recognition of his highly original and fruitful development of the fundamental concepts of physics through the application of mathematics."

DR. E. SOLVAY has been elected an honorary member of the American Chemical Society.

THE Medical Research Council has recently established at the Lister Institute of Preventive Medicine a national collection of type cultures from which biologists in general, and bacteriologists in particular, may obtain authentic strains of recognised bacteria and protozoa for use in scientific work. The scheme is under the general direction of Dr. J. C. G. Ledingham, while Dr. R. St. John Brooks has been appointed to the post of curator of the collection and Miss Mabel Rhodes to that of assistant curator. It is proposed to collect and maintain bacterial strains from all departments of bacteriology, human, veterinary, and economic, and already considerable work has been done towards the formation of a representative collection on these lines. The efforts of the staff are, however, at present particularly directed towards the securing of fully authenticated strains responsible for or associated with disease in man and animals. The bureau proposes to supply cultures on demand to all workers at home and abroad, and, as a rule, a nominal charge per culture will be made to defray postage and media. Strains sent for identification and maintenance should be accompanied by particulars as to source, date of isolation, etc. In due course a catalogue will be prepared for publication.

IN NATURE of January 1 last an account was given of the Cawthron Institute of New Zealand, founded for the furtherance of scientific research in relation to agriculture and other industries. The scope of the institute has since been extended by the establishment of a biological department, of which Dr. R. J. Tillyard, the eminent Australian entomologist, hitherto

research fellow of Sydney University, has been appointed chief. He will be assisted by Miss K. M. Curtis as mycologist and Mr. A. Philpott as assistant entomologist. We understand that members of the scientific staff of the institute will have full freedom as to research and publication.

A COMMITTEE, composed of the following members, has been appointed by the Ministry of Health to consider and report on the legislative and administrative measures necessary to secure adequate protection for the health of the people in connection with the slaughter of animals and the distribution of meat for human consumption in England and Wales:—Sir H. C. Monro (chairman), Mr. W. G. R. Boys, Mr. R. B. Cross, Mr. J. Edwards, Dr. W. J. Howarth, Dr. A. W. J. MacFadden, Mr. T. Masheter, Mr. A. W. Monro, Mr. T. Parker, Mr. R. J. Robinson, and Mr. P. Taylor. Mr. H. F. O. Jerram is the secretary of the Committee, and communications should be addressed to him at the Ministry of Health, Whitehall, S.W.1.

IT was stated by Mr. Bonar Law in the House of Commons on Monday last, with reference to the question of scientific war inventions, that the Lord President of the Council is about to appoint an inter-Departmental Committee with the following terms of reference:—(1) To consider the methods of dealing with inventions made by workers aided or maintained from public funds, whether such workers be engaged (*a*) as research workers or (*b*) in some other technical capacity, so as to give a fair reward to the inventor and thus encourage further effort, to secure the utilisation in industry of suitable inventions, and to protect the national interest; and (2) to outline a course of procedure in respect of inventions arising out of State-aided or supported work, which shall further these aims and be suitable for adoption by all Government Departments concerned.

A SPECIAL meeting of the Röntgen Society is to be held at University College, Gower Street, at 9 o'clock on Thursday evening, July 15, when an address will be delivered by Dr. W. D. Coolidge, of the Research Laboratories of the General Electric Co., Schenectady, New York. An invitation to the meeting is given to the members of other scientific and medical societies.

A FREE public lecture on "Oil Storage, Transport, and Distribution" is to be delivered by Mr. H. Barringer at 6 o'clock on July 14 in the Canada Building, Crystal Palace, under the auspices of the Institution of Petroleum Technologists. The institution has also arranged for the delivery of four lectures, as follow, in September, the actual dates for which will be announced later: "Oil Prospecting," Mr. G. Howell; "Petroleum Refining," Dr. A. E. Dunstan; "Utilisation of Volatile Oils," Dr. W. R. Ormanby, and "Utilisation of Heavy Oils," Prof. J. S. S. Brame.

THE annual Oxford Ophthalmological Congress will take place in the Department of Human Anatomy in the University Museum, Oxford, on July 15 and 16. Among the promised communications are the following: The Doyne memorial lecture, by F. R. Cross, on "The Nerve Paths and Centres concerned with Sight": A. S. Percival, "Light Sense"; Dr. Van der Hœve, "Eye Symptoms in Tuberose Sclerosis of the Brain"; Dr. L. C. Peter and others, "Perimetric Methods"; M. Barton, "Examination of the Eyes of Pit Ponies, particularly with reference to Miners' Nystagmus"; A. H. Thompson, "Physiological and Glaucoma Cups"; R. D. Batten, "Premonitory Symptoms of Glaucoma"; and Dr. L. Sambon, "Ancient Eye Instruments."

THE Research Association for the Silk Industry has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The secretary of the committee engaged in the establishment of this association is Mr. A. B. Ball, the Silk Association of Great Britain and Ireland, Kingsway House, Kingsway, W.C.2.

THE jubilee of the American Fisheries Society will be celebrated at Ottawa on September 20–22 next. In connection with the meeting prizes will be offered for papers on the following subjects: Advance in practical fish cultural work; biological work connected with fish problems in general; and the solution of problems affecting commercial fisheries work. The competitive essays should be received by, at latest, August 20. Further information can be obtained from the executive secretary, Prof. R. C. Osburn, Ohio State University, Columbus, Ohio.

A PROPOSAL is on foot by the Swedish Linnean Society to restore the old botanic garden at Upsala, together with the house in it, the former residence of Carl von Linné, and subscriptions towards this object are solicited. Particulars of the suggested memorial can be obtained from the General Secretary of the Linnean Society of London, Burlington House, W.1, and donations sent to him or direct to the Swedish Linnean Society at Upsala.

ARCHITECTS, timber merchants, firms engaged in the building and furniture trades, railway companies, and, in fact, all users and consumers of wood, paper, and other forest products, should visit the British Empire Timber Exhibition, which is open to the public at the Holland Park Skating Rink, London, until July 17. The exhibition has been organised to display the forest wealth of the British Empire. Before the war the greater part of the immense importations of timber into the United Kingdom, some 10,000,000 tons annually, came from foreign countries, and many of these were closed during the war. This necessitated a considerable development of the sources of supply within the Empire and a greater demand on our home forests. The main object of the exhibition is a patriotic one, namely, to show that our timber requirements can be met in great measure from our Dominions and Colonies, thus extending Imperial trade. The specimens of timber include very many beautiful, valuable, and useful woods, of which only a few may be mentioned as examples, such as rosewood, satinwood, mahogany and its various substitutes, teak, greenheart, jarrah, ironwood, and the

numerous cedar woods. There is also a complete set of exhibits demonstrating the various uses to which timbers are put, as floors, panelling, veneers, plywood, furniture, and articles of everyday use. Many decorative exhibits are of great interest. The preparation of paper-pulp from bamboos is also shown. An exhaustive catalogue of the exhibits has been prepared. This gives both the botanical and trade names, the countries of origin, and names of shippers and importers. Each wood is fully described as regards its general characteristics, tension strength, and other useful data. The information in the catalogue has been compiled by the various Forest Departments of the Empire, and has a scientific as well as a commercial value.

THE half-yearly report of the Department of Civil Aviation on the progress of civil aviation from October, 1919, to March, 1920, contains many features of general interest. A very detailed survey of the results which have been achieved is given with regard to activities both in the British Empire and in foreign countries. Tabulated figures concerning the operation of air services between England and the Continent show that a slow but definite progress has been made. The importance of the International Air Convention is emphasised, and it is satisfactory to note that this Convention has now been signed by all the Allied Powers. The record of activities in foreign countries shows that many attempts are being made to develop commercial flying for both inland and international trade. France and Italy show the most promising results, and both are making efforts to exploit the possibilities of commercial aviation in Asia and South America. In late enemy countries many aviation companies have been formed to develop commercial flying, but no actual results have yet been achieved owing to the economic conditions prevailing. The first paragraph of the conclusion of the report is worthy of quotation as an apt summary of the present position. The Controller-General says:—"The discovery of a new method of increasing the speed of inter-communication has in the past generally indicated a fresh step in the march of civilisation. In aviation a means of transport has been obtained twice as fast as any other previously existing. The majority of countries which are imbued with the spirit of progress appear to realise that the future of aviation cannot be neglected, and by various methods, such as the creation of aviation departments, research, subsidies, and the conduct of experimental services, are striving to adapt aviation to commerce." Progress may be somewhat slow under the unsettled conditions which now prevail throughout the world, but there is little doubt that as the general economic situation improves, so will the advance of civil aviation become more rapid.

IN 1910 Dr. W. Max Müller was enabled, through the liberality of the Carnegie Institution of Washington, to visit the doomed island of Philæ, and to glean the epigraphic material left by the Berlin expedition. His immediate purpose was the decipherment of the famous bilingual inscriptions engraved on the walls of the large court between the first and the second pylons. This was exceedingly difficult, as the small, shallow-engraved signs become distinctly visible only during the short time of the day when they receive strong light. The Carnegie Institution has now published in a suitable style the result of Dr. Max Müller's labours. He gives complete facsimiles, transliterations, and translations of the inscriptions, and a learned introduction adequately reviews the historical information thus collected. The work is in every way creditable to the learned explorer and the Carnegie Institution.

IN the University of California Publications in American Archæology and Ethnology (vol. xvi., No. 6) Miss Lucile Hooper gives a valuable account of Shamanism among the Cahuilla Indians, one of the largest surviving tribes in Southern California. At one of their *fiestas* or annual rites the Shaman first took a dark substance from his breast; then "he reached into the fire with his foot and kicked out a few coals. One of these he picked up; it was about the size of a dollar. He immediately put it into his mouth. I was only a few feet away, and one of the sparks from his mouth, as he blew, fell on my hand, so I can testify that they were hot. The glow from the coal could be seen on the roof of his mouth. He swallowed it in about a minute. He swallowed three coals in this way." The dancing and singing are part of the rite. One man intended to eat the coals, "but his song had not gone right; he had forgotten part of it, no doubt due to some disturbing influence among those watching, or perhaps because of some spirit preventing his success. Since his song did not go right, he could do nothing." Other marvels of a similar kind are reported. "Another man saw a dove walking around; he raised his hands and clapped them together. The dove dropped as though dead, and blood flowed from its mouth. He then picked it up, threw it into the air, and it flew off as though nothing had happened." The report includes a full account of the religious and domestic rites practised by the tribe. Their pottery, which was of an interesting type, has now disappeared with the use of manufactured articles.

AN interesting report, by Mr. R. S. White, on an outbreak of pellagra amongst Armenian refugees at Port Said during 1916–17 has been published (Reports and Notes of the Public Health Laboratories, Cairo, No. 2, 1919). Much controversy has occurred with regard to the nature of this disease. In the outbreak in question the weight of evidence points entirely to a faulty diet as the causal factor, and the disease was eradicated from the camp by correcting this, all other conditions remaining the same. The diet at the time had an energy-value of about 2000 Calories only, which is very low, the protein amounting to but 46–48 grams, of which some 90 per cent. was derived from vegetable sources and was of low biological value. Maize had no direct causal relation to the disease. No protozoan or bacterial cause was discovered, nor could any connection with biting insects be found. The results of the inquiry are in accordance with the findings of Goldberger in the United States.

MR. FRANCIS HARPER, the assistant biologist of the United States Biological Survey, contributes to *Natural History*, the journal of the American Museum of Natural History, vol. xx., No. 1, an article of remarkable interest on the Okefinokee Swamp, which covers nearly seven hundred square miles of the south-eastern part of the State of Georgia. "It has no counterpart anywhere in the world." Drainage and the "lumber-man" threaten its existence, and unless the hand of the destroyer can be stayed it is certain that a considerable number of vanishing birds and beasts will be swept out of existence, this swamp being their last stronghold. In 1918 a society was formed for the purpose of securing the swamp as an educational and scientific reservation, and it is devoutly to be hoped that this aim will be secured; for such areas are of immense value, not only to the people of America, but also to the world of science at large.

WE have received from the American Museum of Natural History a brief preliminary report on the zoological collections made under its direction in the Belgian Congo territory during the years 1909–15. Of mammals, birds, and fishes respectively there are about 6000 specimens, of reptiles and batrachians nearly 5000, and of invertebrates more than 100,000. Material has been obtained for mounted groups of the okapi and square-lipped rhinoceros in their natural surroundings. There are also 3800 specimens illustrating anthropology. It is anticipated that the scientific papers on the collection will occupy twelve volumes of the Museum Bulletin, and a monograph of the okapi is being prepared for the Memoirs. There will also be a Narrative in two volumes and an Ethnological Album in three volumes. In consideration of the generous co-operation of the Belgian Government, a selection of duplicate specimens will be sent to the Congo Museum at Tervueren.

THE Crocker Land Expedition to North-West Greenland and Grinnell Land covered a district but little visited previously by naturalists. The mollusca obtained on the expedition by Dr. M. C. Tanquary and Mr. W. E. Ekblaw have now been described by Mr. F. C. Baker (Bull. Amer. Mus. Nat. Hist., vol. xli., 1919, pp. 479–517, pls. 25–27). No new species are claimed, but the number determined exceeds by four those obtained on the Nares Expedition of 1875–76, when thirty-four were enumerated by the late Mr. E. A. Smith. The more important species of Astarte and Buccinum have been figured, with the detailed sculpturing of the shells of the latter, but the chief interest in the collection is the number of species found in high latitudes and the extension of the northward range of several of the species. The same author (*tom. cit.*, pp. 527–39, figs.) also describes a number of fresh-water mollusca obtained by Prof. Frank Smith from various lakes in Colorado and Alberta. Fifteen species in all are dealt with, of which three are believed to be new.

A PRELIMINARY account of the Tasmanian skeleton of Nototherium, to which we referred in last week's issue (p. 559), was read before the Royal Society of Tasmania on May 10 by Messrs. H. H. Scott and C. Lord. The authors assign the specimen to *N. Mitchelli*, and consider that it was originally provided with a horn on the nose. They regard the Nototheria as the marsupial analogues of the rhinoceroses, some of them horned, others hornless.

THE atmosphere that surrounds the *Revue des questions scientifiques*, which is published at Louvain for the Société scientifique de Bruxelles, permits of the most liberal agnosticism in regard to scientific dogmas. Prof. Pierre Termier, in his address on "Les grands énigmes de la Géologie," delivered in the welcome epoch of recovery at Louvain in 1919 (*Revue*, vol. xxvii., p. 53, 1920), responds with his accustomed vigour to the invitation of his northern colleagues. His splendid oratory rings through these pages, in which he brings us face to face with the sphinxes that rise in the domain of geological inquiry and raise in the soul of the traveller "des pensées vertigineuses et des rêves sans fin." In his desire to show how much remains truly enigmatic, he makes no mention of tentative or even probable explanations, and his hesitating spirit before the evidences of organic evolution seems the pose of the courteous guest rather than the free expression of the prophet. For Prof. Termier, in his mere use of language, is a prophet and a power, and he hopes yet to see some secrets wrested from the earth as part of the general movement of humanity towards light and truth. On p. 149 of the same number of the *Revue* M. P. Teilhard de Chardin, who was present with the late Mr. Dawson at Piltdown, gives an excellent account of the human remains that have excited so much controversy, and he assures his readers that when palæontologists come to an agreement it is because they believe loyally and invincibly that their judgment has been based on truth. It is evident that these things still need saying, even in *sociétés scientifiques*, though we may have advanced some way from the scene so bitterly depicted by Barabino in his "Colombo deriso" at the Council of Salamanca.

THE New York Academy of Sciences has published two more parts of the results of its scientific survey of Porto Rico and the Virgin Islands (vol. i., part 2, and vol. iii., part 1). Porto Rico is largely and essentially a heap of volcanic *débris*, and Mr. Edwin T. Hodge attempts to unravel its geological history after making a detailed study and map of the Coamo-Guayama district. He also adds some useful notes on its mineral resources and hot springs. The limestones inter-stratified with the volcanic tuffs contain numerous fossil shells, which are, unfortunately, preserved only as impressions, but clearly represent several horizons between the Eocene and Miocene Tertiary. The shells are described in detail, with beautiful illustrations, by Miss Carlotta J. Maury, who makes some interesting remarks on their relation to the molluscs of existing seas. She points out that most of them are represented by living species which are evidently their descendants in the Antillean seas, but that several of the Tertiary genera have now completely disappeared from the Caribbean region, and exist only in the Pacific Ocean. The latter must have spread before the Isthmus of Panama arose, and it is

difficult to understand why they survived only on the western side of this barrier of land.

THE *Meteorological Magazine* for June deals with the recent disastrous flood at Louth as completely as possible at the time of going to press, and adds somewhat to the account in NATURE of June 10 (p. 468). The characteristic features are given of the hot weather experienced over England during the last week of May, which occasioned the development of numerous thunderstorms. A disturbance, centred over the Bristol Channel on the morning of May 29, traversed the Midlands during the day. Little or no rain fell on May 29 south of a line passing through Plymouth, Reading, and Lowestoft, and none was observed over the centre and west of Scotland. There was more than an inch of rain over the greater part of Lancashire, the West Riding of Yorkshire, Lincolnshire, and the east of Nottinghamshire. In Lincolnshire the rainfall was very severe. At Louth the fall was only 1·42 in., but at Elkington Hall, three miles to the west, the fall was 4·69 in., and of this 4·59 in. fell in three hours. At Hallington, about two miles south, 4·10 in. fell in two hours, when the gauge overflowed and the exact total fall was lost. Ten miles further south, at Horncastle, 3·95 in. fell in three hours. The magazine states that, according to the Borough Surveyor, the Lud stream, normally 3 ft. wide and 1 ft. deep, was swollen to a width of 52 yards and a depth of 50 ft. It appears that the stream was temporarily blocked with *débris*, and the flood was the result of the sudden breaking down of this obstacle. The periodical has a very suggestive and useful article on the ventilation of instrument shelters by the Director of Armagh Observatory. The general rainfall for May in England and Wales was 117 per cent. of the average, in Scotland 164 per cent., and in Ireland 145 per cent.

THE report of the Imperial Wireless Telegraph Committee (Cmd. 777, price 6*d*. net) contains an interesting review of the capabilities of different systems of wireless transmission for long-distance working, and forms a striking vindication of the powers of the thermionic valve, which it is proposed to employ as the sole means of generating the waves required for the chain of stations 2000 miles apart which are recommended. We admire the courage of the Committee in putting forward a system which, in its own words, "departs widely from the general direction of contemporary practice." It admits that "the objects desired might perhaps be secured by other and more conventional methods, but by none, in our opinion, not involving an immediate capital expenditure and a heavy annual loss which the scientific progress of a few years might well prove to have been unnecessary." Discussing the alternative systems, the Committee dismisses even the latest developments of the spark system as obsolete. The high-frequency alternator system it characterises as "costly, difficult to repair, and as yet insufficiently tested in prolonged operation." The arc system is described as "pre-eminent at the present moment among methods of long-range wireless transmission." Arcs of greater power than 250 kw., however, present elements of uncertainty, and apparently do not deliver to the aerial a greater effective current than those rated at lower powers. Although the valve system cannot show the same degree of accomplished results as any of the preceding, the Committee has evidence of such rapid advances now being made that it recommends its adoption without hesitation. It has already been found that a group of three glass valves delivering 2½ kw. into the aerial can effect communication over two thousand miles. Silica valves are now designed by means of which, with suitable grouping, 120 kw. will, it is hoped, be delivered into the aerial. Owing to the greater purity of wave-form of valve-generated over arc-generated waves, this arrangement should be considerably more effective than a 250-kw. arc, which does not really deliver more than 120 kw. into the aerial. There are several other advantages for valve working claimed in the report which we have not the space to mention here.

THE deposition of iron by electrolysis is a method which has lately been employed to a considerable extent for the purpose of "building up" worn and under-gauge parts of both aeroplanes and guns. The work, however, has not been done under proper scientific control, and not infrequently defects have manifested themselves in use in the iron thus deposited. A paper dealing with some of these was presented by Mr. W. E. Hughes at the recent meeting of the Iron and Steel Institute. In his capacity as chief research chemist to the Electrometallurgical Committee of the Ministry of Munitions, Mr. Hughes had opportunities of making extended observations upon the structure of the electro-deposited metal. He found that it was liable to contain pinholes, lumps, inclusions of foreign matter, cracks, and "quasi-cracks," and that a given specimen might present very marked differences of structure. He concludes that these defects may render the iron dangerous and unsuitable for engineering purposes, but that they arise from causes which can be largely eliminated by efficient control of the deposition process. It is generally assumed that electrolytic iron is a very pure product, but, as he shows, this is by no means necessarily the case. Further, it is usually assumed to be hard, and may indeed be so, though not always. Whether the hardness, when it occurs, is due to included hydrogen is a question which has not yet been settled. Mr. Hughes's investigation has proceeded sufficiently far for him to entertain decided doubts about this explanation.

MESSRS. DULAU AND CO., LTD., 34 Margaret Street, W.1, have just issued an important catalogue (No. 83) of secondhand books of science in the departments of ornithology, entomology, general zoology, geology and palæontology, geography, travel, and topography, botany and horticulture. Of the 1256 works listed many are out of print and not easily obtainable. The catalogue can be had free upon request.

ANOTHER of the useful catalogues (No. 403) of Mr. F. Edwards, 83 High Street, Marylebone, W.1, has reached us. It consists of descriptions of some seven hundred works relating to Central and South America, and should be of interest to many readers of NATURE.

Our Astronomical Column.

COMMENCEMENT OF THE GREAT PERSEID SHOWER OF METEORS.—The first Perseids probably appear at the end of June. They have certainly been observed in the first week of July. The earliest meteor of this shower, which has been doubly observed and the real path of which has been computed, was seen on July 8, 1918, by Mrs. Fiammetta Wilson and Miss A. Grace Cook. This year the moon left the evening sky about July 6, and the sky should be watched for traces of oncoming Perseids. At this time of the year meteors generally increase in numbers, and especially after the middle of July. The Perseids gradually become more abundant, and among the minor displays the chief ones are:

δ Aquarids	...	338° − 11°	o Draconids	...	291° + 60°
α Capricornids	.	303 − 11	λ Andromedids	.	350 + 51
θ Cygnids	...	292 + 52	ζ Pegasids	...	332 + 10
α Perseids	...	48 + 44	β Cepheids	...	333 + 71
α Cygnids	...	315 + 48	Lacertids	...	334 + 51

The radiant point of the Perseids moves N.N.E. as follows:—

July	8	...	9° + 46°	Aug.	1	...	33° + 55°
	16	...	16 + 49		9	...	43 + 57½
	24	...	24 + 52		17	...	54 + 59

THE EXPANDING DISC OF NOVA AQUILÆ.—Dr. Lunt contributed a paper on this nova to the June meeting of the Royal Astronomical Society which contains some interesting calculations on the rate of expansion. It was written before the recent Lick measures, which indicate a mean annual rate of increase of diameter of 1·9″, but he notes that Barnard's measures gave an increase of 2″ in the first six months, so that the rate may be diminishing.

Assuming the displacements of the edges of the bands in the spectrum to be a measure of the rate of expansion of the nova into a planetary nebula, Dr. Lunt found a radial velocity of 1500 km./sec., which would give a diameter of 1/100 light-year in a year, and would imply a distance of the nova of 1000 light-years.

According to Van Maanen's parallax of the ring nebula in Lyra (the largest nebula on his list), its diameter is 0·16 light-year. The expanding nova would attain this size in sixteen years if the rate were maintained.

Dr. Lunt notes that in the nova spectrum there are fine dark lines close to the normal positions of the H and K lines of calcium, which indicate a motion of approach to the sun of 17 km./sec., exactly the amount due to the sun's own motion. A similar feature has been noted in several other stars, and the suggestion made that these lines arise from clouds of very tenuous calcium vapour at rest in space. On this view these lines exist in the spectra of most stars, but are hidden by the star's own lines unless the latter are shifted by a large radial motion.

THE NEW MINOR PLANET GM.—It will be remembered that last January Señor Comas Sola, of Barcelona, discovered a new minor planet which was much brighter than most of those discovered in recent years, and was taken for a comet by some observers. The object was very well observed for several months, so that an accurate determination of the orbit is possible, and there is not much fear of its being lost again, as has happened to many of these little planets. The discoverer has now given it the name "Alphonsina," in double homage, as he says, to Alphonso X. of Spain, who was known as "the Savant," and to the present king, Alphonso XIII.

Annual Visitation of the National Physical Laboratory.

ON the occasion of the visitation of the National Physical Laboratory by the General Board on June 22, a large number of distinguished visitors availed themselves of the opportunity of inspecting the laboratory. The visitors were received by the chairman of the board (Sir Joseph J. Thomson) in the 7-ft. wind channel of the new aeronautics building, and afterwards visited the various departments of the laboratory, where exhibits illustrative of recent work were on view.

The exhibit in the engineering department was noticeable for the large number of machines for testing resistance to shock and to fatigue. The day is past when a simple test in tension is considered to yield sufficient data for structural material, and many other forms of test are now in use. One machine, designed by Dr. B. Haigh, subjects the specimen, by means of an alternating magnetic flux, to a maximum load of ±0·75 ton reversed two thousand times every minute. Another instrument, designed and constructed in the department, tests the endurance of stranded cables passing over pulleys. Among the impact testing machines, many of which were designed and made in the department, mention may be made of one in which both hammer and anvil are swung; by this means it is possible to obtain a striking velocity as high as 43 ft. per second. Machines for measuring the elastic limits of materials at high temperatures and for determining the efficiency of chains, gears, etc., were also among the exhibits.

In the aeronautics department various wind channels were operating, measurements of the performance of air-screws, the effects of aeroplane bodies on screws, and stability tests on bodies being carried out. Apparatus for measuring the skin-friction of air passing over thin plates was also exhibited.

Amongst the exhibits in the metallurgy department were a number of examples of failures of steel and alloy articles which had been sent in for investigation. Photomicrographs illustrating sections from these, as well as various sections under the microscope, were shown.

The representation of the constitution of a series of ternary alloys has never been an easy matter. Three models were exhibited which are designed to overcome this difficulty. They represent parts of the "diagram" for copper-aluminium-zinc alloys and a part of the aluminium-magnesium-silicon "diagram."

Considerable improvement has recently been introduced into the manufacture of thin-walled refractory tubing for thermo-couple protection and insulation; the apparatus with which it is made was shown in operation.

Demonstrations of the rolling of manganin, cast at the laboratory, into rods prior to wire-drawing were given in the rolling mill. Much valuable work has been done, in conjunction with the electricity department, on this metal, and it is now possible to produce manganin wire equal to the best pre-war material which was imported from Germany.

A modified form of the Shakespeare katharometer, used for measuring the permeability of balloon fabric, was in operation in the aeronautical chemistry division.

The exhibits in the Froude national tank can be divided into three heads. The first dealt with tests on the trim, the longitudinal stability, and the resistance of hulls of flying-boats. The second was work which was being carried out for Lloyd's Register in

connection with the design of oil-tankers to determine the stresses in the bulkheads of the oil compartments when the ship is pitching. The effect of varying the frequency of the pitch was studied. Thirdly, an apparatus was shown for testing the effects of a screw propeller working behind a ship. If we know the thrust which the screw must develop, and the velocity of the water behind the ship where the screw is working, relative to the velocity of the ship, then the ordinary data can be used to find the dimensions of screw required for a particular service. The object of the experiments is to find out these two factors.

The heat division of the physics department exhibited, amongst other things, a method of measuring humidity based on the property, shown by dry cotton, of absorbing moisture at a very high rate. Two similar coils of cotton-covered wire, one of which is coated with cellulose, are wound on to a single bobbin and connected up to the two sides of a Wheatstone bridge. They are dried by being inserted into a tube containing P_2O_5, a current being passed through them at the same time to ensure complete drying. The coils are then drawn out of the drying tube into the atmosphere the humidity of which is to be measured; the cotton on the uncoated wire absorbs moisture with extreme rapidity, which causes a rise in temperature of the wire, thus upsetting the balance of the bridge and deflecting the galvanometer.

Another exhibit consisted of a pointolite lamp for calibrating optical pyrometers. The special feature of this instrument is that the tungsten disc had a tungsten-molybdenum couple fused into it, by means of which it was possible to measure the temperature of the disc.

In the optics division of the physics department an apparatus was shown for measuring the coefficient of expansion of short specimens. It has been used lately for determining the coefficient of expansion of various glasses, and has given very interesting results. Interferometer tests and methods of measuring refractive indices were also shown.

One of the most interesting exhibits in the metrology department was a machine which was constructed to measure accurately to one-millionth of an inch. Slip-gauges are now made accurate to 1/100,000 in., and to test them it is advisable to have a machine which can read to one-tenth of this. The machine is used as a comparator, *i.e.* it measures the difference between the standard gauge and the one under test. The chief feature of the instrument is the complete absence of a micrometer head. The magnification is obtained partly mechanically, but mainly by a tilting mirror, which moves the image of a cross wire over a paper scale, giving a magnification such that a movement of ¼ in. over the scale corresponds to a difference in length of 1/100,000 in.

Another machine, for comparing end standards with line standards, can be used for lengths up to a metre. An important point about this instrument is that the two standards under comparison are in the same straight line.

A new type of micrometer for measuring the diameter of small balls, rollers, etc., was also shown, in which the readings are made on two parallel circles, one of which drives the other through epicyclic gearing; tenths and hundredths of an inch are read on one circle, and thousandths, ten-thousandths, and, by estimation, hundred-thousandths on the other. Both sets of readings are in line with each other, making the instrument very rapid to read. The position of contact is found by means of a small mirror moved by the tail-stock of the instrument.

The list of exhibits in the electricity department was large and interesting, but there is only space for reference to a very few of them. A considerable number dealt with photometry. Others were concerned with the temperature coefficient of manganin, with the measurement of frequency, efficiency, amplifying power, and characteristics of electric valves, and with a selenium-cell current regulator.

The Carnegie Foundation and Teachers' Pensions.[1]

TEACHERS' pension controversies are not confined to England. All our recent discussions of this subject have their counterparts in the United States, but there they are immensely complicated by the lack of co-ordination between the different States of the Union. Great diversity exists between the school pension systems which have been adopted or are under consideration, and no attempt seems to be made to bring them into relation one with another.

The universities and colleges (or such of them as are admitted into association) are the special province of the Carnegie Foundation for the Advancement of Teaching, and the fourteenth report of this body contains evidence of work of great value. Beginning in 1905 with an initial benefaction of ten million dollars, the endowment administered by the trustees has been increased by later gifts and accumulated interest to more than twenty millions. The object of the founder was to provide retiring pensions for teachers in universities, colleges, and technical schools in the United States, Canada, and Newfoundland "without regard to race, sex, creed, or colour"; but the granting of pensions does not by any means represent the whole of the activities of the trustees. To enable them to discharge effectively the duty laid upon them, they have felt compelled to conduct many inquiries and, when necessary, to offer fearless criticisms, and by these means they have undoubtedly exercised a powerful influence on the quality of higher education in America.

During the year 1918–19 the trustees disbursed in retiring and widows' allowances a sum of more than eight hundred thousand dollars. But in that year the old plan of granting such allowances was definitely abandoned in favour of a scheme under which the teacher himself is called upon to contribute towards the provision for his own retirement. It is of special interest to observe that, at the time when we in this country were adopting for school-teachers a national pension system on a non-contributory basis, which many university teachers wish to be extended to themselves, the Carnegie Foundation had come to the conclusion, as a result of thirteen years experience, that a "free pension" could not be a solution of the problem in a democratic country, but that the system must be contractual and rest upon the co-operation of the teacher and his college. This method, in the opinion of the trustees, is the only one that is "just, feasible, and permanent." To this end they organised a Teachers' Insurance and Annuity Association, in the control of which the teachers themselves will have real representation, and invited the universities and colleges to adopt pension schemes based on joint contributions by the teacher and his institution and worked by means of policies issued by the new association. The trustees continue the system of free pensions for those who were in the service of associated institutions before a certain date, but for others will content themselves with the pro-

[1] Carnegie Foundation for the Advancement of Teaching. Fourteenth Annual Report of the Chairman and of the Treasurer. (New York, 1919.)

vision of disablement allowances and the guarantee of a certain rate of interest on policies issued by the association.

We see, therefore, that, through the administration of a great private benefaction, there has been evolved in America a pension system which in general form is not dissimilar from the Federated Superannuation System for Universities and University Colleges in this country. There are, however, important differences. Whereas our federated system is in all essentials applied uniformly throughout the institutions concerned, the new system in America is subject to a variety of conditions as to the rate of contribution, the grades of staff admitted, and other qualifications as to length of service and amount of salary. Also, while some institutions make entrance to the scheme compulsory on all members of certain grades of staff, others leave it entirely to the option of the individuals. So long as this lack of uniformity continues, the simplicity of transfer from one institution to another, so valuable a feature of the English system, can scarcely be secured. It is further to be observed that the rate of contribution of the American college is never more than 5 per cent., as compared with the 10 per cent. now generally given by the English university; but against this must be put the fact that the policies issued by the American Teachers' Association are a little more generous in their terms than those of the insurance companies in our federated system.

A particularly useful section of the fourteenth report of the Foundation is that which deals with current pension problems both in America and in this country. It is here that we are most impressed with the almost chaotic condition of the pension arrangements in America as a result of the diversity of the State systems; but we are bound, on the other hand, to confess that our own Fisher scheme, while admitted to be generous, comes in for severe criticism, especially on account of its non-contributory basis and of the alleged weakness of the arguments used to support the adoption of a scheme of that character. Indeed, throughout the report the virtues of the contributory plan are urged repeatedly and with great insistence, and we cannot dismiss lightly the opinions of an authority occupying the unique position of the Carnegie Foundation. Though perhaps not within the sphere of immediate practical politics, it is legitimate to conjecture whether greater advantage would not result from a contributory system of pensions applied to the whole of our teaching profession than from a non-contributory system granted to a part of it. By the former plan we should recognise the essential unity of a great profession; by the latter we tend to separate it into parts and hamper the free interchange of teachers between one institution and another.

Those who are concerned in unravelling the knots in our own pension systems will find much suggestive material in this and previous reports of the Carnegie Foundation. But it is gratifying to feel that without the colossal munificence of a Carnegie we have yet reached a position which, with all its weaknesses, is still in many ways far in advance of that occupied by our Transatlantic cousins. Though we may regret lost opportunities, we realise that in a comparative sense we are not so badly off as we thought, and we are led to ask ourselves whether, after all, the scheme inspired by Sir William M'Cormick's Committee and designed by our universities in co-operation does not represent the best thing so far done in the matter of teachers' pensions.

In addition to its achievements in the pensions field, a valuable series of educational reports stands to the credit of the Carnegie Foundation. Under this head the papers contained in the fourteenth report on current tendencies in education, on legal education, and on the training of teachers are worthy of notice, though perhaps not so much for their discovery of new ideas as for their clear exposition of accepted principles and their straightforward description of the good and the bad in existing practice.

National Food Consumption in the United States.

PROF. RAYMOND PEARL has contributed to the Proceedings of the American Philosophical Society (vol. lviii., 1919, p. 182) an instructive article upon the consumption of foodstuffs in America from 1911 to 1918. He distinguishes between (1) primary foods, such as plant materials directly consumable by man, or animals not nourished upon primary foodstuffs, and (2) secondary foods, which cover the edible products of animals nourished upon primary foodstuffs. The necessary deductions were made for loss in storage, transit, etc., and for inedible refuse. The statistics are expressed in terms of metric tons of proteins, carbohydrates, and fats, and also in terms of Calories.

Broadly speaking, the salient feature of the analysis is the uniformity of consumption from year to year. The greatest relative advance (relative, that is, to the increase of population) was in the consumption of fat, the least in the consumption of protein, but the deviations from the line of increasing population are small.

Turning to the sources, it appears that 47 per cent. of the protein is derived from primary, and 53 per cent. from secondary, foods. Of fats, 82 per cent. are derived from secondary sources, while 95 per cent. of the carbohydrates come from primary sources. In terms of Calories, 61 per cent. of the intake is from primary foodstuffs.

These figures are not greatly different from the British returns analysed by the Food (War) Committee of the Royal Society. We derived 42 per cent. of our protein, 92 per cent. of our fat, and 35 per cent. of our energy from secondary sources. Put otherwise, we get fewer Calories and less protein, but more fat, from animal sources (exclusive of fish, which comes under primary sources in Prof. Pearl's classification) than the Americans. We should, perhaps, use the past tense in this comparison, since the British data do not refer to existing conditions.
